As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

QUALITATIVE PROPERTIES OF INTERNAL MOTIONS OF LAKE GENEVA (QUALITATIVE EIGENSCHAFTEN INTERNER BEWEGUNGEN DES GENFERSEES),
Ecole Polytechnique Federale de Lausanne (Switzerland).
V. M. Bohle, and C. Perrinjaquet.
Schweizerische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 196-218, October, 1983. 9 Fig, 3 Tab, 19 Ref.

Descriptors: *Water quality data, *Hydrologic properties, *Lake Geneva, Water currents, Hydrodynamics, Mathematical models, Model studies, Wind-driven currents, Wind waves, Waves, Internal waves.

The internal motions of the Lake Geneva are classified by means of the quotient 'Q' of the kinetic energies in alongshore and on-/offshore directions. Theoretical values for the frequency depending quotient are estimated for three simple model-geometries. A method of fourier spectral analysis was used which regards the limitations of the data set for the 1977/1978 measurement campaign. The internal motions of the Lake Geneva, as a response to external forcing, are relations of the frequency to the quotient of kinetic energies, which are, depending on the season, the slope and the width of the basin. 2A. General

A MODEL FOR ESTIMATING ONE-MINUTE RAINFALL RATES,
Air Force Geophysics Lab., Hanscom AFB, MA.
P. Tattleman, and K. G. Scharr.
Journal of Climatology and Applied Meteorology, Vol. 22, No. 9, p 1575-1580, September, 1983. 7 Tab, 7 Ref.

Descriptors: *Rainfall, *Model studies, Estimating, Multiple regression analysis, Mathematical models, Temperature effects.

A model for estimating one-minute rainfall rates uses stepwise multiple regression analysis. The model has six regression equations to estimate rates that equal or exceed 0.01, 0.05, 0.10, 0.50, 1.0 and 2.0 percent of the time during a month at a given location. Information required to make the estimates consists of monthly mean temperature, monthly mean precipitation, number of days in the month with precipitation (based on any of three threshold values that define a rainy day), and latitude. The model is not valid when the mean monthly temperature is less than freezing, when there is less than one rainy day in the month, or when a precipitation index is less than 2 mm/day. When there are between one and three rainy days during the month, the model may estimate rates for each of the exceedance levels, which when integrated, indicate a total rainfall two or more times greater than the monthly mean precipitation. Under these circumstances heavy, but infrequent, convective precipitation accounts for just about all of the precipitation in the month. Therefore, the most accurate estimates are for the two or three lowest exceedance levels, and significant rainfall may not occur more often than 0.5% of the month. These possibilities should be considered before accepting rate estimates in arid locations. (Murphy-IVI)

RESEARCH ON WATERSHED HYDROLOGY AT THE UNIVERSITY OF ILLINOIS,
Illinois Univ. at Urbana-Champaign.
B. C. Yen.
Journal of Hydrology, Vol. 68, p 3-17, 1984. 2 Fig, 1 Tab, 49 Ref.

Descriptors: *Research, *Watersheds, *Hydrology, Reviews, Mathematical models, Rainfall-runoff relationships, Statistical analysis.

Research on watershed hydrology at the University of Illinois started in the 1880's with the development of the Talbot waterway formula. In the following 60 years, studies on watershed hydrology were continued at Illinois on a relatively limited local scope. Activities on the subject were considerably expanded after Dr. Ven Te Chow joined the University in 1948. Activities in the lumped system approach, experimental investigation of runoff from rainfall, hydraulic based approach and analyses of spatial and temporal distributions of rainfall for watershed runoff are summarized. (Murphy-IVI)

MODELLING OF HYDROLOGIC PROCESSES IN A SMALL URBANIZED HILLSLOPE BASIN WITH COMMENTS ON THE EFFECTS OF URBANIZATION,
Tokyo Univ. (Japan). Dept. of Civil Engineering.
Y. Ando, K. Musiake, and Y. Takahasi.
Journal of Hydrology, Vol. 68, p 61-63, 1984. 16 Fig, 6 Tab, 3 Ref.

Descriptors: *Hydrologic models, *Urban runoff, *Urbanization, *Urban hydrology, Urban drainage, Urban watersheds, Rainfall, Evaporation, Groundwater movement, Groundwater recharge, Impervious area, Tokyo, Japan.

A clarification of the hydrologic processes was developed, based on a study of a small urbanized experimental basin in the Tama hills in the western suburbs of Tokyo, Japan. Impervious areas such as roofs and roads contribute to direct runoff. Infiltration areas do not contribute to direct runoff. Groundwater flow derives from the unconfined aquifer, and is in proportion to the second power of groundwater storage. Groundwater recharge is in proportion to soil-moisture excess. Evapotranspiration in the infiltration area of the urban basin is the same as that in the infiltration area of the natural basin, but the evaporation in the impervious area of the urban basin occurs to the extent of 2mm accompanied by rainfall. There were also urbanization effects on hydrologic processes. The contributing area to direct runoff is the saturated area for the natural basin, as against the impervious area for the urbanized basin. Urbanization effects on groundwater runoff are relatively small. Decrease in the ratio of the infiltration area to the catchment area, due to urbanization, has a large effect on the groundwater recharge process. Urbanization decreases evapotranspiration. RAINFALL-RUNOFF RELATIONSHIPS OF SOME CATCHMENTS WITH KARSTIC GEOMORPHOLOGY UNDER ARID TO SEMI-ARID CONDITIONS,
Ministry of Agriculture, Reclamation and Land Development, Benghazi (Libya). Dept. of Water and Soil.
M. R. de Vera.
Journal of Hydrology, Vol. 68, p 85-93, 1984. 3 Fig, 2 Tab, 10 Ref.

Descriptors: *Rainfall-runoff relationships, *Karst hydrology, Semiarid climates, Catchments, Arid climates, Mathematical equations, Rainfall intensity, Soil water.

Review of available consultant reports on water resources studies in the northeastern zone of Libya shows that fourteen catchments have good data on rainfall and runoff for analysis, but only eight wadis have sufficient flood data of at least eleven events for linear regression analysis. The prevailing surface geology of practically all the catchments is marly limestone, which is conducive to karstification processes. Since wadi flow is a direct response to rainfall, proper consideration of the other factors that affect runoff would result in a better functional relationship for runoff estimation. Results of regression analysis of rainfall and runoff show that the correlation coefficient ranges from 0.219 to 0.89. This means that 4.8 to 80.3% of the variation in runoff can be accounted for by the regression equation. The qualitative effect of karstification is reflected in the highly variable ratio between rainfall and runoff. The runoff coefficient, which is generally taken as the ratio of runoff to rainfall, should be used with caution for estimating historical or future runoff from catchments with karstic geomorphology, especially under arid to semi-arid conditions. A relationship expressing runoff as a function of rainfall intensity, rainfall duration, antecedent soil moisture, depth of unsaturated zone and degree of karstification should be investigated. (Baker-IVI)
W84-03338

APPLICATION OF ENVIRONMENTAL ISOTOPE TRACERS TO MODELING IN HYDROLOGY,
International Atomic Energy Agency, Vienna (Austria).
T. Dincer, and G. H. Davis.
Journal of Hydrology, Vol. 68, p 95-113, 1984. 11 Fig, 31 Ref.

Descriptors: *Hydrologic models, *Isotopic tracers, Hydrology, Groundwater recharge, Soil water, Evaporation, Climates, Precipitation, Tritium, Deuterium, Oxygen, Lakes, Swamps, Groundwater movement.

Chemical transport models employing the environmental isotopes found in natural waters are now practical due to advancements made in nuclear science and computer development. The most conservative tracers of water known are the heavy isotopes of hydrogen, deuterium and tritium. The heavy stable oxygen isotope, O-18, circulates in tandem with deuterium in the hydrologic cycle. Tritium fallout varies seasonally and annually in a systematic fashion and, due to its property of radioactive decay, is highly useful for dating time of recharge of soil moisture and groundwater. C-14 is valuable for tracing old groundwater due to its relatively long half-life of 5568 yr. However, detailed knowledge of the hydrochemistry of the system is needed for successful modeling. Deuterium and O-18 reflect the temperature at which precipitation condensed. They show pronounced seasonal variability and also the effects of altitude, latitude, distance from the sea, amount of precipitation, history of evaporation, and long-period climatic cycles. Principal areas of application of environmental isotopes to hydrologic modeling have been in soil moisture transport, modeling of mixing and evapotranspiration in large lakes and swamps, glacial-ice movement, groundwater flow, and transport of contaminants in groundwater. (Baker-IVI)

LONG-TERM HYDROLOGIC EVENTS FROM SHORT-TERM RECORDS,
N. Bethlahmy.
Journal of Hydrology, Vol. 68, p 141-148, 1984. 2 Fig, 1 Tab, 9 Ref.

Descriptors: *Hydrologic models, *Hydrologic data, *Flood forecasting, Mathematical models, Mathematical analysis, River forecasting, River flow, Flood flow, Low flow.

A new method based on ranks calculates the magnitude of hydrologic events associated with any desired probability. The system utilizes a transformation based on the median that yields positive values less than one. The method is substantiated through internal evidence. This method differs in a unique way from methods that define a distribution and then relate the probability of a variable to its deviation from the mean. Both the variable and its rank (its position in an ordered array) are transformed in an identical fashion. Because the time span N is brief, the hydrologist will normally be concerned with the magnitude of a variable at an extrapolated time T that is greater than sampling time N. As a result, n sub T for floods is always smaller than n sub N, and consequently q sub T will always exceed q sub N. If an extraordinarily large flood occurs during the base period N, then

extrapolated flood will be even larger. The reverse would occur for low flows. (Muphy-IVI)
W84-03340

STOCHASTIC NATURE OF OUTPUTS FROM CONCEPTUAL RESERVOIR MODEL CASCADES,
Waterloo Univ. (Ontario). Dept. of Civil Engineering.
T. E. Unny, and Karmeshu.
Journal of Hydrology, Vol. 68, p 161-180, 1984. 2 Tab, 14 Ref.

Descriptors: *Stochastic process, *Reservoirs, *Cascades, Model studies, Rainfall, Controlled storage, Stochastic hydrology, Evaporation, Catchment areas, Overflow.

Through consideration of one or more conceptual reservoirs to model the time distribution of outflows from catchments fed by rainfall, the characteristics of random rainfall inputs (including evaporation and catchment abstractions) are modified and catchment outflows are obtained with moment characteristics that are functions of the parameters describing the nature of the conceptual reservoirs. The stochastic differential equation describes the storage balance in the conceptual reservoir. The Nash cascade is expanded into a stochastic reservoir cascade. The variations in no more than two parameters representing the nature of the conceptual reservoir are sufficient to describe catchment outflows with widely varying moment properties and correlation characteristics. (Murphy-IVI)

IDENTIFICATION AND PREDICTION OF NONLINEAR HYDROLOGIC SYSTEMS BY THE FILTER-SEPARATION AUTOREGRESSIVE (AR) METHOD: EXTENSION TO HOURLY HYDROLOGIC DATA,
Tokyo Inst. of Tech. (Japan). Dept. of Civil Engineering.
M. Hino, and M. Hasebe.
Journal of Hydrology, Vol. 68, p 181-210, 1984. 16 Fig, 5 Tab, 9 Ref.

Descriptors: *Hydrologic models, *Rainfall-runoff relationships, Groundwater runoff, Surface runoff, Groundwater flow, Estimating, Predicting, Rainfall.

A direct extension of an earlier proposed method for the daily runoff data analysis may not be applicable to the analysis of hourly hydrologic data. A few modifications are suggested. The cut-off frequency to separate the total runoff time series into component runoffs was determined by the slope of the semi-logarithmic plot of the recession curve. Coefficients of the autoregressive moving average model applied to each of the subsystems were determined by the least-squares criterion from the recession period data when rainfall stopped. Nonlinear hourly hydrologic systems appeared easily and precisely identified by this method. Each subsystem of the surface runoff, interflow and groundwater runoff is linear. The nonlinearity of the rainfall-runoff system is caused mainly by the nonlinearity of the separation of rainfall into component rainfalls. The nonlinear separation rule of rainfall into rainfall components is derived from inversely estimated rainfalls. Time series of hourly rainfalls can be inversely estimated from hourly runoff by this method and it compares well with the observed effective precipitation time series regardless of the size of watershed. (Baker-IVI)

IDENTIFICATION OF A VOLTERRA SERIES CONCEPTUAL MODEL BASED ON A CASCADE OF NONLINEAR RESERVOIRS,
Technion - Israel Inst. of Tech., Haifa.
M. H. Diskin, A. Boneh, and A. Golan.
Journal of Hydrology, Vol. 68, p 231-245, 1984. 5 Fig, 3 Tab, 14 Ref.

Descriptors: *Rainfall-runoff relationships, *Reservoirs, *Model studies, Volterra series model, Rainfall, Runoff, Surface runoff, Cache River.

The Volterra series model based on a cascade of nonlinear reservoirs was originally proposed for the description of flood routing in open channels. Its possible application for modeling the surface runoff system was examined. The model fulfills all the conditions specified for kernel functions of conservative systems, as well as additional conditions derived from observations of the nonlinearity observed in surface runoff systems. Other features include the compactness of the model, the linkage between the two kernel functions that form the model, and the physical basis of the equations that describe the kernel functions. For the Cache River data used, the optimal values of the parameters of a model based on a cascade of linear reservoirs can serve as a good starting point for the search for optimal parameters for the model based on a cascade of nonlinear reservoirs. The number of reservoirs in the cascade is restricted to be an integer, and the number is relatively small. The number is the same for both the linear and the nonlinear models. (Baker-IVI)

HOW TO USE A SINGLE-PARAMETER CONCEPTUAL MODEL IN HYDROLOGY (QUE PEUT-ON FAIRE EN HYDROLOGIE AVEC UN MODELE CONCEPTUEL A UN SEUL PARAMETRE),
C. Michel.
Houille Blanche, No. 1, p 39-44, 1983. 9 Fig, 7 Ref.

Descriptors: *Hydrologic models, *Mathematical models, Rural areas, Drainage basins, Rainfall, Evaporation, Model studies, France.

A single parameter conceptual model was developed for representing the daily flows of the typical Orgeval basin in an acceptable manner. The basin used in this study is a typical example of the small rural basins found in the north of France. In the model, there are two 'reservoirs': the superficial reservoir (S) receives a fraction of the rainfall and is subject to evaporation; the routage reservoir (R) receives the other fraction of the rainfall and it is from here that water drains. The model was first tested using a single parameter. When a second parameter was introduced, the results were found to be better during a period of filling, but not as good during a period of control. Better results were obtained when the model was modified so that there are five modules functioning in parallel, each representing 1/5 of the sloping basin. (Moore-IVI)

SEASONAL FLUCTUATIONS IN THE CARBON DIOXIDE PARTIAL PRESSURE IN A CAVE ATMOSPHERE,
Pennsylvania State Univ., University Park. Dept. of Geosciences.
J. W. Troester, and W. B. White.
Water Resources Research, Vol. 20, No. 1, p 153-156, January 1984. 3 Fig, 21 Ref.

Descriptors: *Carbon dioxide, *Caves, *Seasonal variation, Tytoona Cave, Sinking Valley, Pennsylvania, Water flow, Partial pressures.

Many studies of the geochemistry of groundwater in carbonate terrains over the past decade have found it convenient and useful to characterize the water chemistry by a theoretical carbon-dioxide partial pressure. Carbon dioxide partial pressures were measured at 2 week intervals in a segment of a cave passage isolated by a water trap from mixing with outside air. The levels of CO2 fluctuated from 0.03 to 0.4 vol % being lowest in the winter and highest in the summer. The CO2 measured directly in the atmosphere and the CO2 partial pressure calculated from the pH and alkalinity of the underground stream have similar seasonal profiles. Evidence is strong that the CO2 concentration in both the conduit water and in the cave atmosphere is related to the growing season and to the type of soil and plant cover on the land surfce of the drainage basin nearby. (Baker-IVI)

MEIXNER FUNCTIONS FOR DERIVATION OF THE UNIT HYDROGRAPH,
Louisiana State Univ., Baton Rouge. Dept. of Civ Engineering.
V. P. Singh, and R. C. McCann.
Advances in Water Resources, Vol. 6, No. 3, 157-164, September, 1983. 14 Fig, 17 Ref.

Descriptors: *Rainfall-runoff relationships, *Ur hydrographs, Meixner functions, Watershed Rainfall, Runoff, Convolutions, Mathematic equations, Hydrographs, Linear programming.

The Meixner functions were used to relate t effective rainfall, the direct runoff and the ur hydrograph (UH) through linkage equations. Th linkage equations were then used to derive the U for given rainfall-runoff data on a small agricultu al watershed. The Z-transform was effectively er ployed to establish linkage equations relatin Meixner coefficients of the UH to those of th effective rainfall and the direct runoff. Meixn functions effectively derived the UH for the give watershed and synthesized the direct runoff hydr graph satisfactorily. Meixner functions produced UH which was not unduly sensitive to data erro These functions compare favorably with the lea squares and linear programming methods. (Bake IVI)

2B. Precipitation

SOME SPATIAL CHARACTERISTICS O DROUGHT DURATION IN THE UNITE STATES,
National Climatic Data Center, Asheville, NC.
T. R. Karl.
Journal of Climate and Applied Meteorology, V 22, No. 8, p 1356-1366, August, 1983. 9 Fig, 1 Ta 19 Ref.

Descriptors: *Drought, *Mathematical studie Statistical analysis, Correlation analysis, Palm Drought Severity Index, Precipitation.

The Palmer Drought Severity Index (PDSI), calculated from state averages of temperature an precipitation and from numerous single static analyses, demonstrates that droughts (as defined b the PDSI) persist longer in the interior of th United States than in areas farther east or we Contingency tables which use the PDSI as th predictor for the following one-month, six-mon and twelve-month precipitation anomalies (an also anomalies of precipitation minus potential ev potranspiration), are generally characterized b significantly greater skill in the interior portions the United States, confirming the notion that spe of abnormally dry or wet weather do have mo persistence in the Rocky Mountain and Hig Plains states than farther east or west. The for casts from the 'operational' PDSIs were not significant improvement from the precipitatio persistence forecasts. (Murphy-IVI)
W84-03043

RAINFALL ANALYSIS BY POWER TRAN FORMATION,
Mosul Univ. (Iraq). Dept. of Irrigation and Drai age.
H. Rasheed, A. S. Aldabagh, and M. V. Ramamoorthy.
Journal of Climate and Applied Meteorology, V 22, No. 8, p 1411-1415, August, 1983. 2 Fig, 5 Ta 10 Ref.

Descriptors: *Rainfall, *Measuring instrumen Mathematical studies, Power transformation, Pr cipitation, Rain gages.

Power transformation normalized the peak dai and peak monthly rainfall at various raingage st tions in Iraq. There were excellent correlatio between the coefficient of skewness (C sub s) and parameter for power transformation, coefficient kurtosis (C sub k) and the parameter for pow transformation, and between C sub s and C sub The relationship between C sub s and the param ter for power transformation will develop an es mation procedure for calculation of the transfo mation parameter. The method eliminates the u

of trial and error for estimating the parameter for power transformation. The annual series of monthly peak rainfall data shows that the log-Pearson Type III distribution offers estimates of rainfall similar to those of a power transformation. However, for data of less than 30 years period, a SMEMAX transformation gives estimates similar to those of a power transformation. A Gumbel distribution gives higher estimates. For daily peak rainfall data, log-Pearson Type III and Gumbel distributions give estimates close to those obtained by power transformation. SMEMAX transformation offers consistent lower estimates. PRECIPITATION OVER NORTHERN ITALY: A DESCRIPTION BY MEANS OF PRINCIPAL COMPONENT ANALYSIS,
SERMA, Milan (Italy).
F. Molteni, P. Bonelli, and P. Bacci.
Journal of Climate and Applied Meteorology, Vol. 22, No. 10, p 1738-1752, October, 1983. 10 Fig, 3 Tab, 35 Ref.

Descriptors: *Precipitation, *Italy, *Principal component analysis, Rainfall, Orographic precipitation.

The data sample used for the principal component analysis is formed by daily precipitation totals recorded at 35 rainfall stations during the periods October 1978-April 1979 and October 1979-April 1980. A spatial analysis is applied to the square roots of daily data and of their 3- and 5-day means, working on cross-product matrices obtained from both standardized and nonstandardized values. Four principal components (PCs) can be selected: the first is an index of the mean rainfall; the second represents the longitudinal differences; the third and fourth are representative of orographic anomalies. For daily data, these 4 PCs account for more than 80% of the total variance (since cross-product matrices are used in the analysis, the term variance must be interpreted as mean square value); this percentage is slightly higher working on nonstandardized values, but with standardized values the explained variance is distributed more uniformly among the 35 rainfall stations. Passing to 3- and 5-day means, the cumulative variance of the first 4 PCs increases; in particular, there is an increase for the first PC and a decrease for the others. These variations are compared with stability indices computed from the daily values of the PCs. The properties of high rainfall cases are well described by the PCs of 3-day values, whereas 5-day values are excessively smoothed. An orthogonal rotation, for which the criterion is based on physical considerations, is then applied to the first 4 PCs of nonstandardized daily values, the rotated patterns show a clear physical significance and can be related to different types of circulations in the lower troposphere over Europe. (Murphy-IVI)

THE UTILIZATION OF NIMBUS-7 SMMR MEASUREMENTS TO DELINEATE RAINFALL OVER LAND,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
E. Rodgers, and H. Siddalingaiah.
Journal of Climate and Applied Meteorology, Vol. 22, No. 10, p 1753-1763, October, 1983. 14 Fig, 10 Tab, 13 Ref.

Descriptors: *Nimbus-7, *Scanning multichannel microwave radiometer, *Rainfall, *Satellite technology, Remote sensing, Rainfall distribution, Rainfall intensity, Net rainfall, Meteorological data collection.

An empirical-statistical analysis using data from the Nimbus-7 scanning multichannel microwave radiometer (SMMR) detects rainfall areas over land. The addition of information from a lower frequency channel (18.0 or 10.7 GHz) improves the discrimination of rain from wet ground achieved by using a single frequency dual polarized (37 GHz) channel alone. Rain areas over land were determined from ground-based radar as were areas adjacent and upwind from rain areas. The probability for the mean vectors of any two populations being identical is less than 0.01 for classes sampled with surface thermodynamic temperatures > or = to 15 C, except for the rain over land and wet ground classes observed with the SMMR 37 GHz channel. None of the classes were signficiantly different for the classes with surface thermodynamic temperatures less than 15 C. For areas of large-scale heavy rainfall, a Fisher linear discriminant classifier determined the lower frequency SMMR channels were better able to delineate rain from wet ground than the 37 GHz channel. In areas of light rain and/or where the rain area did not fill the lower frequency instantaneous field of view the lower channels were not able to differentiate rain from wet ground. (Murphy-IVI)
W84-03147

SIMULATION OF A RAINFALL RECORD FOR THE SITE OF A NEW AGRICULTURAL DEVELOPMENT: AN EXAMPLE FROM NORTHERN SYRIA,
Reading Univ. (England). Dept. of Agricultural Botany.
M. D. Dennett, J. A. Rodgers, and J. D. H. Keatinge.
Agricultural Meteorology, Vol. 29, No. 4, p 237-258, 1983. 8 Fig, 4 Tab, 10 Ref.

Descriptors: *Rainfall, *Estimating, Syria, Model studies, Tel Hadya, Rainfall distribution, Precipitation.

A major concern among International Centre for Agricultural Research in the Dry Areas (ICARDA) scientists is the impact of weather, particularly rainfall, on crop productivity and, therefore it is important to know whether the experimental years to date were relatively wet or dry and how they fit into the long term expectations. Daily rainfall records for two sites in Nothern Syria are compared by fitting probability and frequency models to the observations. A model is interpolated for an experimental site at Tel Hadya, a site which is intermediate between the weather stations and for which long term measurements are not available. In dry years, at least, there may be some persistence of dryness over several months. Such long term effects are not included in the model, and thus it slightly overestimates rainfall amounts over long periods in dry years. It is possible to examine the rainfall patterns in recent years and place them in a long term context. (Baker-IVI)

SUPERCOOLED LIQUID WATER AND ICE CRYSTAL DISTRIBUTIONS WITHIN SIERRA NEVADA WINTER STORMS,
Bureau of Reclamation, Auburn, CA. Auburn-Folsom South Unit.
M. F. Heggli, L. Vardiman, R. E. Stewart, and A. Huggins.
Journal of Climate and Applied Meteorology, Vol. 22, No. 11, p 1875-1886, November, 1983. 12 Fig, 2 Tab, 15 Ref.

Descriptors: *Climates, *Clouds, *Precipitation, Snow, Sierra Nevada Mountains, Storms, Measuring instruments, Meteorological data collections, Physical properties.

Cloud physics data measured by aircraft during two successive winter field seasons (1978-79 and 1979-80) operating over the Sierra Nevada Range have been examined to determine the distributions of supercooled liquid water and ice crystals. The data has provided a close look at the supercooled liquid water content and ice crystal concentration in winter storms. The cellular echo type clouds clearly exhibit the most desirable characteristics of significant liquid water and relatively little ice. The area-wide and banded echo type clouds provide fewer instances of significant supercooled water and have an abundance of ice crystals. Liquid water maxima were found near the freezing level irrespective of percipitation echo type. Convective clouds provided the greatest likelihood of significant supercooled water. The largest water contents were observed at the greatest temperatures, usually zero to minus five degrees C. Such climatological information suggests that a weather modification program should concentrate primarily on the convective clouds in order to enhance snowfall. (Baker-IVI)

DROUGHTS AND FAMINES IN INDIA - A HISTORICAL PERSPECTIVE,
Meteorological Office, New Delhi (India).
P. K. Das.
Mausam, Vol. 34, No. 2, p 123-130, April, 1983. 3 Fig, 6 Tab, 13 Ref.

Descriptors: *Drought, *Water shortage, India, Drought index, Water supply, Stochastic hydrology, Model studies.

Droughts and famines are associated with periods of decline in food production. But, it is by no means clear that a drought was always a precursor of famine, because the latter , a situation of distress, might have been caused by lack of communications and other economic factors. Historical records suggest that there were 14 famines between the 11th and 17th centuries and another 12 famines in the 90 year period from 1869 to 1958. A sharp increase was noted in number between 1860 and 1908. Famines did not always coincide with years of drought. Many famines appear to have been caused by a lack of adequate communication. Drought indices have been developed in recent years which have noted droughts in 1951, 1965-66, 1972, and 1974. A stochastic prediction technique is based on autoregression for monsoon rainfall. This is a variation of ARIMA, which has been used in econometrics but has an interesting application in Meteorology. (Baker-IVI)

A THEORETICAL STUDY REGARDING HETEROGENEITY OF RAINFALL OVER MADHYA MAHARASTRA,
Meteorological Office, Poona (India).
A. K. Mukherjee, and K. C. S. Ray.
Mausam, Vol. 34, No. 2, p 167-170, April, 1983. 4 Fig, 1 Tab, 6 Ref.

Descriptors: *Rainfall, *Seasonal variation, Madhya Maharashtra, Western Ghats, Rainfall distribution, Model studies, Orography, Geography, Forecasting, India.

A line of delineation running north-south across the districts of Madhya Maharashtra was suggested while studying the normal rainfall over these districts. This line roughly distinguishes the rainfall distribution in the talukas to the west and the talukas to the east during the months of July and August. This heterogeneity of rainfall on both sides of the line of delineation is explained. A two dimensional model for orographic rainfall was used. The line of delineation was shown to roughly coincide with the place where the rainfall due to orography becomes nearly zero in the east side of the Western Ghats. Forecasts for rainfall in these two sections during July and August should be made from different considerations. (Baker-IVI)

THE SUB-DIVISIONAL RAINFALL DISTRIBUTION ACROSS THE WESTERN GHATS DURING THE SOUTHWEST MONSOON SEASON,
Meteorological Office, Poona (India).
G. Ramachandran, and A. K. Banerjee.
Mausam, Vol. 34, No. 2, p 179-184, April, 1983. 3 Fig, 3 Tab, 2 Ref.

Descriptors: *Rainfall distribution, Western Ghats, Monsoons, Wind, Tamil Nadu, India, Karnataka, Madhya Maharashtra, Rainfall.

The behavior of rainfall across the entire length of the Western Ghats has been examined for the monsoon season from June to mid-September over a period of 7 years from 1970-1976. The weekly rainfall between a pair of sub-divisions across and adjoining the Western Ghats during the southwest monsoon season is not necessarily positively correlated along the entire length of the mountain barrier. The relationship varies from one region to another. In the nothern sector between the pair of sub-divisions Konkan and Madhya Maharashtra the correlation coefficient is +.67. Moving southwards in the central sector the correlation coefficient between the pair of sub-divisions, coastal Karnataka and Interior Karnataka, remains positive but decreases to +0.30. But moving still southwards, into the southern sector, the relationship reverses and a negative correation of -.25 is obtained betwen Kerala and Tamil Nadu. The correlation coefficients are all significant at the 1% level. The changes in the correlation coefficients may be due to the presence of a low-level trough in the westerlies across Tamil Nadu during weak monsoon epochs. The relationship in the weekly rainfall between the pairs of sub-divisions across the Western Ghats may serve as a useful tool to predict rainfall distribution across different regions of the Ghats both in weak and strong monsoon phases. INTERPOLATION OF SHORT DURATION RAINFALL FROM 24-HOUR RAINFALL IN LOWER GODAVARI BASIN,
Meteorological Office, New Delhi (India).
D. V. L. N. Rao, S. C. Goyal, and S. N. Kathuria.
Mausam, Vol. 34, No. 3, p 291-298, July, 1983. 1 Fig, 5 Tab, 4 Ref.

Descriptors: *Rainfall, *Flood control, Godavari Basin, India, Floods, Estimating, Mathematical equations.

The short duration rainfall estimates of less than 24 hrs are essential for the design of spillways, culverts, road and railways bridges over small and medium catchments. This is accomplished from ordinary non-recording raingauges estimates short duration extreme rainfall for given return periods. Using data of 14 randomly selected self recording raingauges (SRRGs) from an already existing network of 17 S.R. raingauges in lower Godavari basin, regression equations were filled between a short duration rainfall estimate and a 24 hour rainfall estimate for a given return period. The coefficients of regression curve were worked out by the least squares method with the basin as a unit. Using these constants and coefficients, estimates of short duration in a problem area were made. The short duration rainfall estimates for 12 and 50 year return periods were computed for three existing SRRG stations which were not used in the computation of regression coefficients and four ordinary raingauge stations in and around the sub-zone. The errors, on comparison are within reasonable limits. The technique presented in the paper can be employed to estimate short duration rainfall from daily rainfall records for any area. (Baker-IVI)

DROUGHT SPELLS OVER NORTH-CENTRAL INDIA DURING THE 1979 SOUTHWEST MONSOON,
Cochin Univ. (India). Dept. of Marine Sciences.
H. S. Ram Mohan, P. Vaisala, and B. V. Appa Rao.
Mausam, Vol. 34, No. 3, p 299-302, July, 1983. 3 Fig, 1 Tab, 7 Ref.

Descriptors: *Drought, India, Moisture deficiency, Vegetation, Jamshedpur, Seasonal variation, India, Monsoons, Wind.

Widespread drought spells were noted over north-central India during the 1979 summer monsoon. An attempt is made to study the impact of drought conditions on the short period water balances of representative stations in the region. Cumulative deviation techniques were used to delineate and categorize the intensity and duration of drought spells. Ecologically, a mild drought of prolonged duration was more detrimental to vegetation than an intense drought of short duration. During the study period, there were prolonged drought spells of large and severe categories which were capable of crippling the economy of the region due to their adverse impact on agricultural production. The water balance procedure can be used to effectively delineate periods and intensities of droughts from an ecoclimate point of view. It is suggested that these techniques are more rational in delineating areas and periods of drought and categorizing their severities. (Baker-IVI)

SEMI-QUANTITATIVE PRECIPITATION FORECASTS FOR GOMTI CATCHMENT BY SYNOPTIC ANALOGUE METHOD,
Meteorological Office, Lucknow (India).
J. Lal, J. S. Day, and K. K. Kapoor.
Mausam, Vol. 34, No. 3, p 309-312, July, 1983. 1 Fig, 3 Tab, 4 Ref.

Descriptors: *Precipitation, *Forecasting, India, Gomti Catchment, Catchment areas, Rainfall, Rainfall distribution, Uttar Pradesh, Rainstorms.

At present, reasonably accurate qualitative rainfall forecasts for areas of interest can be given 24 to 28 hrs in advance, though for hydrological forecasting, these do not serve the real purpose since quantitative precipitation forecasts are required for rainfall run-off relationships. A simple method was sought for the semiquantitative advance assessment of areal rainfall for the Gomti river catchment in Uttar Pradesh. Different types of synoptic situations are correlated with their resulting rainstorms over the catchment to prepare synoptic analogues for forecasting the range of areal rainfall. If the assessment of the synoptic situation can be made correctly with the available data at the time the forecast is issued and the direction of movement of the rainstorm producing weather systems can be predicted on the basis of all available meteorological information, then semi-quantitative precipitation forecasts can be made fairly accurately 24 hr in advance using the analogues for the Gomti catchment as given. Similar analogues can be determined in respect to other river catchments. (Baker-IVI)

BASIN PRECIPITATION ESTIMATES BY BETHLAHMY'S TWO-AXIS METHOD,
California State Univ., Northridge. Dept. of Geography.
A. Court, and M. T. Bare.
Journal of Hydrology, Vol. 68, p 149-158, 1984. 3 Fig, 3 Tab, 12 Ref.

Descriptors: *Precipitation, *Bethlahmy's two-axis method, Hydrology, Climatology, Mathematical studies, Thiessen polygons, Isohyets, Isohyet planimetry, Elevation, Numerical analysis, Raingages, Depth-area-duration analysis.

Annual precipitation during each of five years over each of eight U. S. river basins, 800-4200 sq km, was estimated by Bethlahmy's two-axis method, Thiessen polygons, Isohyet planimetry, elevation weighting and simple averages. Elevation weighting had the largest values, isohyetal computations the smallest. Straight averages were sometimes high, sometimes low. Estimates from Thiessen polygons and the two-axis method tended to be in the middle of the estimates more so for the two-axis method. When gages are numerous and rather evenly spaced throughout a basin, the direct average of their annual catches is an adequate estimate of yearly basin precipitation. Bethlamy's two-axis method agreed with the other methods, but were easier to compute than by Thiessen polygons. The two-axis method requires identification of the circumcircle diameter, construction of two perpendicular bisectors, and measurement of angles. (Murphy-IVI)

ANALYSIS AND MODELING OF PALMER'S DROUGHT INDEX SERIES,
Purdue Univ., Lafayette, IN. School of Civil Engineering.
A. R. Rao, and G. Padmanabhan.
Journal of Hydrology, Vol. 68, p 211-219, 1984. 12 Fig, 7 Tab, 18 Ref.

Descriptors: *Drought, *Stochastic models, Model studies, Mathematical equations, Palmer's drought index, Kansas, Iowa, Forecasting, Rainfall.

The stochastic nature of yearly and monthly Palmer's drought index (PDI) series was investigated and characterized via valid stochastic models which may be used to forecast and simulate the PDI series. The monthly and annual PDI series for Iowa (1930-1962) and Kansas (1887-1962) are analyzed. The analysis of the PDI series indicates that long term oscillations and high persistence structure are important characteristics of drought indices and hence of droughts. The periodic behavior in drought index series is apparent in the conventional power spectra and also in the spectra computed by using high-resolution spectral methods. Rescaled range-lag characteristics also support these conclusions. Even so, the PDI series can be modeled by simple stochastic models which preserve the important statistical characteristics of the original data as demonstrated in this study. The simple models of PDI series developed can be used for generating synthetic PDI data and for forecasting PDI values which are used in agricultural planning and optimal operation of irrigation systems, respectively. A STOCHASTIC MODEL FOR A SMALL TIME-INTERVAL-INTERMITTENT HYDROLOGIC PROCESS,
Missouri Univ.-Rolla. Dept. of Civil Engineering.
C. D. Morris.
Journal of Hydrology, Vol. 68, p 247-272, 1984. 7 Fig, 8 Tab, 4 Ref.

Descriptors: *Stochastic models, *Precipitation, Rainfall, Model studies, Markovian precipitation distribution, Boneyard Creek, Morrow plots.

One of the major problems facing hydrologists is the lack of lang-term records of precipitation and streamflow. Simulation of hydrologic records by means of stochastic modeling is a commonly accepted statistical procedure to extend the record. A methodology is developed for the generation of intermittent small-time-interval (15 min) precipitation. The methodology consists of three components: a probabilistic wet-and-dry sequence component; a Markovian precipitation distribution component; and a regressive spatial-distribution component. The method is demonstrated by application to an actual precipitation network, the Boneyard Creek raingage network in Champaign-Urbana, Illinois. The trend in frequency of precipitation amounts from the 89 yr Morrow plots data are produced by the model using 13 yr of historical data. The model reproduces the mean and variance of storm precipitations, the storm lengths, the dry period lengths, the transition probability distributions of the precipitations and the autocorrelation structure of the network data. RECENT DEVELOPMENTS ON THE PROBABLE MAXIMUM PRECIPITATION (PMP) ESTIMATION IN CHINA,
East China Technical Univ. of Water Resources, Nanjing. Dept. of Hydrology.
Z. Daojiang, and Z. Jinshang.
Journal of Hydrology, Vol. 68, p 285-293, 1984. 4 Fig, 1 Tab, 8 Ref.

Descriptors: *Precipitation, *Estimating, China, Seasonal variation, Storms, Flood control, Probable maximum precipitation, Design criteria, Construction, Earth dams, Spillways, Reservoirs.

China is situated at the east of the Asian continent and in the subtropical and northern temperate zone of the Asian continental monsoon climate. Regional and seasonal characteristics of rain storms in China which introduce the most intensive rainfal

occurrences are examined. The techniques and practices involved in estimating the probable maximum precipitation from these storms is reviewed. Due to the lack of adequate streamflow data and abundance of heavy storms in China, it is very difficult and dubious to extrapolate a frequency curve to the long return periods required for a spillway of a major structure. In the design criterion of earth dams and/or rockfill dams (embankment) for reservoirs of major significance and also for important small dams the probable maximum precipitation and probable maximum flood should be used. Generalized charts of 24 hr point PMP have been developed. (Baker-IVI)

FOCUSING MECHANISMS IN THE TEXAS HILL COUNTRY FLASH FLOODS IN 1978,
National Oceanic and Atmospheric Administration, Boulder, CO. Environmental Research Labs.
F. Caracena, and J. M. Fritsch.
Monthly Weather Review, Vol. 111, No. 12, p 2319-2332, December, 1983. 27 Fig, 19 Ref. USAF grant AFOSR-79-0125.

Descriptors: *Focusing mechanisms, *Texas, *Hill Country, *Flash floods, Air masses, Storms, Thunderstorms, Rainfall intensity, Runoff volume.

During the early morning of 2 August 1978, a stationary thunderstorm complex drenched the Balcones Escarpment of Texas and unleashed flash floods in the Hill Country which killed 27 people and produced extensive damage. After the storm, an unofficial 24 h total of at least 79 cm of rain was observed near the town of Bluff (about 90 km northwest of San Antonio). Five distinct mechanisms or meteorological features interacted to focus and anchor the storm complex. An east-west oriented mesohigh outflow boundary was situated just south of the storm area while a rapidly moving ribbon of extremely moist boundary-layer air flowed toward the storm area from the southeast. An elevated warm, dry layer of air extended over the area east of the Hill Country and capped the southeasterly low level inflow. A deep vertical motion field associated with a midtropospheric short-wave trough advanced toward the Hill Country from Mexico, and the diurnal heating cycle with its associated production of thermally forced convective clouds ended. The juxtaposition of the first four mechanisms over the storm area in combination with terrain lifting and the termination of convection initiated by boundary layer heating resulted in a forced, stationary storm complex that produced catastrophic flash floods in the Hill Country. WATER POLLUTION ARISING FROM SOLID WASTE (COAL, FLY ASH, SLAG) DISPOSAL, AND MEASURES TO PREVENT WATER POLLUTION,
Electric Power Research Inst., Palo Alto, CA.
D. M. Golden.
Water Science and Technology, Vol. 15, No. 11, p 1-10, 1983. 10 Tab, 16 Ref.

Descriptors: *Water pollution prevention, *Waste disposal, Coal, Fly ash, Slag, Utilities, Environmental effects, Phytotoxicity, Groundwater pollution, Surface waters.

At the present, the annual world combustion of coal in electric power plants is about 2450 million metric tons coal eqv., resulting in the precipitation of 250-300 million tons of fly ash. Potential interactions of the environment with land-disposed utility wastes include: effects on local air quality, effects on soils and vegetation, phytotoxicity, groundwater effects, effects on surface waters, and disposal site washout. Both natural and engineered mitigating mechanisms are reviewed. These wastes are generally regulated as non-hazardous waste in the United States. Nevertheless, it is possible for non-hazardous waste to cause significant groundwater contamination. It is necessary for utility designers to consider the environmental risks and potential for liability when making engineering/cost evaluations of waste disposal options. (Baker-IVI)

THE METEOROLOGICAL OFFICE RAINFALL AND EVAPORATION CALCULATION SYSTEM - MORECS,
M. Field.
Agricultural Water Management, Vol. 6, No. 2/3, p 297-306, 1983. 4 Fig, 1 Tab, 8 Ref.

Descriptors: *Rainfall, *Evaporation, Soil water, Permeability, Winds, Temperature, Vapor pressure, Soil moisture deficiency, Water loss.

MORECS is an operational system using a suite of computer programs which has as its output estimates of soil moisture deficit, evapotranspiration and hydrologically effective rainfall plus several meteorological elements in the form of averages over 40 x 40 km grid squares superimposed over Great Britain. The output is disseminated to a wide range of customers on the day that MORECS is run. The operational system is described in two stages: meteorological data collection/storage, and data manipulation. Meteorological elements used by MORECS include rainfall, sunshine, windspeed, temperature, and vapor pressure. (Baker-IVI)

INFRARED REMOTE SENSING FOR MONITORING RAINFALL,
EROS Data Center, Sioux Falls, SD.
D. G. Moore, J. C. Harlan, J. L. Heilman, D. O. Ohlen, and W. D. Rosenthal.
Agricultural Water Management, Vol. 7, No. 1-3, p 363-378, 1983. 7 Fig, 15 Ref. National Oceanic and Atmospheric Administration grant NA 80 AA-D-00032. Geological Survey contract 14-08-0001-20129.

Descriptors: *Monitoring, *Rainfall, *Remote sensing, Precipitation, Spatial distribution, Soil water, TIROS-N, Satellite technology, Weather satellites, Infrared imagery.

Evaluations of thermal infrared satellite data from TIROS-N and the Heat Capacity Mapping Mission showed that rainfall distribution patterns could be reliably detected on images acquired up to at least 3 days after the event. The temperature relationship decreased 8 days after the event when soil variations influenced the signal. A time-series analysis reduced thermal variability normally observed over diverse landscapes and increased the sensitivity of the procedures. The method of repetitive low-resolution thermal observations could be operationally employed over large geographic regions with currently available satellite systems. The results would augment the existing raingauge stations by increasing the spatial sensitivity and the reliability of detection and mapping individual rainfall events. (Baker-IVI)

DISTRIBUTION OF MEAN ANNUAL PRECIPITATION ACROSS SOME STEEPLAND REGIONS OF NEW ZEALAND,
Ministry of Works and Development, Christchurch (New Zealand). Water and Soil Div.
G. A. Griffiths, and M. J. McSaveney.
New Zealand Journal of Science, Vol. 26, No. 2, p 197-209, 1983. 7 Fig, 2 Tab, 13 Ref.

Descriptors: *Precipitation, *Annual distribution, New Zealand, Rainfall, Spatial distribution, Mountains, Mathematical models, Tararua Range, Kaweka Range, Mt. Egmont, Hunua Range, Waitakere Range, Model studies.

The spacial density of raingauges in lowland regions of New Zealand generally is adequate to define the position of isohyets on the 1:500 000 scale maps. But in steepland or highland areas, expecially those exceeding 1000 m in altitude, rainfall information is sparse, and position of isohyets unreliable. The position of maximum rainfall coincides approximately with the crest of the principal ridge. On both flanks of a range, rainfall distribution is a well-defined function of ground elevation and also of horizontal distance from ridge crest. Ranges are distinguished into two types according to whether the elevation of their principal ridge crest is less or greater than 1300 m. For the former type rainfall gradient with respect to elevation at ridge crest is a positive increasing function of crest altitude, and for the latter type a positive decreasing function. A quantitative non-linear model describing a single-valued relation between rainfall and elevation at ridge crests and calibrated by data from 6 New Zealand ranges has high precision and the status of a structural relation. An extension to the model defines a single-valued relationship between rainfall and elevation for a given transect but is multiple-valued otherwise. Repeated application of the model and its extension to a steepland region allows improved construction of rainfall isohyets. (Baker-IVI)

PHYSICALLY MEANINGFUL PARAMETERS THAT CHARACTERISE RAINFALL TOTALS AND RAINFALL EXTREMES,
Meteorological Service, Wellington (New Zealand).
K. J. A. Revfeim, and H. S. Hughes.
New Zealand Journal of Science, Vol. 26, No. 4, p 443-445, 1983. 2 Tab, 5 Ref.

Descriptors: *Rainfall distribution, Poisson ratio, Mathematical studies, Precipitation, Storms, Seasonal variation, Distribution, Rainfall intensity.

Seasonal patterns of total rainfall and extreme rainfall events can be described in terms of physically meaningful parameters. The physical parameterization of rainfall data will distinguish between regions having the same mean rainfall but where one region has few events of large average amounts and another region has significantly more events of smaller average amount. Characterization of rain by parameters of a Poisson process of event occurrence and of an independent distribution of event size provides a better basis for comparison between sites or regions than the empirical statistical characteristics commonly used. 2C. Snow, Ice, and Frost

COMMENTS CONCERNING 'CONVECTION PATTERNS IN A POND',
Hawaii Univ., Honolulu. Dept. of Oceanography.
A. H. Woodcock, R. B. Lukas, and K. B. Katsaros.
Bulletin of the American Meteorological Society, Vol. 64, No, 3, p 274-279, March, 1983. 4 Fig, 11 Ref.

Descriptors: *Ice formation, *Albedo, *Snowmelt, *Temperature effects, *Convection, Ice, Ice water interfaces, Iced lakes, Ice cover, Snow cover, Ponds.

The article on 'Convection Patterns in a Pond' by K. B. Katsaros, Bulletin of the American Meteorological Society, Vol. 62, pp 1446-1453, 1981, stimulated the current authors to give further thought to their own and others' previous observations on this subject and specifically on direct and indirect convection effects. The weight of snowfall on ice-covered shallow ponds frequently causes upwelling of pond waters through leaks in the ice cover. The overall effect produced by dendritic melt centers surrounded by the patterned arrangement of altered albedo in the ice and snow on the pond suggests a pattern caused directly by differential melting of the ice and snow cellular convection from below. This pattern is also observed from plant stems projecting through the ice near shore, from openings along the shoreline, and from holes drilled in ice for experimental purposes. If the upwelling water temperature is too low for convection to occur in the water above the ice, then circular areas of melt and albedo changes might occur. The occasional regularity in the distribution of these patterns reveals the indirect role of convection cells in the water below the ice. (Geiger-FRC)

MICROCLIMATE AT ARCTIC TREE LINE 3. THE EFFECTS OF REGIONAL ADVECTION

ON THE SURFACE ENERGY BALANCE OF UPLAND TUNDRA,
McMaster Univ., Hamilton (Ontario). Dept. of Geography.
W. R. Rouse.
Water Resources Research, Vol. 20, No. 1, p 74-78, January, 1984. 2 Fig, 3 Tab, 7 Ref.

Descriptors: *Energy, *Advection, Heat flow, Tundra, Physical properties, Heat balance, Hudson Bay, Bays, Winds, Radiation, Climates, Frozen ground.

Energy balance components of net radiation, ground heat flux, and latent and sensible heat fluxes for upland tundra near the Hudson Bay coast at Churchill were measured continuously between April 25 and September 6, 1979. The measurements indicate a strong regional advective effect. In the postmelt period with cold onshore winds, which at Churchill blow from the north, sensible heating of the atmosphere was large, and heating of the ground was suppressed. For offshore winds from the south, ground heating was large and atmospheric heating suppressed. The net radiation and latent heat flux were little affected by wind direction. An atmosphere warming therefore should lead to a strongly increased ground warming by reducing the longevity of the Hudson Bay ice. It is also possible that the same advective factors that affect open tundra will also influence the forest at tree line, although at present no measurements of the atmospheric fluxes are available to support this thought. CLIMATIC EFFECTS ON THE RECESSION OF THE FRANZ JOSEF GLACIER,
Meteorological Service, Wellington (New Zealand).
J. W. D. Hessell.
New Zealand Journal of Science, Vol. 26, No. 2, p 315-320, 1983. 3 Fig, 3 Tab, 6 Ref.

Descriptors: *Glaciology, *Climatology, Glaciers, New Zealand, Recession, Snowfall, Rainfall, Temperature effects, Franz Josef Glacier, Meteorology.

Investigations of sequences of meteorological parameters observed over extensive periods on the West Coast of New Zealand have been compared with observations of the recession of the Franz Josef Glacier terminus. Independent investigations of the time series of precipitation, pressure gradient, and temperature have shown that prior to 1930, 3 years before the Glacier terminus commenced major recession, the 2 former parameters were significantly greater than in later years but that there has been no statistically significant increase in ambient temperature in the West Coast region. A depletion in the ice accumulation rate since 1930 has been the primary cause of the glacial recess there, and all glaciers with neves near the main divide, including those flowing eastward, have been affected. Temperature, precipitation, and other parameters such as radiation are not totally independent and during periods of near constant precipitation, short-period temperature anomalies may affect retreat rates of depleted glaciers. A significant advance of the Glacier could commence in 1983 or 1984 particularly in view of the heavy snowfalls in the springs of 1980, 81, and 82 and the wet, cold summer of 1982-83 on the West Coast. VARIATIONS OF THE STOCKING (TE WAE WAE) GLACIER, MOUNT COOK, AND CLIMATIC RELATIONSHIPS,
University of East Anglia, Norwich (England). Climatic Research Unit.
M. J. Salinger, M. J. Heine, and C. J. Burrows.
New Zealand Journal of Science, Vol. 26, No. 3, p 321-338, 1983. 15 Fig, 2 Tab, 26 Ref. DOE contract DE-ACO2-79EV10098.

Descriptors: *Glaciers, *Precipitation, *Temperature, *Stocking Glacier, *New Zealand, Climate, Principal component analysis, Multiple regression analysis.

A chronology of the fluctuating positions of the terminus of the Stocking Glacier, from 1869 to 1978 A.D., was derived from photographs. The changes in the glacier over the periods 1914-1974 and 1930-1974 are related with climatic variables by means of principal component regressions. The strongest associations of glacier variations for each of the periods examined are with smoothed monthly temperatures and precipitation data, with a lag of 2 and 5 years respectively. The similarity between each regression equations confirmed the stability of the method and identified temperature parameters as the more important factors correlated with glacier variations. Variation in Stocking Glacier terminus behavior accounted for by the 2 models is 83 and 71% respectively. (Author's abstract)

2D. Evaporation and Transpiration

DIRECT EVAPORATION FROM SOIL UNDER A ROW CROP CANOPY,
Agricultural Research Service, Akron, CO.
R. W. Shawcroft, and H. R. Gardner.
Agricultural Meteorology, Vol. 28, No. 3, p 229-238, 1983. 4 Fig, 15 Ref.

Descriptors: *Evaporation, *Soil moisture, *Canopy, Evapotranspiration, Mathematical equations, Lysimeters, Drainage, Flow, Surface water, Transpiration, Lysimeters.

Accurate measurements of soil evaporation under plant canopies are needed to refine the treatment of soil-surface wetness in irrigation-scheduling programs. Small lysimeters placed under a crop canopy to measure the soil evaporation component of evapotranspiration were constructed of rigid PVC pipe sections, 20.3 cm in diameter, and 20, 10, or 5 cm long. Water loss from the lysimeters was measured gravimetrically from composite 1-cm-increment cores sampled daily. The results reported are for two drying cycles of 16 and 13 days in July 1975 and 1976. In order for the lysimeters to behave as the surrounding soil, the water content of the lysimeters must be higher than the soil outside to compensate for changes under the natural conditions due to plant uptake, drainage and upward flow. Since the lysimeters depend on a set of compensating factors to directly measure E, estimates of E from them should be used with caution. A better use of the lysimeters would be to establish a relationship between lysimeter E and the surface soil water content and the use surface water content measurements to infer E. Several compensating errors must be involved in order for the lysimeters to simulate conditions of the actual soil surface. (Baker-IVI)

EVAPORATION FROM THE IRRIGATION WATER, FOLIAGE AND PANICLES OF PADDY RICE IN NORTH-EAST SRI LANKA,
Institute of Hydrology, Wallingford (England).
C. H. Batchelor, and J. Roberts.
Agricultural Meterology, Vol. 29, No. 1, p 11-26, 1983. 12 Fig, 21 Ref.

Descriptors: *Evaporation, *Canopy, *Vegetation effects, Plants, Evapotranspiration, Mathematical equations, Penman-Monteith equation, Rice, Transpiration, Panicles, Foliage, Irrigation water.

Fundamental to the design and operation of irrigation schemes is a knowledge of crop water use. The rate at which water is used by a particular crop is dependent on a number of factors which include age, variety, climate, soil-water availability, soil fertility, pests, diseases and cultivation, and irrigation practices. Combined measurements of leaf and panicle conductances with meteorological data in the Penman-Monteith equation were used to estimate transpiration from a paddy rice canopy. Evaporation from the panicles and the irrigation water accounted for a significant part of total evaporation from the paddy fields. The Penman-crop factor method of estimating paddy rice water used agreed well with the independent estimates of evapotranspiration here reported. After heading, the transpiration from the panicles accounted for 27% of the total transpiration of the canopy. The total evaporation for the 1981 cropping season from transplanting to harvest was 64 mm, of which 188, 395, and 63 mm were evaporated from the irrigation water, foliage and panicles, respectively. (Baker-IVI)

EVAPORATION FROM SCREENED CLASS A PANS IN A SEMI-ARID CLIMATE,
Agricultural Research Service, Fresno, CA. Water Management Research Lab.
T. A. Howell, C. J. Phene, D. W. Meek, and R. J. Miller.
Agricultural Meteorology, Vol. 29, No. 2, p 111-124, 1983. 9 Fig, 3 Tab, 15 Ref.

Descriptors: *Evaporation, *Screens, Semiarid lands, Water loss, Evapotranspiration, California, Climates.

Evaporation measurements from screened and standard Class A pans at two locations near Fresno, California were compared together and with potential evapotranspiration estimates, using two combination equations with climate data from the sites. The screen covering reduced the evaporation by 10% in a semi-arid environment. The evaporation reduction was largely attributed to differences in radiation interception by the screened pan. The evaporation from both type pans was highly correlated to potential evapotranspiration (ETO) estimates by the Penman and Van Bavel equations. Average annual pan coefficients for the open Class A pan were 0.81 and 0.91 for the screened Class A pan using the Penman equation calculations. Both pan coefficients were shown to exhibit a strong cyclical annual trend. When installed in standard grass weather station environments with adequate maintenance, evaporation pans can reliably estimate ETO, especially if the pan evaporation is averaged for time periods over 7 days. The screen covering served as a major obstacle to non-evaporative water losses from birds and animals commonly found at less protected sites, but the screen covering did not improve the correlations with potential evapotranspiration calculations. THE DIRECT EFFECT OF SHELTER ON EVAPORATION RATES: THEORY AND AN EXPERIMENTAL TEST,
Department of Scientific and Industrial Research, Palmerston North (New Zealand). Div. of Plant Physiology.
K. G. McNaughton.
Agricultural Meteorology, Vol. 29, No. 2, p 125-136, 1983. 2 Tab, 13 Ref.

Descriptors: *Evapotranspiration, *Windbreaks, Evaporation, Water loss, Shelterbelts, Advection.

Evaporation has been shown in previous work to be most strongly reduced during periods of strong sensible-heat advection. From theoretical considerations the use of an exchange flux as the measure of the effect of advection is proposed. The experiment of Miller is re-analyzed in terms of this exchange flux. In Miller's experiment evaporation rates from soybeans were measured directly using lysimeters, and secondary changes in plant growth and stomatal resistances were minimized. The exchange flux from Miller's lysimeter, located near the center of a semi-circular windbreak, was reduced to about half of its value in the open on most occasions. Thus the proposal that a windbreak can reduce the advective component of evaporation from a crop by reducing turbulent transport to the sheltered crop appears to be substantiated by theo-

retical and experimental evidence, if the advective component is identified as the exchange flux rather than the downward sensible heat flux. (Baker-IVI)

THEORETICAL AND MEASURED EVAPORATION RATES FROM AN EXPOSED PICHE ATMOGRAPH,
Purdue Univ., Lafayette, IN. Dept. of Agronomy.
K. T. Paw U, and M. Gueye.
Agricultural Meteorology, Vol. 30, No. 1, p 1-11, 1983. 2 Fig, 5 Tab, 22 Ref. NSF Atmospheric Sciences Section grant ATM-8021075.

Descriptors: *Evaporation, *Evaporimeters, *Measuring instruments, Energy budget, Temperature effects, Humidity, Wind speed, Radiation, Leaves, Water potential.

Evaporation and evapotranspiration influence the growth and even the survival of agronomic crops and livestock, forest species, and influence the water use strategies of human societies. A linearized energy budget for a leaf is used to predict the daily evaporation from a Piche atmograph. A one-to-one relationship was noted with observed evaporation, and accounted for 70-90% of the observed variance. Successful predictions were possible even when the meteorological data were taken at 12 hr intervals, although the most accurate predictions were based on data taken at 1 hr intervals. Sensitivity analysis predicts that Piche evaporation is strongly affected by air temperature, relative humidity, wind speed and long-wave radiation; albedo and short-wave radiation had lesser effects. The present study supports the idea that the Piche atmograph models the potential evapotranspiration of an individual leaf. The Piche evaporimeters and atmographs may be good analogs for potential leaf evapotranspiration because the equations used for modeling the Piche were originally developed for leaves. The definition used for potential leaf evapotranspiration is the evapotranspiration from a leaf when water is not limited, and when the physiological (mainly stomatal) resistance is effectively zero. SEASONAL ESTIMATES OF TRANSPIRATION FROM A MILLET CROP USING A POROMETER,
Nottingham Univ. (England). School of Agriculture.
S. N. Azam-Ali.
Agricultural Meteorology, Vol. 30, No. 1, p 13-24, 1983. 5 Fig, 4 Tab, 19 Ref.

Descriptors: *Transpiration, *Measuring instruments, *Crops, Millet, Porometer, Seasonal variations, Africa, Stomatal transpiration, Leaves, Water loss, Soil-water-plant relationships.

Water is one of the main constraints to agricultural production in many areas of the world since plant growth is closely related to transpiration. In west Africa, three populations of millet were grown to assess how growth was related to population and water supply. Stomatal resistance was measured with a porometer 3 times a day on 14 days. Boundary-layer resistance was estimated on the same days using blotting-paper replicas for the leaves, and wet- and dry-bulb thermocouples were used to determine concentration differences of water vapor. Changes in the mean rate of transpiration estimated from these quantities were strongly correlated with changes of green leaf area during the season. Seasonal changes of stomatal resistance were much less significant in determining the seasonal trend of transpiration rates. Estimates of water loss by transpiration agreed well with measurements of soil-water extraction obtained with a neutron moisture meter. This experiment suggests that the porometer is a useful alternative to the more established measurements of crop water use. Other useful information is obtained through the technique such as leaf temperature and vapor concentration differences between the leaf and the air. One major drawback is the time and labor spent in the field and on subsequent analysis of the data collected. A microprocessor incorporated in the porometer would allow semi-automatic calibration and enable direct calculation of transpiration per unit area of leaf, thus encouraging greater use of this technique. A DISCUSSION OF THE RELATIONSHIPS BETWEEN THE PRINCIPAL FORMS OF THE COMBINATION EQUATION FOR ESTIMATING CROP EVAPORATION,
Institute of Hydrology, Wallingford (England).
J. B. Stewart.
Agricultural Meteorology, Vol. 30, No. 2, p 111-127, 1983. 2 Tab, 26 Ref.

Descriptors: *Evaporation, *Vegetation, Forests, Canopy, Mathematical equations, Estimating.

To assist hydrologists and agronomists in estimating crop evaporation, the relationships between different forms of the combination equation are demonstrated by highlighting the assumptions used in their derivation and their data requirements. It is suggested that there is no formula which is superior in all situations. It is generally a compromise between data requirements and physical reality. By approaching the assumptions involved, an improved evaluation of the accuracy of the estimate of evaporation in each case can be made. Only the more complicated equation can give satisfactory estimates of the actual evaporation from all types of surfaces. For an area of low vegetation, which is rarely subject to significant soil moisture deficit, an estimate of the potential evaporation will provide a useful estimate of the actual evaporation. For areas of low vegetation and low rainfall, an estimate of the potential can still be used as an index and upper limit to the actual evaporation. For other vegetation types, and for forests in particular, the usefulness of an estimate of the potential evaporation is limited. If evaporation from a wet canopy is likely to be a sizeable component of the total evaporation, the potential evaporation may not even give a useful index of the actual evaporation. (Baker-IVI)

RESISTANCES TO EVAPOTRANSPIRATION FROM A ST. AUGUSTINEGRASS TURF CANOPY,
Texas A and M Univ., College Station. Dept. of Soil and Crop Sciences.
D. Johns, J. B. Beard, and C. H. M. van Bavel.
Agronomy Journal, Vol. 75, No. 3, p 419-422, May-June, 1983. 3 Tab, 17 Ref.

Descriptors: *Evapotranspiration, *Turf grasses, Resistance networks, Stenotaphrum, Canopy, Stomatal transpiration, Water potentials, Water conservation, Air temperature, Dewpoint.

In St. Augustinegrass (Stenotaphrum secundatum) turf under adequately watered conditions, evapotranspiration was influenced to a greater extent by environmental factors which were external to the plants rather than by disposition of leaf stomata. Using an Ohm's law analogue to define a resistance network for the turfgrass canopy, magnitudes of resistances to water loss were measured and compared. Internal resistance was defined as aggregate diffusive resistance of the foliage and was determined from porometer measurements of diffusive resistance of leaves. External resistance was defined as the sum of aerodynamic resistance and resistance to air mass exchange within the canopy and was measured by three different methods. Internal resistance was only one-fourth to one-half the external resistance. Under wind speed conditions of 0.6 m/sec, actual evapotranspiration rates of St. Augustinegrass were only slightly lower than potential evapotranspiration rates. Chemical or genetic control of stomatal resistance would not result in appreciable savings of irrigation water. (Wheatley-IVI)

STRESS MEASUREMENT USING FOLIAGE TEMPERATURES,
Guelph Univ. (Ontario). Dept. of Land Resource Science.
G. K. Walker, and J. L. Hatfield.
Agronomy Journal, Vol. 47, p 623-629, July-August, 1983. 6 Fig, 2 Tab, 31 Ref. Univ. of California Agric. Exp. Stn. project 3462-H.

Descriptors: *Water stress, *Leaf temperatures, Stomata, Stomatal transpiration, Water deficit, Water vapor, Crop yield, Kidney beans, Moisture.

The total (stomatal and aerodynamic) conductance for water vapor of a crop (g sub v) reflects the rate of crop production. Determination of g should therefore be valuable in predicting crop yield. With an energy balance approach to crop stress assessment, foliage-air temperature differences (Tf - Ta) may provide a beans of determining g sub v. This study models the response of Tf - Ta to environmental parameters and conductances, and then, in a field experiment with kidney beans (Phaseolus vulgaris L.) grown under two radiation regimes, determines g sub v using measured Tf - Ta values, and relates this to crop yields. Kidney beans ('Red Kidney') were grown on deep Yolo clay loam (Typic Xerorthent) at Davis, Calif., under normal irradiance and with irradiance reduced by 50%. Different stress levels (different g sub v) were established by varying time and frequency of irrigation. Foliage temperatures (corrected for emissivity and sky radiation), net radiation and wet and dry bulb temperatures were recorded daily at 1/2 to 1 h after solar noon through most of the growing season. Seed yields were measured at the end of the season. In the energy balance model and field data Tf - Ta is sensitive to air saturation deficit (0.16C mb-1) and to net radiation (0.5C/100 W m-2). Relative yields estimated as g sub v/g(max)sub v, with g(max) sub v determined from well-watered plots, agreed well with relative seed yields (r = 0.75). Major Tf - Ta responses to saturation deficit and net radiation

showed that Tf based crop stress estimates will not relate well to crop production unless these environmental parameters are accounted for, or unless they vary little between times of measurement. By using the energy balance, Tf - Ta measurements can be related explicitly to g sub v and, thereby, to crop production. (Murphy-IVI)

EVAPOTRANSPIRATION AND YIELD ESTIMATION OF SPRING WHEAT FROM CANOPY TEMPERATURE,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
R. A. Diaz, A. D. Matthias, and R. J. Hanks.
Agronomy Journal, Vol. 75, p 805-810, September-October, 1983. 5 Fig, 2 Tab, 21 Ref.

Descriptors: *Evapotranspiration, *Wheat, *Crop yield, *Canopy, *Temperature, Water stress, Plant water potential, Water management.

Canopy temperature indices are related to evapotranspiration (ET) and grain yield (Y) for many crops at various locations. Irrigation-water management methods have recently been proposed which involve the use of remotely sensed crop canopy temperature to assess actual crop water needs on a real-time basis. this study evaluates three indices at a location different from where the indices were developed. The indices were the stress-degree-day (SDD), temperature-stress-day (TSD), and the crop-water-stress index (CWSI), and were tested at Logan, Utah on spring wheat (Triticum aestivum L. var. Fieldwin). Planting dates were 14. Apr., 28 Apr., and 19 May 1980. Canopy temperatures in differentially irrigated plots (36 X 3 m) were measured by infrared thermometry at midday from growth stages of heading to maturity. Net radiation, wind speed, humidity, and air temperature data were collected. Neutron meter measurements were used to calculate ET. Summations of SDD and summations of TSD and mean values of CWSI were calculated. Linear regression analysis for each planting showed large goodness of fit (r squared > or = to 0.93) for Et vs. summations of TSD, and for Et vs. summations of SDD (r squared > or = to 0.86). Large r squared values were obtained with Y vs. summations of TSD and Y vs. summations of SDD data. For the combined data from all plantings, r squared ranged from 0.90 for the ET vs. summations of SDD data to 0.21 for the Y vs. summations of TSD data. Slopes and intercepts of individual regression lines were significantly (alpha = 0.05) different. Goodness of fit of relative ET deficit with mean CWSI for the combined plantings was r squared = 0.86, and for relative Y decrease with mean CWSI, r squared = 0.78. Results indicate that SDD may be most suitable for wheat yield assessment and water management in northern Utah. (Murphy-IVI)

TURFGRASS EVAPOTRANSPIRATION. I. FACTORS INFLUENCING RATE IN URBAN ENVIRONMENTS,
Colorado State Univ., Fort Collins.
C. M. Feldhake, R. E. Danielson, and J. D. Butler.
Agronomy Journal, Vol. 75, p 824-830, September-October, 1983. 9 Fig, 3 Tab, 13 Ref.

Descriptors: *Turfgrass, *Evapotranspiration, *Evaporation rate, *Urban areas, Water management, Poa, Festuca, Cynodon, Buchloe, Lysimeter, Shade, Nitrogen, Water use, Moisture, Plant water potential.

Evapotranspiration (ET) by turfgrass in urban environment is site specific and can vary considerably from what would be predicted from regional climate. A large degree of heterogeniety exists in residential microclimate and lawn management practices. The relative importance of these factors needs evaluation to aid in planning for efficient use of municipal water, half of which is applied to lawns in some western areas. This study, using small lysimeters, evaluated the relative effects of mowing height, N fertility, shading, grass species, and soil composition on ET. Kentucky bluegrass (Poa pratensis L. var. 'Merion') mowed 5 cm used 15% more water than grass mowed at 2 cm. Thirteen percent more water was used when 4 kg/1000sq m of N was applied each month during spring and summer compared to only one application for the season, applied in the spring. Evapotranspiration by grass in 1979 was essentially the same whether growing on a clay soil or on a sand-peat mixture; however, a 6% decrease occurred for the soil system in 1980. Evapotranspiration increased linearly with solar radiation when an advective component of energy, accounting for 35% of ET, was subtracted from all solar treatments. Kentucky bluegrass and tall fescue (Festuca arundinacea Schreb. var. 'Rebel') which are cool-season grasses, used over 20% more water than bermudagrass. (Cynodon dactylon L. X Cynodon transvaalensis Davy var. 'Tifway') and buffalograss (Buchloe dactyloides Nutt) which are warm-season grasses. (Author's abstract)

RELATIONSHIPS BETWEEN LEAF WATER POTENTIAL, CANOPY TEMPERATURE, AND EVAPOTRANSPIRATION IN IRRIGATED AND NONIRRIGATED ALFALFA,
Minnesota Univ., St. Paul.
B. S. Sharratt, D. C. Reicosky, S. B. Idso, and D. G. Baker.
Agronomy Journal, Vol. 75, p 891-894, November-December, 1983. 4 Fig, 19 Ref.

Descriptors: *Leaves, *Canopy, *Temperature, *Evapotranspiration, *Irrigation effects, *Alfalfa, Water use, Plant water potential, Moisture deficiency, Moisture uptake.

A prerequisite to exploiting potential production of any crop is to accumulate a knowledge of plant responses, whether the response is to climate, fertilizer, or water. Evaluations during the daytime were on a Waukegan silt loam soil (fine-silty over sandy or sandy skeletal, mixed, mesic Typic Hapludolls) with stress differences between irrigated and nonirrigated alfalfa (Medicago sativa L.). Canopy temperature (CT), evapotranspiration (ET), and leaf water potential (psi l), served as indicators of stress and were measured using an infrared thermometer, portable chamber, and pressure chamber, respectively. Canopy temperature and ET did not differ appreciably between irrigated and nonirrigated alfalfa in early morning, but after 0900 h and throughout the afternoon nonirrigated alfalfa had a higher CT and lower ET. Leaf water potential of nonirrigated alfalfa was consistently lower during the day. The maximum difference in CT, ET, and psi l between irrigated and nonirrigated alfalfa occurred at 1500 h where they equalled 2 degrees C, 0.2 mm/h, and 0.7 MPa, respectively. These stress differences reflected the differences in the plant available water of 280 and 60 mm (corresponding to 117 and 25% of extractable water) in the 1.83-m soil profile of the irrigated and nonirrigated plots, respectively. Nonirrigated alfalfa psi l declined at a faster rate as the peak stress period (1500 h) was approached; however, after this period a faster rehydration was observed for this treatment, as indicated by the relationship between psi l and ET. Despite the faster rehydration of nonirrigated alfalfa, the degree of hysteresis was greater for this treatment than for irrigated alfalfa. The relationship between CT and ET indicated a larger rate of change in CT prior to the peak stress period for nonirrigated as compared to irrigated alfalfa. After this time and until 1700 h, CT remained constant as ET decreased, indicating a decreasing ratio between ET and net radiation and thus greater restrictions on water movement through the plant, a direct cause of the hysteresis observed. (Murphy-IVI)

ALFALFA RESPONSE TO SOIL WATER DEFICITS. II. PLANT WATER POTENTIAL, LEAF CONDUCTANCE, AND CANOPY TEMPERATURE RELATIONSHIPS,
Minnesota Univ., St. Paul. Dept. of Agronomy and Plant Genetics.
P. R. Carter, and C. C. Sheaffer.
Crop Science, Vol. 23, No. 4, p 676-680, July-August, 1983. 3 Fig, 2 Tab, 26 Ref. OWRT, USDI grant 14-34-0001-1236-B158 MINN.

Descriptors: *Alfalfa, *Soil moisture deficit, *Plant water potential, *Canopy, *Temperature, Evapotranspiration, Irrigation, Stomatal transpiration, Water stress.

Information is needed on the regulation of water vapor loss and on the plant water status of alfalfa (Medicago sativa L.) subjected to soil water deficits. Our objective was to characterize diurnal and seasonal plant water potential (psi p), leaf conductance (Gl), and canopy temperature (Tc) relationships for field-grown alfalfa. Measurements of psi p, Gl and Tc were made hourly from sunrise to sunset on 13 clear days from 10 July to 2 October on alfalfa subjected to a range of soil water levels during vegetative, bud, and bloom growth stages. Plant water potentials of well-watered plants were -0.1 to -0.4 MPa at sunrise and declined to -0.8 to -1.2 MPa at midday. With soil water depletions, psi p declined rapidly (0.08 to 0.4 MPa/day) and diurnal psi p cycling continued. Under severe plant water stress psi p were below -2.0 and -4.5 MPa at sunrise and midday, respectively. The Gl under high moisture conditions reached a peak of up to 0.033 m/s at midmorning and decreased gradually until sunset. At moderate plant water deficits, Gl was greatest during low transpirational demand periods (early morning and late afternoon) and depressed at midday. Under extreme plant water stress, Gl remained at low levels (0.001 to 0.003 m/s) the entire day. Stomatal closure at midday resulted in Tc up to 8.5 degrees C higher for water-stressed vs. well-watered alfalfa. Leaf conductance declined linearly with decreasing psi p until psi p reached -2.5 MPa. Below a psi p of -2.5 MPa, Gl stabilized at low levels. Regression coefficients (slopes) of the Gl vs. psi p (< -2.5 MPa) linear regression equations were greatest when daily maximum air temperature (MAT) was high and decreased as MAT declined. Under nonlimiting soil moisture conditions, Gl declined linearly Tc was reduced. Growth stage and daily pan evaporation did not influence the Gl - psi p relationship. (Author's abstract)

BIOMASS PRODUCTION IN WHEAT IN RELATION TO EVAPORATIVE DEMAND AND AMBIENT TEMPERATURE,
Indian Agricultural Research Inst., New Delhi. Div. of Agricultural Physics.
N. V. K. Chakravarty, and P. S. N. Sastry.
Mausam, Vol. 34, No. 3, p 323-326, July, 1983. 2 Tab, 7 Ref.

Descriptors: *Evaporation, *Irrigation, Wheat, Crop production, Biomass, Ambient temperature, India.

Biomass production in three varieties of wheat grown under irrigated field conditions was linearly related to cumulative evaporation and accumulated heat units above a certain threshold value. The intercepts for biomass production evaluated from the regression showed that about 35 days are needed for crop establishment for the linear relationship to be true between biomass and cumulative evaporation/accumulated heat, corresponding to 82 mm of evaporation and 497 degree days respectively. Biomass production estimates at different levels of cumulative evaporation and accumulated heat indicated the possibility of using the regressions for relative assessment of varietal response to prevailing atmospheric demand representing potential water requirements and the prevailing thermal regime which should prove useful as an additional tool in crop planning. A SENSITIVITY ANALYSIS OF A NUMERICAL MODEL FOR ESTIMATING EVAPOTRANSPIRATION,
SAR, Inc., Riverdale, MD.
P. J. Camillo, and R. J. Gurney.
Water Resources Research, Vol. 20, No. 1, p 105-112, January, 1984. 9 Fig, 2 Tab, 11 Ref, 1 Append.

Descriptors: *Evapotranspiration, *Mathematical models, *Evaporation, Weather, Energy, Simulation, Sensitivity analysis, Wheat, Soil water.

A simulation approach has been used to study the sensitivity of evaporation, estimated with an energy and moisture balance model, to the meteorological data used to drive the model. The numerical model solves the surface energy balance equation. Daily evaporation is calculated by integrating the instantaneous fluxes. A Monte Carlo method is used to apply random errors to the meteorological data, and constant biases are also applied. This was done for both bare and wheat fields. Previous sensitivity studies have used analytical methods, ignoring the interaction of the meteorological measurements, their biases, and the feedback mechanisms which couple the energy and moisture fluxes. The method described here removes these restrictions and does not require linearity and differentiability in the evaporation estimation technique. The numerical method was shown to produce results generally similar to those expected analytically for random errors under near-potential conditions. Measurement biases produced larger errors in evaporation than random errors. The method will be applicable for dry conditions, where an analytical approach is not feasible. (Author's abstract)

MEASUREMENT OF EVAPORATION BY A VAPOR BUDGET TECHNIQUE,
Clemson Univ., SC. Dept. of Civil Engineering.
B. L. Sill, J. E. Fowler, and W. R. Lagarenne, Jr.
Water Resources Research, Vol. 20, No. 1, p 147-152, January, 1984. 8 Fig, 8 Ref.

Descriptors: *Evaporation, *Vapor budget, *Lake evaporation, Water vapor, Wind, Fetch, Water budget.

A vapor budget method for measuring evaporation from lakes is described. The technique involves measuring the upwind and downwind horizontal water vapor flux in the atmosphere for air that passes over an exposed water body. The difference in the two fluxes is shown to be equal to the surface evaporation. Instrumentation used to measure the required vertical profiles of horizontal velocity and water vapor density is also described. The method is applied on a small pond (57 x 57 m) in southern California, and measurements are compared with hourly water budget values of evaporation. Despite the short fetch, which limits the thickness of the vapor layer, comparison of the vapor budget values and those obtained by the water budget method is favorable. Results from a limited number of measurements on a larger lake (with a 600-m fetch) are also presented. It is estimated that at the present state of development, the vapor budget method is accurate to approximately 20% for small- to medium-sized lakes. (Author's abstract)

CROP WATER REQUIREMENTS FOR RAINFED AND IRRIGATED GRAIN CORN IN CHINA,
California Univ., Los Angeles. Dept. of Geography.
W. H. Terjung, H.-Y. Ji, J. T. Hayes, P. A. O'Rourke, and P. E. Todhunter.
Agricultural Water Management, Vol. 6, No. 1, p 43-64, 1983. 14 Fig, 2 Tab, 15 Ref.

Descriptors: *Corn, *Water use, *Climate, *China, *Korea, *Evapotranspiration, Climate, Crop yield, Irrigation requirements, Model studies, Rainfall.

A basic parametric crop water use model (WATER) that employs climatic and environmental data to calculate temporal and spatial water consumption for a variety of major crops was applied specifically for grain corn to the region of China and Korea to investigate the evapotranspiration (ET) demand on grain corn and the associated irrigation water applications necessary for optimal crop production. A network of 241 stations provided the seasonal climatic input. The climatic input consisted of data averaged over approximately a 20 year period. Among the results, highest ET under full irrigation (first harvest) occurred in the northwestern inland sections of China, whereas least ET was found for the southeast. Under rainfed conditions, the relationship became nearly inverse. In order to achieve optimum crop yields, about 1000 mm of irrigation water was needed in the northwest, contrasted with none required in the south and east of China. A sensitivity analysis was applied to determine the degree of error introduced by faulty or uncertain environmental input data. (Author's abstract)

A PRELIMINARY STUDY ON SCHEDULING IRRIGATION WITH CAN EVAPORIMETERS,
Andhra Pradesh Agricultural Univ., Hyderabad (India). Agricultural Research Inst.
M. Govind Reddy, Y. Yogeswara Rao, K. Subba Rao, and K. Ramaseshaiah.
Agricultural Water Management, Vol. 6, No. 4, p 403-407, 1983. 5 Tab, 3 Ref.

Descriptors: *Irrigation scheduling, *Evaporators, Irrigation efficiency, Wheat, Corn, Can evaporators, Hyerabad, India.

One of the most effective ways of increasing irrigation efficiency would be to provide farmers with a simple tool to schedule irrigation. Use of a class A pan by farmers is not practicable, but simpler evaporators, such as 'can' evaporators, may be useful. Field experiments were conducted in Hyerabad, India to study the relationship between a standard class A pan and a simple 'can' evaporator and to suggest irrigation scheduling for farmers using 'can' evaporators. The 'can' evaporators are made from one liter cans with a diameter of 10.5 cm, hung on posts. The bottom of the can was kept at a height of 30 cm above the crop level throughout the growing season. At the beginning of each irrigation, the water level in the can was brought to a reference point, 2.5 cm below the rim. Irrigation scheduling was carried out for wheat and maize grown in a semi-arid region, using cumulative pan evaporation (CPE). Scheduling of 60 mm depth of irrigation when CPE was 60 mm (IW/CPE = 1.00) was found to be optimum for wheat, while 60 mm depth of irrigation when CPE was 50 mm (IW/CPE = 1.20) was found to be optimum for maize. Cumulative evaporation from the cans (CCE), exposed above these crops, was recorded simultaneously. The ratios were higher over maize than over wheat. The CCE during the different stages of crop growth varied from 60.6 to 69.0 mm in wheat and from 51.5 to 94.0 mm in maize. The recommended depth of water in the can is obtained by multiplying the CPE with smoothed average CCE/CPE ratios. These depths may be marked inside the can for easy identification by the farmer. ESTIMATION OF EVAPOTRANSPIRATION AT ONE TIME-OF-DAY USING REMOTELY SENSED SURFACE TEMPERATURES,
California Univ., Davis. Dept. of Land, Air and Water Resources.
J. L. Hatfield, A. Perrier, and R. D. Jackson.
Agricultural Water Management, Vol. 7, No. 1-3, p 341-350, 1983. 5 Fig, 1 Tab, 20 Ref.

Descriptors: *Evapotranspiration, *Remote sensing, *Surface temperature, Energy, Aerodynamic resistance, Net radiation, Air temperature, Wind.

The estimation of evapotranspiration on a regional scale may be possible using remotely sensed inputs to surface energy balance models. Energy balance considerations lead to a relation that includes net radiation, surface and air temperatures, and an aerodynamic resistance, as inputs. The resistance term was examined as to its behavior under both stable and unstable temperature conditions, several surface roughness conditions, and at various windspeeds. The model shows that the evapotranspiration is higher than net radiation when the surface is cooler than the air and lower when the surface is warmer than the air. The aerodynamic resistance changes due to surface-air temperature differences play a substantial role in determining evapotranspiration. To test the model, evapotranspiration was calculated using remotely sensed temperatures, with the remaining inputs conventionally assessed. The calculations were made for a one-time-of-day period near midday, as would be required for a remote sensing technique, and were compared to lysimetrically determined evapotranspiration. The measured data were obtained at several locations in the Western United States, and were for a variety of crops. The good agreement between calculated and measured values indicates that the goal of developing techniques that produce accurate evapotranspiration estimates over large areas is attainable. (Author's abstract)
W84-03453

ESTIMATION OF DAILY EVAPOTRANSPIRATION FROM ONE TIME-OF-DAY MEASUREMENTS,
R. D. Jackson, J. L. Hatfield, R. J. Reginato, S. B. Idso, and P. J. Pinter, Jr.
Agricultural Water Management, Vol. 7, No. 1-3, p 351-362, 1983. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Remote sensing, *Evapotranspiration, Surface temperature, Model studies, Satellite technology.

The estimation of evapotranspiration (ET) on a regional basis requires remote sensing inputs. When obtained from air or space platforms, remotely sensed measurements are usually made at periodic intervals, and are essentially instantaneous in nature. A problem, then, is the estimation of daily values of ET from one time of day measurements. A technique is presented that allows the calculation of the coefficient necessary to convert one time of day measurements to daily totals. Input requirements are latitude, day of year, and time of day. This coefficient was applied to measured one time of day ET values and the results were compared to lysimetrically determined daily totals obtained at five locations and for four crops. One time of day ET was also calculated using an ET model that requires remotely sensed surface temperatures. These values were converted to daily totals and compared with measured values. The results indicated that reliable estimates of daily total ET from one time of day measurements could be made for cloud free days. For cloudy days the results are less reliable, but they suggest that estimates may be improved by considering the amount and temporal distribution of cloud cover. (Author's abstract)

2E. Streamflow and Runoff

LOW FLOW SYNTHESIS BY COMPUTER; PART ONE,
Shawinigan Engineering Co. Ltd., Montreal (Quebec).
D. Duba, and J. R. G. Pitchen.
International Water Power and Dam Construction, Vol. 35, No. 10, p 52-54, October, 1983. 4 Fig.

Descriptors: *Streamflow, *Computers, *Model studies, *Low flow, Design criteria, Construction, Flow, Bolivia, Rivers.

A streamflow synthesis computer model was applied to check the reliability of extremely low flow values, which occurred within a sequence of monthly flows used for firm energy estimates for a Bolivian river basin. The Streamflow Synthesis and Reservoir Regulation (SSARR) model provided a useful tool for this purpose. It was used to determine whether, based on the recorded rainfall data, the model would synthesize low flows of the same order of magnitude as those recorded at Talula. In the coarse of the drainage basin model calibration, elements of runoff were determined by a trial and error method aimed at the best fit of two years of recorded flow data. Consequently it was possible to obtain runoff characteristics of the drainage basin which were previously not defined. The model contributed significantly to the understanding of the mechanism of runoff generation and of the interaction among the drainage basin hydrological characteristics. The validation run proved satisfactory and helped reassess the critically low flow estimates which had been received earlier. (Baker-IVI)

LOW FLOW SYNTHESIS BY COMPUTER; PART TWO,
D. Duba, and J. R. G. Pitchen.
International Water Power and Dam Construction, Vol. 35, No. 11, p 43-47, November, 1983. 12 Fig, 1 Tab, 2 Ref.

Descriptors: *Streamflow, *Computers, *Low flow, Model studies, Rainfall, Snowmelt, Hydrologic models, Bolivia, Icla Dam, Dams, Talula.

A model is described which can be used to synthesize stream flow data where the available information is sparse or non-existent. The model, SSARR, is a mathematical hydrologic model of a river basin system throughout which streamflow can be synthesized by evaluating snowmelt and rainfall. In the case cited, only the rainfall was applicable. Two of the three basic components of the model were used; a generalized drainage basin model for synthesizing runoff from rainfall, in which the total drainage basin is separated into relatively homogeneous hydrologic units for independent analysis before summing; and a river system model for routing streamflows from upstream to downstream points through channel storage. The predictive validity of the model proved satisfactory, and it contributed greatly to quantification of the runoff generation mechanism and interaction between drainage basin hydrologic characteristics. EFFECTS OF LATE-GROWING-SEASON INUNDATION ON TREE SPECIES IN THE CENTRAL PLAINS,
Kansas State Univ., Manhattan. Dept. of Forestry.
M. W. Melichar, W. A. Geyer, W. L. Loucks, and F. J. Deneke.
Journal of Soil and Water Conservation, Vol. 38, No. 2, p 104-106, March-April, 1983. 1 Fig, 8 Ref.

Descriptors: *Floods, *Water stress, *Trees, Central Plains, United States, Flood control, Cottonwood, Hackberry, Honeylocust, Mulberry, Black walnut, Reservoirs, Vegetation.

Recreational sites are associated with reservoirs developed for flood control and/or irrigation throughout the United States. Planners in charge of tree planting programs on floodplains should consider submersion tolerance of the trees. Sixteen species of trees that were completely or partially submerged following late summer flooding in central Kansas were observed. Generally, the species performed as reported in the literature. There were, however, some exceptions. Cottonwood, hackberry, honeylocust, and mulberry, which are normally regarded as tolerant species, had high death and/or stress rates, while black walnut, normally an intolerant species, had only 4% of the observed trees die following inundation. Complete inundation increased the number of dead and/or stressed trees compared with partial inundation. Tree damage was affected not only by the degree of flooding but also by the dormancy state of the trees at the time of inundation. Thus not only the flooding itself, but the season in which it occurred was a significant factor. Species that had hardened before the flood were not affected as dramatically as those species still growing actively. (Baker-IVI)

FIELD VERIFICATION OF RUNOFF CURVE NUMBERS FOR FALLOW ROTATIONS,
Kansas State Univ., Manhattan. Dept. of Agricultural Engineering.
J. M. Steichen.
Journal of Soil and Water Conservation, Vol. 38, No. 6, p 496-499, November/December, 1983. 5 Fig, 1 Tab, 10 Ref.

Descriptors: *Runoff, *Rainfall-runoff relationships, *Erosion control, Erosion, Model studies, Tillage, Farming, Agriculture, Conservation tillage, Soil conservation.

Conservation tillage practices leave most or all crop residue on the soil surface. This leaves the surface rough. This condition promotes infiltration and reduces runoff. When water infiltrates the soil, it is available for crop use or groundwater recharge. Runoff contributes to surface water supply but, if excessive, causes flooding. A portable rainfall simulator determines Soil Conservation Service runoff curve numbers for fallow rotations at two locations in western Kansas. Field studies supported the estimated curve numbers obtained by reducing published curve numbers up to 10% for residue cover. Runoff estimates from stubble-mulched areas in northwestern Kansas by reducing curve numbers for residue cover appear reasonable. Although there was some variation due to deep tillage or large cracks, they were relatively short-term conditions that no doubt would change with the next significant rain. Reducing the curve number can reduce significantly the water yield in a semiarid watershed. At Colby, a storm in excess of a 10 year event is needed to yield 12.7 millimeters (0.5 inches) of runoff. MODEL OF MISSISSIPPI RIVER POOL: MASS TRANSPORT,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Civil and Environmental Engineering.
A. C. Demetracopoulos, and H. G. Stefan.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1006-1019, October, 1983. 13 Fig, 26 Ref.

Descriptors: *Computer models, *Mississippi River pool, *Mass transport, Hydrodynamics, Water quality, Dissolved solids, flow characteristics, Literature review.

A network of interconnected channels simulates the gravity and wind-driven flow in a river impoundment. A step-function specifies the forcing wind and a quasi-steady state simulation calculates the response for each timestep. A cells-in-series approach with appropriately sized subdivisions to account for dispersion simulates the transport of a conservative dissolved material through the system. The model is formulated and applied to Pool No. 2 of the Mississippi River, and compared with dye tracer data. A review of some field studies showing the importance of weather dependent processes in a shallow river impoundment is also presented. (Murphy-IVI)

POTOMAC RIVER STREAMFLOW SINCE 1730 AS RECONSTRUCTED BY TREE RINGS,
Lamont-Doherty Geological Observatory, Palisades, NY.
E. R. Cook, and G. C. Jacoby.
Journal of Climate and Applied Meteorology, Vol. 22, No. 10, p 1659-1672, October, 1983. 9 Fig, 4 Tab, 37 Ref. NSF grants ATM81-08459 and ATM81-16184.

Descriptors: *Potomac River, *Stream flow, *Tree rings, Low flow, Climate data, Climatology, Stream discharge, Meteorological data collection, Drought, Point of Rocks, Maryland.

A 248-year reconstruction of the low-flow (July, August and September) period, of the Potomac River indicates that the prolonged drought of the 1960s may have been the most severe since 1730. There appear to have been several long periods of about 50 years in length when flow was generally above or below the long-term median flow. The period from 1900 through 1950, which comprises most of the measured flow period, was generally above median. Long-period climatic shifts can have important water resource implications. The Potomac River streamflow at Point of Rocks, Maryland was reconstructed by using tree-ring chronologies from sites in or near the river basin. Canonical regression analysis was used to reconstruct simultaneously July, August and September discharge after screening all the tree-ring predictors. Verification statistics and cross-spectral analysis indicate that the average reconstruction of these three months is most reliable for periods longer than about six years and shorter than about three years. Spectral analysis of the reconstruction indicates the presence of a 15.7-year periodicity that warrants verification through examination of meteorological data, as well as through additional streamflow reconstructions in the region. The reconstruction offers climatologists a greatly lengthened data base from which hypotheses can be formulated and inferences drawn about past behavior of the climate system. (Murphy-IVI)

RELATIONSHIP OF RUNOFF AND SOIL LOSS TO GROUND COVER OF NATIVE AND RECLAIMED GRAZING LAND,
Science and Education Administration, Mandan, ND. Northern Great Plains Research Center.
L. Hofmann, R. E. Ries, and J. E. Gilley.
Agronomy Journal, Vol. 75, p 559-602, July-August, 1983. 4 Tab, 16 Ref.

Descriptors: *Runoff, *Soil erosion, *Ground cover, *Grazing land, Model studies, Erosion, Infiltration, Land reclamation.

Vegetation cover is a dominant factor in controlling runoff and water erosion from agricultural land and an important criterion for determining adequate reclamation of strip-mined land. A simulated rainfall study conducted near Center, N.D. determines the relationship of ground cover factors to runoff and soil loss. The point frame technique was used to estimate vegetation cover as measured by either the first contact (first hit) of the sliding pins with live vegetation, litter, or bare soil and rock or by a similar contact of the sliding pins at the soil surface (surface hit). Artificial rainfall was applied at the rate of 46 mm/h to 4.0 X 22.1 m runoff plots located on 9 to 12% slopes within reclaimed and unmined pastures. Reclaimed treatments were ungrazed or grazed at light, moderate, or heavy intensity plus vegetation and litter removed by burning. Native ungrazed plots had greater live surface cover than ungrazed or lightly grazed reclaimed plots but similar soil loss, runoff, and soil loss/ runoff ratio (SL/RO). Best fit techniques revealed some cover factors linearly related to soil loss, runoff, and SL/RO; others logarithmically related. Live surface cover estimates were poorly related to runoff and soil loss. Adequacy of soil protection can be best estimated by percentage of bare soil. Runoff or soil loss estimates were similar whether total cover was estimated by surface hits or first hits; however, surface hits were easier to determine in tall vegetation under windy conditions. The point frame technique is satisfactory for estimating whether the cover is adequate to maintain soil stability on reclaimed land or

native range. Its use can be extended to estimate ground cover in other erosion studies. (Murphy-IVI)

ALLOCHTHONOUS DRIFT FROM BACKWATERS TO THE MAIN CHANNEL OF THE MISSISSIPPI RIVER,
Luther Coll., Decorah, IA. Dept. of Biology.
J. W. Eckblad, C. S. Volden, and L. S. Weilgart.
American Midland Naturalist, Vol. 111, No. 1, p 16-22, January, 1984. 1 Fig, 3 Tab, 17 Ref. NSF grant SPI-8026430, Upper Mississippi River Basin Commission contract 889-305.

Descriptors: *Rivers, *Benthic environment, *Backwaters, Mississippi River, Drift, Allochthonous drift, Ecosystem.

The backwater lakes typically occupy shallow floodplain basins with mean depths less than 1 m, have short mean flushing times, trap both sediments and nutrients carried by influent water, and have relatively high rates of biological productivity. Blooms of algae and extensive stands of aquatic macrophytes are common in these lentic habitats. A number of sources suggest the importance of these backwaters to the productivity of the large river ecosystem, but studies intended to systematically evaluate the magnitude of backwater inputs to the main channel have not been conducted. Drift in Pool 9 of the Upper Mississippi River was sampled using paried nets suspended at 0.6 m and 2.7 m depths. Diel periodicity in numbers, differences in depth distribution, and differences between sampling months were noted for the drift. Drift coming through large side channels, draining backwater habitats, had mean numbers 10 times larger than that in the main channel of the Mississippi River. This allochthonous drift was largely in transport at night and reflected the backwater area drained and, in part, the benthic communities of backwater lakes. The pulsed inputs of allochthonous drift have been largely ignored and may influence the main stem of a large river ecosystem. (Baker-IVI)

SPATIAL HETEROGENEITY AND MODELS OF SURFACE RUNOFF,
Pittsburgh Univ., PA. Dept. of Civil Engineering.
R. C. Quimpo.
Journal of Hydrology, Vol. 68, p 19-28, 1984. 32 Ref.

Descriptors: *Spatial heterogeneity, *Model studies, *Surface runoff, Reviews, Watersheds, Mathematical studies, Mathematical analysis.

Spatial heterogeneity of the processes and parameters which determine surface runoff has given rise to different attempts to improve on the lumped system representation of the watershed. Techniques, ranging from the distributed formulation, component type lumped models and the use of partial source-area and geomorphological concepts are reviewed in order to identify possible areas of future inquiry. The methods tend to focus on different aspects of the problem as influenced by the resources available to the investigators in terms of data and computing capability and accuracy requirements as well as their analytical proclivity. The extensive documented evidence of spatial variability in most if not all of the parameters in the component models of the runoff process points to the requirement that a realistic model should allow for this heterogeneity. Constrained by the intractibility of a distributed model, it seems that a surrogate approach which tacitly allows for a distribution of parameters would be promising. The choice of an alternate mode must be tempered by the favorable likelihood of data availability to quantify the distribution. (Murphy-IVI)

THE KERNEL FUNCTION FOR WATERSHED RUNOFF MODELING,
Wuhan Inst. of Hydraulic and Electric Power Engineering (China).
C. Shengjia.
Journal of Hydrology, Vol. 68, p 29-37, 1984. 3 Tab, 9 Ref.

Descriptors: *Kernel function, *Watersheds, *Runoff, *Model studies, Rainfall-runoff relationships, Mathematical models, Unit hydrographs, Flood discharge.

The relation of the damping effect and lag time is an important law for the kernel function of a watershed. The input steps, the process of flow contribution to a watershed, is the curve of the damping effect for the reservoir regressive flow. The damping effect may be represented in the form of a logarithmic exponent function. Both the storage coefficient and lag time possess the effect of damping. A quantitative formula of the nonlinear kernel function is not only simple but possesses general meaning for the analysis of the nonlinear kernel. An improved version of Ding's variable unit hydrograph formula is designed to differentiate between the concepts of the linear and nonlinear reservoir. No matter what the process of the flow contribution for nonlinear or linear is, all are effected by the damping and lag time. (Murphy-IVI)

MATHEMATICAL MODELLING FOR FORMATION AND PROPAGATION OF FLOODS IN A DATA-DEFICIENT BASIN,
Bihar Coll. of Engineering, Patna (India). Dept. of Civil Engineeering.
T. Prasad, and O. N. Wakhlu.
Journal of Hydrology, Vol. 68, p 311-329, 1984. 3 Fig, 2 Tab, 8 Ref.

Descriptors: *Flood control, *Model studies, Floods, River basins, Runoff, Nash model, Storms, Manning's roughness coefficient, Mathematical equations.

A continuing study on the application of some modern concepts and techniques in hydrologic analysis to practical problems of a river basin is reviewed. Limitations imposed by the type, length, frequency and reliability of data as well as by computational facilities available are reported. Two inter-related processes investigated are the formation of floods and propagation of a flood flow down a river channel. For the former, the concept of the instantaneous unit hydrograph representing the basin response in transforming rainfall to runoff and the analysis based on the Nash model are applied. For the latter, a modified Muskingum method is proposed. An expression for variation of Manning's roughness coefficient with stage and a mathematical formulation for river rating for all stages of flow including flood flows have been obtained and tested for their validity for a particular section of the Jhelum River. HYDRAULIC GEOMETRY OF FLOODPLAINS,
Illinois State Water Survey Div., Champaign.
N. G. Bhowmik.
Journal of Hydrology, Vol. 68, p 369-401, 1984. 15 Fig, 7 Tab, 20 Ref.

Descriptors: *Flood plains, *Hydrology, Geometry, River basins, Streamflow, Runoff, Drainage areas, Illinois.

The shape, the size, the extent, and the spread of present-day floodplains are the end-products of the dynamics of streams and river systems which have been working on the earth's crust from prehistoric times. The hydraulic geometry of floodplains for various river basins was investigated to determine the variability and similarity of the hydraulic geometry relationships for these river basins. Data for 9 river basins in Illinois and 4 river basins outside the state were analyzed. The Horton-Strahler stream-ordering system and the concept of hydraulic geometry, which are valid for streams in the humid areas of the United States are also applicable to the floodplains of the rivers. The floodplains are carved in a systematic manner and the development of the floodplains follows a systematic pattern. The floodplain hydraulic geometry parameters of width, depth and cross-sectional area are related to the stream order and they increase in the downstream direction. The other parameters, sinuosity, incision, 100-yr discharge and drainage area are also related to stream order and they increase in magnitude in the downstream direction. The magnitudes of each hydraulic or geometric parameter within each river basin and for each stream order have frequency distributions varying anywhere from skewed to the left, to symmetrical, to skewed to the right. The frequency distribution of the hydraulic parameters for the mountainous stream for each stream order is generally nonskewed. In Illinois, streams in the nonglaciated or infrequently glaciated areas are more sinuous than those in the glaciated areas. (Baker-IVI)

CRUE: A MODEL FOR CALCULATION THE PROBABILITY OF RIVER FLOODING (CRUE: UN MODELE D'ESTIMATION DES PROBABILITES DES DEBITS DE CRUE),
J. Miquel.
Houille Blanche, No. 2, p 95-103, 1983. 10 Fig, 11 Ref.

Descriptors: *Mathematical models, *Probabilistic process, *Flooding, Flood flow, Model studies, Computer models, Computers, Analog computers, Flow characteristics.

Many factors are involved with flooding probability models. Using descriptive information (meteorology, human influences, types of floods), flow characteristics and historic records it is possible to develop a functional and applicable model for calculating the probability of river flooding. The model can directly compute a series of observed flows (or depths) for large or small flood basins. The use of this model is facilitated by the availability of a computer program and a practical estimating guide. The control must be stationary and contain homogeneity. (Murphy-IVI)

Houille Blanche, No. 2, p 119-126, 1983. 9 Fig, 5 Tab, 25 Ref.

Descriptors: *Prediction, *Low flow, *Streamflow, *Calcareous soils, *Tille River, Streamflow forecasting, Geomorphology, Karst, Karst hydrology, Mathematical studies, Graphical analysis.

While it is possible often to determine approximately the characteristic low level flows of a river at a hydrometric station, the transposition of these values to other points of the basin most often provides rough estimates, in particular because of the exchanges between the stream and sunken terrains. Transposition generally cannot be performed for water crossing karst sections by reason of the losses affecting the stream, which may cause it to dry up over very long periods. To solve this problem the flow is measured simultaneously at the hydrometric stations checking the flow at entry to the karst system, as well as at three points along the zone of losses. The threshold below which the flow entering the system is insufficient to prevent

the river from drying up, the characteristic flows at low water and the lengths of time the river remains dry for various return periods are defined for each site. (Murphy-IVI)

Houille Blanche, No. 2, p 131-140, 1983. 7 Fig, 4 Tab, 26 Ref.

Descriptors: *Runoff, *Watershed models, *Urban watersheds, Flood peak, Rainfall-runoff relationships, Runoff forecasting, Hydrographs, Literature review.

After a brief review of runoff models commonly proposed in the literature, some simple models are employed (Single linear reservoir model, Nash model, Kinematic model), in order to study the problems concerning peak flows in urban areas in Luzzi, Consenza, Italy. Different types of design rainfall are compared to determine the most effective method. A general indication on the application of these models and on the estimation of model parameters are inconclusive mainly because of insufficient data. (Murphy-IVI)

DISAGGREGATION PROCEDURES FOR GENERATING SERIALLY CORRELATED FLOW VECTORS,
Cornell Univ., Ithaca, NY. Dept. of Environmental Engineering.
J. R. Stedinger, and R. M. Vogel.
Water Resources Research, Vol. 20, No. 1, p 47-56, January, 1984. 1 Fig, 40 Ref. 1 Append. NSF grant CME-8010889.

Descriptors: *Disaggregation, *Flow vectors, *Statistical models, Covariance, Computer models.

Disaggregation models provide a straightforward procedure for dividing annual or seasonal flows among subperiods and dividing aggregate flows among subbasins. The structure of disaggregation models places severe constraints on the feasible values of the lagged covariance of generated flow vectors. A new and simple class of disaggregation models is presented which employ disaggregation model structure but allow the models' innovations to be serially correlated. These models can reproduce: the covariance matrix of the disaggregated flows; their covariance with the upper level flows; and reasonable approximations to the lag one covariance of the disaggregated flow vectors given the constraints imposed by a disaggregation approach. Whlie the mathematical formulation of disaggregation models is independent of the dimension of Z sub t and X sub t, those values have a tremendous effect on the computer storage space and processing capacity necessary to use such models. To disaggregate simultaneous annual flows at 10 gages to monthly flows wold result in a matrix containing 1200 elements and a covariance matrix with 7260 distinct elements. One can reduce the size of an all at once disaggregation model if one chooses not to reproduce the observed sample covariance among every monthly flow observed at every site. More appealing from a modeling and computational point of view is to use a staged disaggregation procedure. The Mejia-Rousselle disaggregation model in general fails to reproduce the anticipated variances and covariances of the disaggregated flows because the model and its parameter estimators are not self-consistent. RIVER FLOW RECONSTRUCTIONS AND THEIR USE, PART 1,
University of East Anglia, Norwich (England). Climatic Research Unit.
P. D. Jones.
Water Services, Vol. 87, No. 1053, November, 1983. 10 Ref.

Descriptors: *River flow, *Model studies, River catchments, Catchment areas, River Thames, River flow reconstruction.

In order to demonstrate the accuracy of river flow reconstruction, the Central Water Planning Unit catchment model is fitted to the River Thames to Teddington over the period 1951-76. The estimated river flows for 1885-1976 are then compared with the measured river flows. While the exercise did not demonstrate conclusively that the model reproduces the characteristics of the last one hundred years flow on the River Thames, the results are in broad agreement. A discrepancy in the results for low flow of 9 months duration, and also for longer durations, is due to the use of a catchment with a high groundwater contribution to the flow. (Baker-IVI)

REGIONAL VARIABILITY OF SOIL CHARACTERISTICS FOR FLOOD AND LOW FLOW ESTIMATION,
New Mexico State Univ., Las Cruces. Dept. of Crop and Soil Sciences.
A. Gustard.
Agricultural Water Management, Vol. 6, No. 2/3, p 255-268, 1983. 6 Fig, 2 Tab, 17 Ref.

Descriptors: *Flood control, *River flow, Estimating, Soil properties, Europe, Rivers, Spatial distribution, England, Rainfall, Model studies, Drainage, Permeability, Slope.

The applied hydrologist is required to estimate extreme flood and low river flows for the design of flood control and water resource schemes. Many projects are located where river flow data are absent and indirect estimates of flow statistics must be made, either by using a rainfall-runoff model or by using empirical relationships between river flow statistics and the physical and climatic characteristics of catchment areas. The importance of the role of soil and geology in influencing the low flow behavior of rivers is illustrated by referring to the Low Flow Study of the United Kingdom of 1980. A current investigation of floods in European rivers is also examined which requires the development of a map displaying the spatial variability of the hydrological characteristics of the soils of Europe. On the regional, national and international scale it is difficult to use detailed observations of the physical characteristics of soils because of the problems of taking measurements at a large number of sites and over long periods of time. More immediate improvements in flood and low flow estimation will arise from an extension of soil surveying together with feedback at the catchment scale from an analysis of hydrological data. The wider use of field measurements of soil properties will improve physically based models of catchment behavior and estimates of soil moisture deficits from climate data, thus assisting in developing models appropriate for regional flood and low flow estimation. A NUMERICAL PROCEDURE FOR THREE-DIMENSIONAL TRANSIENT FREE SURFACE SEEPAGE,
Arizona Univ., Tucson. Dept. of Civil Engineering and Engineering Mechanics.
C. S. Desai, J. G. Lightner and S. Somasundaram.
Advances in Water Resources, Vol. 6, No. 3, p 175-181, September, 1983. 15 Fig, 1 Tab, 14 Ref.

Descriptors: *Surface flow, *Finite element method, Seepage, Surface runoff, Runoff, Dams.

Most of the numerical solutions studies based on techniques such as the finite difference, finite element and boundary integral methods have considered two-dimensional plane and axi-symmetric idealizations. Few studies, though, have considered three-dimensional analysis including confined, steady free surface and transient free surface flow. This three-dimensional analysis is based on a time-integration solution of the governing differential equations of flow. The procedure is applied for solution of transient free surface flow including verification with respect to test results from a lab model. It is capable of providing values of fluid heads, velocities and plots of equipotentials in structures such as dams, slopes and wells. (Baker-IVI)

HYDROLOGY OF A BASIN WITH EXTREME RAINFALLS- CROPP RIVER, NEW ZEALAND,
Ministry of Works and Development, Christchurch (New Zealand). Water and Soil Div.
G. A. Griffiths, and M. J. McSaveney.
New Zealand Journal of Science, Vol. 26, No. 3, p 293-306, 1983. 7 Fig, 3 Tab, 37 Ref.

Descriptors: *Rainfall, *Hydrology, *River basins, Rivers, Runoff, Rainfall-runoff relationships, Cropp River, Alps, Mountains, Sedimentation, Floods, Vegetation, Precipitation, Rainfall intensity, Storms, Southern Alps, Erosion.

Cropp River, in the western Southern Alps, is a mountain torrent draining an area subject to frequent heavy rains. More than 100 storms occurred in 850 days of record. The rate of increase of rainfall depth with duration is independent of return period, and with respect to return period is independent of duration, for short return periods and comparatively short durations. Both rainfall isohyets and point rainfall intensities generally differ substantially from those predicted by national analyses of these parameters. Annual basin rainfalls could have been precisely predicted from annual mean water discharges. A high ratio of runoff to rainfall and a rapid runoff response to short-duration high-intensity rainfalls produce steep flood waves that rapidly translate down channel. More than half the runoff from storm rainfalls leaves the basin within an hour of rainfall ceasing. Specific annual suspended sediment yield could have been predicted approximately. Bedload is a small proportion of the total yield and it may move down channel in large floods as waves. The extreme precipitation is the dominating influence on the hydrological characteristics of upper Cropp basin and on the development of soils, vegetation, and geomorphology. (Baker-IVI)

THERMAL IMPACT OF RESIDENTIAL GROUND-WATER HEAT PUMPS,
Missouri Univ.-Rolla. Dept. of Geological Engineering.
D. L. Warner, and U. Algan.
Ground Water, Vol. 22, No. 1, p 6-12, January-February, 1984. 8 Fig, 3 Tab, 7 Ref.

Descriptors: *Thermodynamics, *Groundwater, *Model Studies, *Groundwater potential, Simulation, Mathematical models, Hydrothermal studies, Thermal properties, Thermal pollution, Heated water, Heat transfer, Aquifers, Water reuse, Water cooling, Well water, Test wells, Pump wells, Heat pumps, Columbus, Ohio, Houston, Texas, Concord, New Hampshire.

Due to rising energy costs, ground-water heat pumps have come to be regarded as viable means of reducing space heating and air conditioning costs. A residential water-source heat pump is simply a device which exchanges heat between a source and a sink. A computer simulation quantifies the potential thermal impact of residential water source heat pump usage on groundwater aquifers. Weather data for nine locations throughout the country estimated the energy requirements for heating and air conditioning a typical resi-

dence. These energy requirements were translated into the volumetric water demands for a selected heat pump at each location. A representative model aquifer defined and characterized along with the heat pump water requirements and design (difference between inlet and outlet water temperature) identifies the important paramenters that contribute to heat transfer and models the movement of the thermal front resulting from injection of heat pump discharge water. The major factor that determines the heat pump thermal impact was the net amount of heat injected into, or removed from an aquifer. Other significant factors included well design, heat pump design, and physical properties of the aquifer such as thickness, porosity and dispersivity. In climates where winter heating demand is very nearly equal to summer cooling demands, the injection of heat pump discharge water did not cause any significant modification of the ambient model aquifer temperature. However, in hot or cold climates where air conditioning or heating demand dominates, measurable thermal changes occurred in the model aquifer. The maximum temperature change to be expected is fixed by the heat pump which is, at most, 20 degrees F for existing commercial heat pumps. The exception to this would be cases where interference between injection and production wells occurs, leading to recycling of water between them. There was good agreement between model-generated results and the data taken from an operating heat pump installation. (Murphy-IVI)

FLUORIDE IN THE GROUND WATER OF NORTHEASTERN OHIO,
Akron Univ., OH. Dept. of Geology.
R. G. Corbett, and B. M. Manner.
Ground Water, Vol. 22, No. 1, p 13-17, January-February, 1984. 5 Fig, 3 Tab, 18 Ref.

Descriptors: *Fluoride, *Groundwater, *Ohio, *Drinking water, Chemical analysis, Bedrock, Well water.

It is widely recognized that about 1 mg/l of fluoride is the optimum content of drinking water for proper dental health. Based upon the annual average of maximum daily air temperatures in the Akron area, the recommended control limits for fluoridation are 0.8 and 1.5 mg/l, with an optimum value of 1.1 mg/l. Fluoride contents range from <0.05 to 5.9 mg/l based upon 255 water samples collected from wells in nine counties of northeastern Ohio. Only 16 samples had fluoride contents exceeding 1 mg/l, and all are from the southern trio of counties. Furthermore, all samples high in fluoride are from wells close to or penetrating the contact between the Allegheny and Pottsville Formations. Data from a line of 34 wells for which logs were obtained indicate that high fluoride water occurs in either the lower part of the Allegheny Formation, or more probably, in the upper part of the Pottsville Formation. Ground waters high in fluoride are related to the bedrock geology. Fluoride data, particularly in the area of potentially high values, are important to health professionals in the prescription of fluoride supplements for children. Such prescriptions should be made only after the water has been tested. (Murphy-IVI)

THE INVESTIGATION OF AQUIFER PARAMETERS USING MULTIPLE PIEZOMETERS,
North West Water Authority, Warrington (England). Rivers Div.
S. Walthall, and J. A. Ingram.
Ground Water, Vol.22, No. 1, p 25-30, January-February, 1984. 6 Fig, 1 Tab, 6 Ref.

Descriptors: *Piezometers, *Aquifer characteristics, Geohydrology, Boreholes, Pumping tests, Groundwater storage, Geophysics, Confined aquifers, Aquifers.

The measurement of aquifer parameters including permeability, storage and piezometric head in an observation borehole is an important part of the assessment of the aquifer as a resource. In order to investigate the aquifer parameters of a fissured layered sandstone aquifer, it is necessary to construct and test an abstraction borehole using laboratory, double packer, geophysical and pumping test techniques. Good correlation was found between the techniques when the aquifer was represented by a fissured layered aquifer with low permeability bands separating layers of higher permeability. The use of multiple peizometers proved to be the only way of obtaining sensible results for field pumping tests and has given storage coefficients for both the confined and unconfined sections of the aquifer. CONTAMINATION ANALYSIS - FLOW NETS AND THE MASS TRANSPORT EQUATION,
Florida Atlantic Univ., Boca Raton.
I. Watson.
Ground Water, Vol. 22, No. 1, p 31-37, January-February, 1984. 2 Fig, 1 Tab.

Descriptors: *Groundwater movement, *Flow pattern, *Path of pollutants, *Mass transport, Leachates, Groundwater hydrology, Permeability, Seepage, Groundwater pollution, Mathematical equations.

The introduction of newly-implemented regulations allows the hydrogeologist to participate in a more detailed way in the planning of waste disposal facilities. The level of hydrogeological input is a function of the nature and size of the project in question, since this, in turn, determines the budget available for investigation. A simple, analytical procedure for quantifying geohydrological data relating to waste site selection, groundwater contamination, and aquifer characteristics is presented. The analytical methodology outlined employs an extension of flow-net theory to determine seepage velocity and a derivation of the chemical mass transport equation to predict the attenuation of leachate constituents in the groundwater regime. The mathematical expressions derived take into account both transient and steady-state development of the plume, but are based on sufficient simplifying assumptions to facilitate convenient manipulation on a scientific calculator. The solutions obtained, although approximate, compare favorably with more costly computer-generated results. User application relates to the solution of first-order problems and in cases where a more sophisticated analysis is required, provides input for selecting the appropriate technique. (Wheatley-IVI)

REMOTE SENSING AND GEOPHYSICAL INVESTIGATIONS OF GLACIAL BURIED VALLEYS IN NORTHEASTERN KANSAS,
Kansas State Geological Survey, Lawrence.
J. E. Denne, H. L. Yarger, P. A. Macfarlane, R. W. Knapp, and M. A. Sophocleous.
Ground Water, Vol. 22, No. 1, p 56-65, January-February, 1984. 8 Fig, 17 Ref.

Descriptors: *Kansas, *Glacial aquifers, *Remote sensing, *Groundwater potential, Geophysics, Groundwater hydrology, Test wells, Seismic properties, Satellite technology.

Aquifers found in glacial buried valleys are a major source of good-quality ground water in northeastern Kansas. The extent and character of many of these deposits are not precisely known. Test drilling, Landsat imagery, shallow-earth temperature measurements, seismic refraction, surface electrical resistivity, and gravity data were used to evaluate two sites in Nemaha and Jefferson Counties. Tonal patterns on springtime Landsat imagery and winter/summer anomalies in shallow-earth temperatures were quick and inexpensive methods for locating some glacial buried aquifers and suggested areas for more intensive field studies. Reversed seismic refraction amd resistivity studies were generally reliable indicators of the presence or absence of glacial buried valleys, with most depth determinations being within 25% of test-drilling results. The effectiveness of expensive test-hole drilling was greatly increased by integrating remote sensing, shallow-earth temperature, seismic, and resistivity techniques in the two buried valley test areas. A gravity profile allowed precise definition of the extent of one of the channels after the other techniques had been used for general information. (Murphy-IVI)

DETERMINATION OF HORIZONTAL AQUIFER ANISOTROPY WITH THREE WELLS,
Arizona Univ., Tucson. Dept. of Hydrology and Water Resources.
S. P. Neuman, G. R. Walter, H. W. Bentley, J. J. Ward, and D. D. Gonzaliz.
Ground Water, Vol. 22, No. 1, p 66-72, January-February, 1984. 5 Fig, 1 Tab, 8 Ref. 2 Append.

Descriptors: *Anisotropy, *Aquifer testing, *Pumping tests, Confined aquifers, Field tests.

Existing methods for the determination of horizontal aquifer anisotropy by means of pumping tests require a minimum of four wells, one for water withdrawal and three for drawdown observations. This paper shows how the same methods can be used to determine anisotropy with as few as three wells, if at least two of them can be pumped in sequence. A field example is included. A method of analyzing data from more wells than the above minimum, by least squares, is also described. (Author's abstract)

GEOHYDROLOGY AND HYDROCHEMISTRY OF THE DAKOTA AQUIFER, CENTRAL UNITED STATES,
Kansas State Geological Survey, Lawrence.
R. B. Leonard, D. C. Signor, D. G. Jorgensen, and J. O. Helgesen.
Water Resources Bulletin, Vol. 19, No. 6, p 903-911, December, 1983. 10 Fig, 28 Ref.

Descriptors: *Geohydrology, *Water chemistry, *Dakota aquifer, Aquifers, Dissolved solids, Groundwater recharge, High Plains, Brines.

The Dakota aquifer, composed of the Dakota Sandstone and stratigraphically equivalent sandstone units of Cretaceous age, is the upper-most regional aquifer underlying the extensively developed High Plains aquifer of the midwestern United States. The concentration of dissolved solids in ground water of the Dakota aquifer ranges from less than 500 milligrams/liter in calcium bicarbonate type water in the eastern outcrop area to more than 100,000 milligrams/liter in sodium chloride type oilfield brine in the Denver Basin to the west. Preliminary maps showing the distribution of dissolved solids confirm the complex nature of the Dakota aquifer as inferred from stratigraphic and hydraulic evidence. Extensive vertical leakage through confining layers, local recharge at the truncated eastern boundary, and a barrier to recharge along the western edge of the Denver Basin are consistent with the distribution of hydraulic head and dissolved solids. (Author's abstract).

KRIGED ESTIMATES OF TRANSMISSIVITY IN THE MESILLA BOLSON, NEW MEXICO,
Greenhorne and O'Mara, Inc., Denver, CO.
M. R. Palumbo, and R. Khaleel.
Water Resources Bulletin, Vol. 19, No. 6, p 929-936, December, 1983. 7 Fig, 2 Tab, 18 Ref.

Descriptors: *Kriging, *Transmissivity, *Mesilla Bolson, *New Mexico, Santa Fe Aquifer, Mathematical studies, Analysis of variance, Aquifer characteristics.

Kriging utilizes a statistically based procedure of spatial interpolation that incorporates the spatial correlation structure of the phenomenon, and provides an error estimate. Kriging was applied to a total of 141 transmissivity values in an attempt to quantify the transmissivity distribution of the Santa Fe aquifer in Mesilla Bolson, New Mexico. The analysis produced contour maps of estimated transmissivity values and associated estimation variances. Through variogram analysis and fitting of an exponential variogram to 141 natural log of transmissivity (lnT) values, the range was 3 miles,

the average variance 2.74 (theta sub lnT-1.65) with a mean of 8.65. Kriged estimates were generally lower compared to estimates based on available transmissivity maps. (Murphy-IVI)

A SIMPLE ANALYTICAL SOLUTION FOR THE BOUSSINESQ ONE-DIMENSIONAL GROUNDWATER FLOW EQUATION,
Thessaloniki Univ., Salonika (Greece). Lab. of Hydraulics and Hydraulic Works.
P. K. Tolikas, E. G. Sidiropoulos, and C. D. Tzimopoulos.
Water Resources Research, Vol. 20, No. 1, p 24-28, January, 1984. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Groundwater movement, *Mathematical equations, *Boussinesq equation, Differential equations, Piezometric head, Groundwater recharge.

Boussinesq's equation describing groundwater flow is a nonlinear parabolic partial differential equation. An approximate analytical method was developed for the solution of the nonlinear one-dimensional Boussinesq equation. Uniform initial conditions and a step function increase of piezometric head on the boundary are assumed. The analysis, based on integral relations, reduces the solution of the differntial equation to a simple system of nonlineart algebraic equations, which can be solved by hand. The analysis makes use of basic characteristics of the solution that are derived directly from the differential equation. The existence of an inflection point is established and the determination of its position clarifies the behavior of the solution. The technique can also be applied to one-dimensional nonlinear diffusion problems. The method cannot be applied to the problem of dewatering, due to the fact that an inflection point does not appear in the piezometric head profile and thus the basic qualitative and quantitative criteria exploited in the construction of the approximate solution are not applicable. For the problem of recharge of an aquifer from a stream, the method provides a very simple algebraic formula for the computation of stored volume and piezometric head profile. (Moore-IVI)

FINITE-ELEMENT METHODS BASED ON A TRANSPORT VELOCITY REPRESENTATION FOR GROUNDWATER MOTION,
Dienst Grondwaterverkenning TNO, Delft (Netherlands).
W. Zijl.
Water Resources Research, Vol. 20, No. 1, p 137-145, January, 1984. 6 Fig, 16 Ref.

Descriptors: *Groundwater movement, *Velocity, Solute transport, Advection, Computer models, Simulation, Mathematical models, Pollutants, Heat.

Since the primary transport mechanism of pollutants and heat in a subsurface flow system is advection, accurate determination of the velocity of the carrier fluid percolating through the porous medium is extremely important. Computer-based groundwater motion simulators conventionally use pressure as the primary variable, and after the pressure field is calculated, the velocity is determined by numerical differentiation. This paper presents an approach to a direct numerical solution of the transport velocity field. Evidence is provided to show that it is advantageous to base a finite-element-oriented simulator on a transport velocity representation (TVR) of Darcy's law. The computer code then requires less storage and fewer arithmetic operations than a pressure representation (PR) version of the same code, provided that the same accuracy for the transport velocity is required in both cases. (Author's abstract)

THE VARIABILITY OF RECHARGE OF THE ENGLISH CHALK AQUIFER,
S. R. Wellings, and J. D. Cooper.
Agricultural Water Management, Vol. 6, No. 2/3, p 243-253, 1983. 6 Fig, 9 Ref.

Descriptors: *Aquifers, *Recharge, England, Chalk aquifer, Groundwater recharge, Groundwater management, Groundwater pollution, Nitrates.

The Chalk aquifer is the major water supply aquifer in England. Arable farming is the predominant land use over most of the outcrop area and nitrate pollution associated with this is causing problems. The fissure system provides a potential fast route for pollutants to reach the water table. The hydrological behavior of the upper 3 m of the Chalk profiles appear to depend on two properties: the thickness of soil cover or the depth of disturbance of the Chalk, which controls the water storage characteristics at high matric potentials; and the saturated matric conductivity of the Chalk, which determines the frequency with which the fissure system becomes water-filled. SEEPAGE FROM LAKE BURULLUS INTO THE RECLAIMED MANSOUR AND ZAWIA POLDER AREA,
Euroconsult, Arnhem (Netherlands).
J. H. Boumans, and A. M. Mashali.
Agricultural Water Management, Vol. 7, p 411-424, 1983. 4 Fig, 5 Tab, 5 Ref.

Descriptors: *Groundwater movement, *Seepage, *Mansour, *Zawia, *Egypt, *Land reclamation, *Saline water, Lake Burullus, Polders, Drainage effects, Water table, Saline soils.

In 1960, a part of Lake Burullus, situated west of the north-central part of the Nile Delta, along the Mediterranean, was diked in, which created the Zawia and Mansour polder area of 27,300 ha. Reclamation was not fully successful, however, and the agricultural land is still highly saline. The groundwater tables are still too high and the drainage should be intensified and deepened. The thickness, nature and permeability of the clay cap overlying the extended sand and gravel aquifer are such that there is little risk that seepage will increase greatly after lowering the water-tables in the polder area. Piezometer studies indicated that seepage rates under the present conditions are very limited, which implies that an increase after improved drainage would remain very restricted. These findings were confirmed by calculations of the seepage flow for present and future conditions. The calculated seepage increase and the total future seepage inflow reaching the polder are minor and practically neglible compared with the available drainage capacity. Rates five to ten times higher than those calculated could easily be handeled by the existing drainage system. (Moore-IVI)

DELAYED YIELD. AN EXACT QUASI-THREE DIMENSIONAL MODEL FOR FREE-AQUIFERS,
Universidad Nacional Autonoma de Mexico, Mexico City. Inst. de Investigacion en Matematicas Aplicadas y en Sistemas.
I. Herrera, and B. Chen.
Advances in Water Research, Vol. 6, No. 1, p 54-58, March, 1983. 2 Fig, 17 Ref.

Descriptors: *Aquifers, *Model studies, Mathematical equations, Boulton's theory, Surface flow, Waves, Delayed yield, Leaky aquifers.

A quasi-three-dimensional model of free surface flows is developed for free aquifers and waves. The zero-order approximation of this model yields Boulton's theory of delayed yield, elucidating in this manner the nature of the latter theory. The study demonstrated the linearized theory of free-aquifers to be exactly equivalent to an integrodifferential equation in which the partial derivatives involved are taken in the horizontal directions only and time. When a cosine transform is used in the vertical direction a system of equations is obtained. If N terms are taken in the cosine representation an exact theory is obtained, except for the fact that the kernel w is approximated by the kernel w sub N. The zero-order approximation yields Boulton's delayed yield equation. The approximated kernel w sub N converges rapidly to the exact kernel w. This implies that if only one term is taken, a theory in which w has been replaced by w sub 1 is obtained, but it is otherwise exact. Such approximation seems to be quite adequate for most practical applications. (Baker-IVI)

OPTIMUM MANAGEMENT OF A REGIONAL CONFINED AQUIFER,
Thessaloniki Univ., Salonika (Greece).
D. Tolikas, P. Latinopoulos, P. Tolikas, and J. Ganoulis.
Advances in Water Resources, Vol. 6, No. 2, p 66-70, June, 1983. 8 Fig, 5 Ref.

Descriptors: *Confined aquifers, *Groundwater management, Management, Ptolemais, Greece, Mathematical models, Model studies, Optimization, Sensitivity analysis.

A management study was conducted for an aquifer-well system located in the industrial area of Ptolemais, Greece. An analytical solution for the steady state problem is obtained and parametric calibration of the mathematical model simulating the aquifer-well system follows. Calculated numerical results are compared with existing field data. An optimization model is introduced and the maximum possible discharge of the aquifer under continuously increasing pumping rates is calculated. A sensitivity analysis for the maximum discharge conditions follows and the basic assumptions of the mathematical model are checked. Furthermore an analytical relationship is obtained which describes qualitatively the development of the aquifer under pumping rate conditions. In general terms, due to the high value of the transmissivity as well as the limited hydraulic continuity with the neighboring aquifers the slopes of the hydraulic head are small, while a small increase of the pumping rate creates a considerable lowering of the hydraulic head. Therefore the maximum pumping rate from the aquifer is rather small and severe problems will appear in the near future in the industries of the region. (Baker-IVI)

ON THE APPLICATION OF THE BOUNDARY LAYER APPROXIMATION FOR THE SIMULATION OF DENSITY STRATIFIED FLOWS IN AQUIFERS,
Florida Univ., Gainesville. Dept. of Civil Engineering.
H. Rubin.
Advances in Water Resources, Vol. 6, No. 2, p 96-105, June, 1983. 5 Fig, 24 Ref.

Descriptors: *Density stratification, *Groundwater movement, *Boundary layers, *Simulation, Solute transport, Mathematical models, Computers.

Stratification of the density in groundwater flow stems from the contact between water which contains minerals in low concentration with water containing a high concentration of minerals. The flow in such a flow field should be simulated by solving simultaneously the equations of continuity, motion and solute transport, because solute concentration affects the dynamics of the flow. Such an approach is generally associated with complicated calculations and numerical schemes subject to problems of convergence and stability, as the basic equations are highly nonlinear. This study applies the phenomenological boundary layer approximation, and suggests a reference to three different zones in the flow field: (a) fresh water zone, (b) transition zone, and (c) mineralized water zone. In zones (a) and (c) it is assumed that the potential flow theory can be applied. In zone (b) the flow is nonpotential but the basic similarity conditions typical to boundary layers exist. The approach suggested in this study simplifies the mathematical models that should be used for the flow field simulation. This approach is especially attractive in cases where the Dupuit approxmation is applicable. In such cases very often analytical solutions can be obtained for unidirectional flows. In cases that are too complicated for representation by analytical solutions, the method can be used for the creation of simplified numerical schemes. Various

examples in this study demonstrate the application of the method for various field problems associated with steady state as well as unsteady state conditions. The simplicity of the method makes it useful for variety of problems. It can be used even by small institutions and small consulting firms, who have usually access to minicomputers and microprocessors. (Author's abstract)

THERMOHALINE CONVECTION IN FLOWING GROUNDWATER,
Technion - Israel Inst. of Tech., Haifa. Faculty of Civil Engineering.
H. Rubin, and C. Roth.
Advances in Water Resources, Vol. 6, p 146-156, September, 1983. 10 Fig, 6 Ref.

Descriptors: *Geothermal studies, *Groundwater movement, *Convection, *Salinity, Water temperature, Hydrodynamics, Dispersion, Aquifers, Hydraulic gradient.

Geothermal activity creates destabilizing temperature gradients which are significant in some aquifers. Usually, in such aquifers stabilizing salinity gradients also exist. The combination of temperature and salinity distribution in the aquifer may induce various types of hydrodynamic instabilities. The present article concerns the effect of anisotropic characteristics of the hydrodynamic dispersion on the growth of instabilities in the aquifer. Three different mechanisms may lead to instability of the flow field: (a) buoyancy forces may induce convection currents; if the difference between the convection velocity of salt, due to the hydraulic gradients, and that of heat is negligible, then this mechanism is generally most effective in planes parallel to the hydraulic velocity of the fluid (velocity due to the hydraulic gradient); (b) the difference between heat and salt effective diffusivities may lead to overstability; this mechanism is most effective in planes perpendicular to the hydraulic velocity; (c) the difference between the convection velocity of salt and that of heat may induce oscillations which are most effective in planes parallel to the hydraulic velocity. The growth of instabilities in an aquifer of unlimited length is different from their growth in an aquifer of limited length. In the latter thermohaline convection develops in planes perpendicular to the hydraulic velocity, whereas in the former it develops in planes forming an angle theta with the hydraulic gradient. The development of convection cells in the flow field is identified by numerical experiments. These experiments identify the convection cell length and the angle formed between the thermohaline convection plane and the hydraulic gradient. (Author's abstract)

CONVECTION IN AN AQUIFER ABOVE A LAYER OF HEATED IMPERMEABLE BEDROCK,
Auckland Univ. (New Zealand). Dept. of Theoretical and Applied Mechanics.
R. McKibbin.
New Zealand Journal of Science, Vol. 26, No. 1, p 49-64, 1983. 11 Fig, 2 Tab, 4 Ref.

Descriptors: *Geothermal studies, *Convection, *Geothermal aquifers, Heat flux, Boundary conditions, Bedrock, Temperature, Rayleigh number.

It has been proposed (Donaldson 1962 Journal of Geophysical Research 67:3449-3459) that a convective geothermal aquifer might overlie a layer of impermeable bedrock which conducts heat from the magmatic source below. Using perturbation analysis similar to that applied to general materially layered porous media by McKibbin & O'Sullivan (1980, 1981 Journal of Fluid Mechanics 96:375-393; 111:141-173), it is found that the presence of such a layer of bedrock markedly affects the convection patterns and heat flow compared with those which occur when the heat source is in direct contact with the convective system. Results show that the overall temperature difference between the heat source and the top surface required for instability is greater, while the heat flux is reduced for both impermeable and constant pressure upper boundary conditions. However the critical local (aquifer) Rayleigh number is decreased by the presence of the impermeable layer below. All effects are greater for the constant pressure top than for the impermeable top case. (Author's abstract)

2G. Water In Soils

WATER CONDITIONS IN CENTRAL CAUCASIAN SUBALPINE MEADOW,
Akademiya Nauk Gruzinskoi SSR, Tiflis. Inst. Botany.
C. Sh. Nakhutsrishvili, and Ch. Koerner.
Doklady Biological Sciences Vol. 267, No. 1-6, p 547-549, November-December, 1982. 3 Ref. Translated from Doklady Akademii Nauk SSSR, Vol. 267, No. 1, p 243-245, November, 1982.

Descriptors: *Meadows, *Water supply, Subalpine regions, Mountains, Central Caucasus Mountains, Soil water, Soil-water-plant relationships, Seasonal variations.

Studies were conducted in the region of Kazbegi to examine a Bromus variegatus-Agrostis planifolia-Trifolium ambiguum subalpine plant with special reference to water exhange of the soil, individual plants, and also the phytocenose as a whole. A high leaf water content, a negligible saturation deficit, and a high leaf water potential were noted throughout the growing season. In midsummer and during sunny weather and a 5-6 m/sec wind velocity, the transpiration of the studied plants was always higher in a pasture setting than in an ungrazed meadow setting. A tendency for a reduction in stomatal transpiration in the course of the day also was more strongly expressed in the hay meadow than in the pasture. The elevated water exchange in the pasture may be due to the lower diffusional and aerodynamic resistances of forb leaves and, also, the lower mean diffusional resistance of the phytocenose as a whole, conditioned by the sharp decline in grasses, which are predisposed to an elevated resistance. Grazing leads to a decline in the diversity of strategies in the phytocenose. (Baker-IVI)

QUANTITATIVE EXPRESSION OF SOIL-MOISTURE FUNCTION FOR REMOTE INDICATION,
Akademiya Nauk SSSR, Moscow. Nauchnyi Sovet po Neorganischeskoi Khimii.
B. V. Vinogradov.
Doklady Biological Sciences, Vol. 268, No. 1-6, p 16-18, January-February, 1983. 1 Fig, 4 Ref. Translated from Doklady Akademii Nauk SSR, Vol. 268, No. 4, p 1011-1013, February, 1983.

Descriptors: *Soil water, *Mathematical equations, *Remote sensing, Optical properties, Soil properties, Spectral intensity.

The quantitative expression of the relationship between remote optical characteristics and parameters of the natural environment is a major problem in the development of the fundamental bases of a space physical geography. Particularly difficult has been the mathematical description of the relationship between the coefficient of spectral intensity and soil moisture. Experimental investigations on loamy achromatic soils demonstrated the complex nonlinear characteristics of the relationship between the coefficient of spectral intensity (p) in the visible region of the spectrum and the moisture (w) of the 0-2 cm surface soil horizon. An equation is formulated which is the first to yield a quantitative expression of the p(w) function throughout the range of soil moisture and to reflect the phase composition of moisture in the soil. This permits broad extrapolation of remote soil-moisture indicators, minimization of preliminary sampling, and more rapid construction of p(w) calibration curves for changing natural and technical survey conditions. TRACING SUBSURFACE FLOW ON ROADCUTS ON STEEP, FORESTED SLOPES,
Intermountain Forest and Range Experiment Station, Ogden, UT.
W. F. Megahan, and J. L. Clayton.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1063-1067, November-December, 1983. 3 Fig, 2 Tab, 23 Ref.

Descriptors: *Storm seepage, *Permeability coefficient, *Roadcuts, Idaho, Sodium, Chlorides, Tracers, Saturated flow, Snowmelt, Macropores, Darcy flow.

In situ hydraulic conductivity was determined in a forested soil in the Idaho batholith by a tracer technique, and values were compared to hydraulic conductivity determined in the laboratory on cored samples. NaCl solutions were injected into piezometers placed in soil above a roadcut, and time for Na(+)or Cl(-) to appear in outlow at the roadcut during saturated subsurface flow generated from spring snowmelt was determined. Hydraulic conductivity values determined with the NaCl tracer averaged an order of magnitude greater than laboratory derived values. This is likely due to rapid flow in macropores formed from root channels or other biological activity that cannot be sampled by conventional coring and laboratory conductivity tests. Although the field tests indicated flow was clearly non homogeneous and anisotropic, an evaluation of the Reynold's number for the test conditions indicated Darcy flow was occurring. Sodium analysis provided a more distinct peak than Cl(-) when both concentrations were plotted vs. time. (Author's abstract)

A TRANSIENT METHOD FOR MEASURING SOIL WATER DIFFUSIVITY AND UNSATURATED HYDRAULIC CONDUCTIVITY,
Massey Univ., Palmerston North (New Zealand). Dept. of Soil Science.
D. R. Scotter, and B. E. Clothier.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1068-1072, November/December, 1983. 8 Fig, 13 Ref.

Descriptors: *Permeability coefficient, *Soil water, *Diffusivity, Matric potential transient, Soil wetting, Sorption, Desorption, Outflow.

The method for measuring the unsaturated diffusivity of soil involves measurement of the matric potential transient at one end of a soil sample following a step change in the potential at the other end. Small potential steps can be used in contrast with the analogous outflow methods, because the difficult task of accurately measuring small flow rates is obviated. The analysis used to obtain the diffusivity from the potential data relies mainly on the delay in the transient and does not depend critically on its shape, thus avoiding the other major problem associated with outflow methods. With the use of the graphs provided, data analysis is simple. Measurement of the total outflow induced by each potential step allows the hydraulic conductivity to be calculated from the diffusivity. Except during primary wetting, the method provides hydraulic conductivity - water content data for repacked sand that showed no hysteresis and agreed with data obtained using a steady-state method. The anomalous behavior observed during primary wetting was perhaps due to entrapped air making the retentivity relationship time dependent. When applied to field cores obtained from both relatively permeable and impermeable soil horizons, the method gave consistent hydraulic conductivity data for sorption and desorption and for replicate cores. STATISTICAL AND STOCHASTIC ANALYSES OF HYDRAULIC CONDUCTIVITY AND PARTICLE-SIZE IN A FLUVIAL SAND,
New Mexico Inst. of Mining and Technology, Socorro. Dept. of Geoscience.
E. Byers, and D. B. Stephens.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1072-1081, November/December, 1983.

10 Fig, 6 Tab, 23 Ref. OWRT project B-073-NMEX.

Descriptors: *Permeability coefficient, *Particle size, *Fluvial sands, Statistical analysis, Stochastic process, Soil water, Socorro, New Mexico.

An untilled medium-grained fluvial sand near Socorro, New Mexico, was sampled in horizontal and vertical transects to study the statistical and stochastic properties of particle-size parameters and saturated hydraulic conductivity. Hydraulic conductivity is log-normally distributed, whereas the 10% finer, median, and geometric mean particle sizes are normally distributed. The strongest correlation between hydraulic conductivity and particle-size distribution parameters is that of the log of hydraulic conductivity with the 10% finer particle size. Stochastic analyses using the autocorrelation function and spectrum indicate that the log of hydraulic conductivity and particle size are characterized by dissimilar spatial correlation structures in the verticle directions. In general, particle size is more structured, regular, and predictable and shows a close similarity with the stratigraphy as observed in the field. On the other hand, hydraulic conductivity in the vertical direction may best be modeled as a simple random variable. Variogram and kriging analyses indicate that both hydraulic conductivity and particle size are relatively isotropic in the horizontal plane and that marked similarities in spatial structure exist in this plane. The spatial distribution of saturated hydraulic conductivity in the horizontal plane is estimated reasonably well using the empirical relationship between particle size and conductivity along with the kriged estimates of the 10% finer particle size. COLOR PATTERNS AND WATER TABLE LEVELS IN SOME INDIANA SOILS,
Purdue Univ., Lafayette, IN.
D. P. Franzmeier, J. E. Yahner, G. C. Steinhardt, and H. R. Sinclair, Jr.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1196-1202, November/December, 1983. 3 Fig, 1 Tab, 20 Ref.

Descriptors: *Water table, *Soil types, *Indiana, *Soil color, Soil properties, Seasonal variation, Soil horizons, Soil saturation.

Since many uses of soil depend greatly on its moisture status, it is important to be able to predict the seasonal moisture pattern from soil morphology. The relationship of color patterns in the soil profile to the duration of saturation at various depths was investigated in some soils that are extensive in Indiana. In soils of sandy, coarse loamy, fine loamy, fine silty, and fine particle-size families, some general relationship was observed between water table depths and soil color patterns. Horizons that have dominantly gray (chroma $<$ or $=$ 2) color in the matrix or argillans are saturated much of the year. Horizons that have gray mottles, but are dominantly brown, are saturated a few months of the year if they are above the dominantly gray horizons, or are saturated most of the time if these horizons are below the dominantly gray horizon. Horizons that have dominant chroma of three in the matrix, mottles, or argillans are often saturated. Those that have dominant chroma of five or six and have no mottles with chroma of three or less are seldom or never saturated. Soils with three-chroma matrix, mottles or argillans are much wetter than they had been thought to be. These generalizations apply to many soils, but there are exceptions. Some soil colors may be inherited from the parent material and do not reflect soil wetness. (Moore-IVI)

EFFECT OF SOIL TEXTURE ON CRITICAL BULK DENSITIES FOR ROOT GROWTH,
Agricultural Research Service, Temple, TX. Grassland, Soil and Water Research Lab.
C. A. Jones.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1208-1211, November/December, 1983. 6 Fig, 1 Tab, 12 Ref.

Descriptors: *Soil water, *Soil density, *Roots, Growth, Clay, Silt, Fragipans, Soil texture.

Published and unpublished data from 10 studies were analyzed to determine the effects of soil texture on critical bulk densities for rooting at near-optimum soil water contents. Highly significant negative relationships were found between percentage clay or silt + clay and the bulk density at which rooting was at a maximum or the bulk density at which rooting was 0.2 of that maximum. Similar relationships were also found between percentage clay or silt + clay and (i) the bulk densities of soil layers classified as fragipans and (ii) the maximum bulk densities at which 'many' roots are reported in U.S. Soil Conservation Service pedon descriptions. Thus, soil texture can be used to estimate bulk densities of fragipans and critical bulk densities at which root growth is severely affected at near-optimal soil water contents. (Author's abstract)

IRRIGATION DECISIONS SIMPLIFIED WITH ELECTRONICS AND SOIL WATER SENSORS,
Agricultural Research Service, Kimberly, ID. Snake River Conservation Research Center.
J. W. Cary, and H. D. Fisher.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1219-1223, November/December, 1983. 6 Fig, 2 Tab, 5 Ref.

Descriptors: *Soil water, *Irrigation, *Wetting front, Drying rate, Water management, Microprocessors.

Two simple, inexpensive systems use electrical resistance measurements to provide useful, immediate information to assist decisions made on irrigation water application. In one system a microprocessor-based circuit coupled to a programmable calculator provides an on-site estimate of the time until the next irrigation will be required, based on field data and an operator-supplied parameter. The second system simply signals the arrival of the wetting front at any location in the soil by giving a visual indication, such as raising a mechanical flag. The microprocessor-based circuit measures and stores the resistance of four gypsum blocks once a day. The program in the portable calculator access this information and uses it to extrapolate the soil drying rate to predict the number of days until the next irrigation. By restricting the microprocessor circuit to data acquisition only and putting all number-handling routines into the calculator program, the cost and complexity of the microprocessor circuit is minimized, whereas maximizing the programming flexibility. This makes it feasible to install a number of these devices at different locations, all serviced by the same portable calculator. The water infiltration circuit intermittently scans eight sets of stainless steel electrodes to locate the soil wetting front during irrigation. When the resistance across the electrodes decreases, signaling the arrival of the front, the circuit trips a spring-loaded flag. This provides a visible sign that the wetting front has reached that point in the soil. The equipment worked well. When irrigation was required in six or fewer days, the microprocessor/calculator system made correct predictions 85% of the time. An example of how easily any irrigation scheduling method may be converted to the microprocessor/calculator system is presented. (Author's abstract)

AN EVALUATION OF THE SUCCESS OF MORECS, A METEOROLOGICAL MODEL, IN ESTIMATING SOIL MOISTURE DEFICITS,
Institute of Hydrology, Wallingford (England).
C. M. K. Gardner, and M. Field.
Agricultural Meteorology, Vol. 29, No. 4, p 269-284, 1983. 6 Fig, 5 Tab, 23 Ref.

Descriptors: *Soil moisture, *Estimating, MORECS, Rainfall, Evaporation, Evapotranspiration, Great Britain, Model studies, Water loss, Computers.

MORECS (Meteorological Office rainfall and evaporation calculation system) in its operational form uses daily meteorological data to produce weekly estimates of evapotranspiration, soil moisture deficit (SMD) and hydrologically effective rainfall for each square of a 40 x 40 km grid superimposed upon Great Britain. Grid square estimates of meteorological data are found using interpolation methods. A modified version of the Penman-Monteith equation is used to calculate evapotranspiration; a two-reservoir model is used to simulate the extraction of water in the SMD calculations. While the MORECS produces better SMD estimates for grass than earlier versions of the system, there is still a definite bias towards SMD overestimation in most years and underestimation in drought years. Better SMD estimations will arise only when good representative meteorological data is used. For the purpose of the hydrologist spatial detail is not normally needed and interest will be in the overall biases in MORECS SMD predictions explained here. However, for the agriculturalist who needs good SMD estimates for individual fields, errors of this type may be critical. (Baker-IVI)

SOIL WATER FLUX IN HUMID TROPICAL LATOSOLS UNDER COCONUT (COCOS NUCIFERA LINN.),
Center for Water Resources Development and Management, Calicut (India).
K. M. Varadan, and B. Raghunath.
Agricultural Meteorology, Vol. 30, No. 2, p 99-110, 1983. 4 Fig, 5 Tab, 7 Ref.

Descriptors: *Soil water, *Tropical regions, Coconuts, Humidity, Climates, Water supply, Kerala.

In the management of available water resources the necessity for estimation of seasonal variation in soil moisture storage will go a long way in proper planning for irrigation. For successful plant growth, the water supply should meet demand. The problem is that the evaporative demand of the atmosphere is continuous whereas the supply of water by natural precipitation is only occasional and irregular. Soil moisture storage depends on the soil water diffusivity, the cumulative infiltration and the distance that water penetrates the soil. Field observations were compared with those computed from meteorological variables. The field observations of soil moisture flux agree closely with computed values for wet periods of the year, while they differ significantly for dry periods. Modification was attempted for the climatic computation by taking into account a lower moisture depletion rate for the dry period. Soil moisture indices have been calculated for the study period as a basis for irrigation management. The observed soil moisture varies from 17.0 to 25.0 cm and 6.8 to 12.8 cm per 75 cm depth of soil profile for wet and dry periods, respectively. (Baker-IVI)

RELATIONSHIP OF IRRIGATION WATER SALINITY AND SOIL WATER SALINITY,
T. L. Prichard, J. L. Meyer, G. J. Hoffman, F. R. Kegel, and R. Roberts.
California Agriculture, Vol. 37, No. 7 and 8, July-August, 1983. 3 Fig.

Descriptors: *Soil water, *Salinity, Leaching, Irrigation water, Deltas, Conductivity, Water table, Irrigation effects.

Irrigation water quality has a dominant influence on soil salinity, but winter rainfall, soil properties, leaching practices, irrigation techniques, and the elevation and salt concentration of a water table can significantly affect the relationship. The relation between the electrical conductivity of the irrigation water and the average electrical conductivity of soil water in the root zone for a subirrigated portion of the experimental field is given.

Above average rainfall and maintaining the water table about 1 meter below the surface effectively leached the upper soil profile. Under present conditions of low salinity in the irrigation water and with normal winter rainfall, soil salinity is about 8 times greater than the salinity of the irrigation water. As the salinity of the irrigation water increases, however, the factor 8 becomes substantially smaller. (Baker-IVI)

WATER RETENTION EQUATIONS AND THEIR RELATIONSHIP TO SOIL ORGANIC MATTER AND PARTICLE SIZE DISTRIBUTION FOR DISTURBED SAMPLES,
Department of Agriculture, Ottawa (Ontario). Land Resource Research Inst.
R. de Jong, C. A. Campbell, and W. Nicholaichuk.
Canadian Journal of Soil Science, Vol. 63, No. 2, p. 291-302, May, 1983. 4 Fig, 8 Tab, 20 Ref.

Descriptors: *Soil properties, *Organic matter, Water retention, Soil texture, Mathematical equations, Saskatchewan, Soil water.

Soil water retention curves are needed by many researchers in order to describe the availability of soil water to plants and to model the movement of water and salts in unsaturated soils. Functional relationships between soil water content and water suction were examined and related to textural and organic carbon content data. Soil water retention curves between 5 and 10,000 kPa were determined on disturbed samples of 18 soils representing various soil Great Groups in the Canadian prairies. The empirical two-straight-line model was the most suitable to relate soil water content to water suction. A very precise set of equations was developed for the samples chosen. Soil texture appeared to be the main soil property influencing the water retention curves of disturbed mineral soils. Organic matter increased the water content at which a break in the retention curve occurs, but had little effect on the rate of release of water or the soil suction at which the water became more difficultly desorbed. Water retention parameters calculated from particle size distribution and oganic carbon content data allow for general approximations of the relationship between soil water content and water suction. INTERMITTENT INFILTRATION AND EVAPORATION FROM SOIL COLUMNS,
Saskatchewan Univ., Saskatoon. Dept. of Soil Science.
M. A. Mustafa, R. De Jong, H. N. Hayhoe, and G. C. Topp.
Canadian Journal of Soil Science, Vol. 63, No. 2, p 303-314, May, 1983. 6 Fig, 3 Tab, 24 Ref.

Descriptors: *Soil water, *Infiltration, *Evaporation, Soil columns, Model studies, Richards' equation, Mathematical equations, Soil texture.

Large tracts of land in the arid and semi-arid regions of Sudan consist of salt-affected heavy clay montmorillonitic soils. Conventional reclamation procedures, including leaching and subsequent drainage, are not feasible because of the low hydraulic conductivity of these soils. Varying total amounts of water (160 and 320 mm) were infiltrated into 60-cm columns of air-dry saline sodic clay soil. The intervals between irrigation applications were varied from 5 to 20 days. The soil columns were subjected to a potential evaporation rate of 4.8 mm/day in a growth room. The cumulative evaporation followed a square root of time response, similar to that found by others for nonsaline soils of coarser texture. The percentage of water lost by evaporation was less for the high application rate treatments as compared to the low applicaton rate ones. Provided that more than 40 mm water were added, modelled estimates of evaporation were acceptable when predicted by the analytical solution of the Richards' equation. The versatile soil moisture budget model gave adequate predictions of evaporation and water content profiles, provided a field capacity measurement was taken. (Baker-IVI)

SOIL WATER DESORPTION CURVES ESTIMATED FROM LIMITED DATA,
Department of Agriculture, Ottawa (Ontario). Land Resource Research Inst.
R. de Jong.
Canadian Journal of Soil Science, Vol. 63, No. 4, p 697-703, November, 1983. 2 Fig, 3 Tab, 16 Ref.

Descriptors: *Soil water, *Desorption, Estimating, Mathematical equations, Canada, Soil properties.

Measuring soil water desorption curves is time consuming, tedious and expensive. The soil water desorption curve, modeled as a power curve, can be approximated from a limited number of measured water contents at specific tensions. Applicability of the model was tested on 90 soils. By forcing the soil water desorption curve through different measured water contents at various tensions, and by modifying different parameters, both the shape and the position of the curve could be altered considerably. Measurements at the two extremes were the most important, if only two water contents were measured. The best results were obtained when the curve was fitted through three measured water contents, respectively, at saturation, at an intermediate (5.0-35.0 kPa) tension, and at a high tension (1500.0 kPa). TILLAGE AND CULTURAL MANAGEMENT OF IRRIGATED POTATOES,
Iowa State Univ., Ames. Dept. of Agronomy.
D. R. Buxton, and J. C. Zalewski.
Agronomy Journal, Vol. 75, No. 2, p 219-225, March-April, 1983. 4 Fig, 5 Tab, 23 Ref.

Descriptors: *Tillage, *Cultural management, *Irrigation, *Potatoes, Soil compaction, Irrigation effects, Soil organic matter, Soil texture, Infiltration rate, Soil-water-plant relationships.

Many intensively row-cropped, irrigated soils are compacted and have slow water infiltration rates. Evaluating the relationship among soil compaction, water infiltration rates, and potato (Solanum tuberosum L.) yield and quality will help determine the influence of tillage and other practices on soil compaction, water infiltration rates, and potato response. Twenty-two commercial, irrigated potato fields were monitored and several tillage practices evaluated on soils from seven great groups. Soil compaction was evaluated by measuring penetrometer resistance. Although penetrometer resistance and water infiltration rates showed a large amount of variation in the 22 fields, they were not significantly correlated with each other. The correlation coefficient between penetrometer resistance 0.2 m below furrows and tuber yield was -0.38. Water infiltration rate was not associated with tuber yield nor quality. In the 18 fields with less than 600 g/kg sand, soil texture had little association with water infiltration rates, however, soil organic matter greater than 12 g/kg was positively associated with water infiltration rates. In the 22 fields, number of years between successive potato crops accounted for 33% of the variation in tuber yield with greatest yields when at least 4 years occurred between potato crops. In replicated tillage experiments, chiseling reduced penetrometer resistance to a deeper depth than moldboard plowing. Chiseling did not result in greater water infiltration rates, tuber yield, nor tuber quality than plowing. Chiseling and plowing in combination showed no advantage over either practice alone. Additionally, chiseling bed centers showed no yield advantage over an unchiseled check in fields that were previously plowed even though penetrometer resistance was reduced by chiseling. This study indicates that with proper irrigation management some deep tillage operations can be eliminated by many growers. (Murphy-IVI)

NUMERICAL ANALYSIS OF SOIL WATER MOVEMENT UNDER CONDITIONS OF RAPID INTERMITTENCY OF WATER APPLICATION,
Banaras Hindu Univ., Varanasi (India). Dept. of Geophysics.
M. Banerjee, and K. K. Watson.
Water Resources Research, Vol. 20, No. 1, p 119-125, January, 1984. 15 Fig, 6 Ref.

Descriptors: *Hysteresis, *Soil water, *Irrigation practices, Root zone, Wetting front, Sand, Permeability coefficient, Sprinkler irrigation, Infiltration, Timing.

When a sand material is subjected to a series of intermittent infiltration-redistribution cycles the hysteresis-affected material is limited to the surface horizons. Below this region, a zone of porous material exhibiting uniform water content and pressure head values develops. This zone is bounded at its lower end by the wet front and gradually lengthens as the cyclic wetting pattern continues. The development of the stable zone provides the basis for a simple in situ means of determining the hydraulic conductivity - water content relationship. The significance of the analysis in relation to sprinkler irrigation practice in regions of limited water supply is apparent. This is particularly the case where a fixed sprinkler system exists. If a control unit is introduced into the system, allowing the pulsed application of water, it is possible to control the rate of arrival of water to the root zone and generally balance this against the evapotranspiration demands of the system. Such a procedure would minimize drainage through the root zone to the lower soil horizons. (Moore-IVI)

EFFECT OF MIXED CATION SOLUTIONS ON HYDRAULIC SOIL PROPERTIES,
Haryana Agricultural Univ., Hissar (India). Dept. of Soils.
R. S. Siyag, R. Pal, S. R. Poonia, and T. C. Baruah.
Agricultural Water Management, Vol. 6, No. 1, p 15-25, 1983. 8 Fig, 4 Tab, 15 Ref.

Descriptors: *Permeability coefficient, *Soil water, *Diffusivity, Saturated flow, Unsaturated flow, Electrolytes, Sodium adsorption ratio, Clay loam, Sandy loam, Pore size.

Hydraulic conductivity (K) and soil water diffusivity (D) characterizing water flow under saturated and unsaturated conditions, respectively, were determined for a sandy loam and a clay loam soil, using water with different combinations of total electrolyte concentrations, C (i.e., 20, 40, 80, 125 and 250 meq/l) and sodium adsorption ratios (SAR). Both K and D increased with C and decrease with SAR. In low sodium adsorption ratio ranges (i.e., up to 20) the requirement of electrolyte concentration to maintain relative hydraulic conductivity = 0.5 was relatively more for sandy loam than for clay loam soil. However, the trend for electrolyte concentration requirements for the two soils was reversed at high sodium adsorption ratios (i.e. > 20). A spline function was used to draw the best fitting line through the data points of horizontal adsorption experiments. The reduction in K of these soils in relation to SAR is attributed to swelling, dispersion and migration of clay particles which result in the reorientation of soil particles and consequently affect the pore size distribution. Both swelling and movement of clay particles cause blocking of water conducting pores and hence a decrease in K. (Moore-IVI)

FUNCTIONING OF MOLE DRAINS IN CLAY SOIL,
Agricultural Research Council, Wantage (England). Letcombe Lab.
M. J. Goss, G. L. Harris, and K. R. Howse.
Agricultural Water Management, Vol. 6, No. 1, p 27-30, 1984. 1 Fig, 6 Ref.

Descriptors: *Subsoil drains, *Water table fluctuations, Drainage, Rainstorms, Clays, Soil properties,

Fissures, Mole drains, Water management, Model studies.

Observations of water-table fluctuation and drainflow are reported from a field experiment on a heavy clay soil with replicated 'mole-drained' and undrained plots. During a particular rainfall event the deep drains were the principal collectors yielding 86% of drainage water on the drained plots. Interflow was the most important collector for the undrained plots yielding 76% of drainage water. A direct comparison was made of the flow from the mole drains with the flow from the topsoil without interaction. The depth to the water table below the soil surface was least at the same time for both treatments and more than 1 hr later than the peak flow from the drains or collectors. The time of peak drainflow was the same on the drained and undrained plots, suggesting that flow into the drains was largely influenced by movement in the topsoil. The principal route of water from the soil surface to the mole drains was not uniformly through the subsoil, but rather via large fissures linking the topsoil with the mole channel. In the drained plots the water-table fluctuated within the subsoil which had only a small volume of drainable pores at each depth. Thus removal by the closely spaced mole drains of only a small volume of water caused a large fall in the water table. In contrast in the undrained plots the water flowed largely in the more porous Ap horizon for most of the recession and so required a much larger volume to be removed for a similar fall in the water table. USE OF SOIL SURVEY DATA TO SELECT MEASUREMENT TECHNIQUES FOR HYDRAULIC CONDUCTIVITY,
J. Bouma.
Agricultural Water Management, Vol. 6, No. 2/3, p 177-190, 1983. 4 Fig, 4 Tab, 29 Ref.

Descriptors: *Permeability coefficient, *Soil properties, Soil water, Physical properties, Macropores, Saturated soils, Unsaturated soils, Soil types.

The selection of proper physical-measurement techniques as a function of different soil and site conditions is examined. The conditions are such as can be derived from soil-survey information. A comparison is offered of different operational aspects of measurement methods. Some arbitrarily selected examples are presented to illustrate the importance of soil and site conditions for selecting methods for measuring hydraulic conductivity. Sample size, soil swelling, occurrence of macropores in both saturated and unsaturated soils, and soil profiles are considered. (Baker-IVI)

A HEURISTIC MODEL OF SOIL WATER REGIMES IN CLAY SOILS IN THE PRESENCE OF MOLE DRAINAGE,
A. C. Armstrong.
Agricultural Water Management, Vol. 6, No. 2/3, p 191-201, 1983. 3 Fig, 1 Tab, 9 Ref.

Descriptors: *Soil water, *Drains, Mole drains, Drainage, Soil properties, Clays, Soil types, Heuristic model, Model studies.

Soil water regimes are considered as they affect agriculture either through affects on plant growth or on the farmer's ability to use the land. A clay soil is considered as a two phase system, in which there is rapid movement within a system of structural passages (macropores) which have a relatively low volume in the soil mass but a high conductivity, and a far more extensive but much less conductive system of micropores. The proposed model is intended as a heuristic device to explore the possibility of a two-phase model for predicting soil water regimes. Its criterion for success is the matching of observed and pedicted water table behavior and not the physical explanation it offers. The model divides into four major components: infiltration, water table modelling, the coupling model and surface storage. Preliminary results are offered using rainfall inputs for Okehampton in Devon running the model for a 200 day period from October to March using daily rainfall values. While a significant portion of the input to the micropore system is by infiltration from the macropores, this component does not dominate the response since it is only about 25% of the total input. A significant factor in maintaining high water tables very near the surface is the carry-over effect afforded by the storage of water on the surface. The implication must be that effective surface drainage, by removing this store, has a beneficial effect. (Baker-IVI)

REGIONAL FIELD STUDY OF THE SPATIAL VARIABILITY OF SELECTED SOIL PHYSICAL PROPERTIES,
A. G. Hornsby, J. M. Davidson, D. K. Cassel, and R. R. Bruce.
Agricultural Water Management, Vol. 6, No. 2/3, p 269-276, 1983. 2 Fig, 3 Tab, 11 Ref.

Descriptors: *Soil properties, *Spatial distribution, Physical properties, Soil water, Water management, Farming.

With increased interest in managing soil water for crop production in areas which rely primarily on rainfall to meet crop demands, a greater need exists to understand the spatial and temporal variability of soil hydraulic properties. This collection of field and lab data using standardized methods permits critical analysis of the appropriateness of the methods for a particular use and reveals those situations where the methods fail. The instantaneous profile method or the plane of zero flux method for determining in situ unsaturated hydraulic conductivity of field soils works well for most of the soil series examined in this study. Some difficulty was found in establishing a water saturated soil profile at some sites due to macropores which short-circuited the water through the profile and prevented the ponding process from thoroughly wetting the entire profile. A problem encountered at some sites was the inability to saturate the lower horizons which were located below a less permeable horizon and which usually had a higher clay content. Swelling of the undisturbed soil cores used to measure bulk density and the soil-water retention curves contributed to measurement errors of these two parameters. (Baker-IVI)

PROBABILITY OF WATERLOGGING ESTIMATED FROM HISTORICAL RAINFALL RECORDS,
Ministry of Agriculture, Fisheries and Food, Cambridge (England). Field Drainage Experiment Unit.
C. W. Dennis, and J. Grindley.
Agricultural Water Management, Vol. 6, No. 4, p 397-401, 1983. 1 Fig, 2 Tab, 7 Ref.

Descriptors: *Waterlogging, *Rainfall, *Probability, Soil water, Drainage, Cambridge, England.

The usual method of operating the lysimeter facility at the Letcombe Laboratory (Great Britain) has been to apply large amounts of artificial rainfall over a short period of time in order to achieve the onset of sharp, well defined waterlogging events. This has presented the problem of assessing the likelihood in the field of the various simulated rainfall applications which the experimental program has used. The probability of waterlogging occurring on a given date may be calculated from meteorological records, provided that certain soil properties are known. In essence the method involves ascertaining the return period for a given fraction (either greater or smaller than unity) of the average rainfall in the period between arrival at or departure from field capacity and the particular date of interest. Due to the normal presence of some sort of drainage, the values obtained may be regarded as minima. The area around Cambridge, England is used in a demonstration of the method. (Moore-IVI)

TRANSPORT OF WATER IN FROZEN SOIL. II. EFFECTS OF ICE ON THE TRANSPORT OF WATER UNDER ISOTHERMAL CONDITIONS,
Cold Regions Research and Engineering Lab., Hanover, NH.
Y. Nakano, A. Tice, J. Oliphant, and T. Jenkins.
Advances in Water Resources, Vol. 6, No. 1, p 15-26, March, 1983. 11 Fig, 2 Tab, 16 Ref.

Descriptors: *Water transport, *Soil water, *Frozen ground, Ice, Mathematical analysis, Soil properties, Clays.

It is known that water in frozen soil generally exists in three phases: vapor, liquid (absorbed water) and ice. In liquid phase water in frozen soil is often referred to as unfrozen water. The unfrozen water content mainly depends on the soil type and temperature although unfrozen water versus temperature curves usually exhibit minor hysteresis depending on cooling and warming cycles. Experimental results obtained using Morin clay at minus 1.0 degrees C, showed that the presence of ice significantly affects the transport of water. A strong correlation exists between the flux of water and the gradient of total water content. A theoretical analysis of the experimental results and a dis-

cussion of a possible mechanism for water transport in frozen soil are presented. (Baker-IVI)

THE SOIL-MOISTURE ZONE IN A PHYSICALLY-BASED HYDROLOGIC MODEL,
Waterloopkundig Lab., Delft (Netherlands).
B. H. Gilding.
Advances in Water Resources, Vol. 6, No. 1, p 36-43, March, 1983. 6 Fig, 24 Ref.

Descriptors: *Hydrologic models, *Soil water, *Aeration zone, Mathematical models, Unsaturated flow, Soil-water-plant relationships.

An approach to modelling the unsaturated soil-moisture zone in the framework of an integrated physically-based hydrologic response model was developed. The subsurface flow regime may be viewed as two separate entities: a saturated flow system which may be modelled by standard two-dimensional regional techniques, and a single overlying unsaturated zone in which the flow is essentially vertical. Coupling takes place via the definition of saturation at the lower boundary of the unsaturated zone, and via a conservative water balance. Attention is focused on the computational procedure for the unsaturated zone as a self-contained module. The major difficulties are the definition of the interface between the saturated and unsaturated zones, the nonlinear character of the equation used to describe unsaturated flow, the inclusion of realistic atmospheric boundary conditions, and, the interaction between water uptake by plants and available soil-moisture. The complete numerical technique is non-iterative, and is based upon the use of a predictor and corrector at each time-step. The computational procedure yields the soil-moisture distribution, actual infiltration or surface evaporation, and actual water uptake by plants as functions of time with specified initial and potential values as input. SOIL MORPHOLOGY AND WATER REGIMES IN 3 RECENT ALLUVIAL SOILS ON THE TAIERI PLAINS, SOUTH ISLAND, NEW ZEALAND,
Department of Scientific and Industrial Research, Dunedin (New Zealand). Soil Bureau.
S. M. Smith, and F. G. Beecroft.
New Zealand Journal of Science, Vol. 26, No. 3, p 403-411, 1983. 2 Fig, 3 Tab, 18 Ref, 1 Append.

Descriptors: *Soil water, *Soil morphology, *South Island, *New Zealand, Soil water table, Seasonal variation, Matrix color.

An assessment of soil morphology and water regimes of 3 recent alluvial soils on the Taieri Plains, South Island, New Zealand, is described. The pattern of soil water table fluctuations follows a yearly sigmoidal cycle. With increased duration of saturation, mottles tend to decrease in size and abundance and have more diffuse boundaries. The matrix colors of the soil horizons, in conjunction with the nature of the mottles, broadly reflect the different moisture regimes at the 3 sites although the distinction between imperfectly and poorly drained soils is not clear. Moisture regimes as used by the Soil Survey of England and Wales successfully separated the soils into distinctive (quantified) classes. Soil Taxonomy separated the 2 wetter members of the sequence, but does not quantify the duration of saturation. Further research is needed to develop a system of soil moisture regime classification in New Zealand if soil survey interpretations are to be expanded. (Author's abstract)

THE NATURAL HISTORY OF A NEARCTIC TEMPORARY POND IN ONTARIO WITH REMARKS ON CONTINENTAL VARIATION IN SUCH HABITATS,
Toronto Unv. (Ontario). Div. of Life Sciences.
D. D. Williams.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 2, p 239-253, 1983. 5 Fig, 1 Tab, 21 Ref.

Descriptors: *Invertebrates, *Ponds, *Temporary ponds, Population dynamics, Seasonal variations, Ontario, British Columbia, Model studies, Fauna.

Physical, chemical and faunal characteristics of a temporary vernal pond in southern Ontario, Canada are given. As the pond water evaporated temperature and conductivity rose while pH varied. Ninety-eight taxa were identified which showed seasonal succession over the annual cycle of the pond. Five recognizably distinct faunal groups, based on time of appearance and period of activity, were apparent. Group 1 animals were found during the entire aquatic phase. Group 2 animals were active within days of the pond filling in the spring and completed their life cycle within 4-6 weeks. Group 3 animals appeared 2-5 weeks after filling and typically took 5 weeks to mature. Species in Group 4 were evident only 2-3 week before the pond dried up and exhibited rapid growth. Group 5 animals appeared in the dry phase and included primarily terrestrial and riparian species. Community composition is analyzed in terms of trophic status of each taxon. This indicates shifts which were appropriate for seasonal changes in the pond's potential food resources. The taxonomic composition of the spring time fauna of this pond was compared with that of a very similar pond 2,400 km to the west, on Vancouver Island, British Columbia. The number of species in each major taxon was frequently identical in the two ponds. In addition, the faunas had 23 genera and 6 species in common. These two faunas are compared with a predictive model of the fauna compliment of annual temporary pools. (Baker-IVI)

PELAGIC DIATOM POPULATIONS IN LENTIC FRESHWATER MICROCOSMS,
California Univ., Berkeley. Lawrence Berkeley Lab.
J. Harte, D. Levy, and J. T. Rees.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 2, p 255-267, 1983. 3 Fig, 5 Tab, 23 Ref.

Descriptors: *Diatoms, *Population dynamics, *Lentic environment, Phytoplankton, Comparison studies, Epilimnion.

Three experiments, involving simultaneous monitoring of selected biological and chemical parameters in 50 l laboratory microcosms and the epilimnia of their parent reservoirs, from the autumn of 1978 to the winter of 1980 (lasting 8-13 weeks), ascertained the degree of similarity between laboratory and field systems. Microcosm dynamics, specifically diatom dynamics, most closely paralleled that found in reservoirs during late spring and early summer, a time of thermal stratification. During winter months when thermal stratification was absent or less pronounced, microcosm diatom populations diverged significantly from reservoir populations within 24 days. Microcosm design and operating conditions have a major bearing on microcosm usefulness for environmental assessment. (Murphy-IVI)

PRODUCTION AND ECOLOGY OF BENTHIC CHIRONOMID LARVAE (DIPTERA) IN LAKE HAYES, NEW ZEALAND, A WARM-MONOMICTIC EUTROPHIC LAKE,
Otago Univ., Dunedin (New Zealand). Dept. of Zoology.
A. A. Graham, and C. W. Burns.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 3, p 351-377, 1983. 10 Fig, 11 Tab, 56 Ref.

Descriptors: *Chironomid larvae, *Lake Hayes, *New Zealand, *Eutrophic Lake, Midges, Population dynamics, Benthic fauna, Phytoplankton, Organic matter, Ecological distribution, Aquatic productivity.

The benthic fauna of eutrophic lakes is usually dominated by chironomid larvae which, by their burrowing, respiration and excretion, may aid nutrient cycling in lakes and are also important as fish food. From December 1973 to March 1975 the mean annual production of the two dominant species, Chironomus zealandicus and Chironomus sp. a, was 29.2 g/sq m dry weight which is approximately 4.3% of the average annual phytoplankton production in the lake. A high annual P/B ratio of 18.5 is consistent with the multivoltine life cycle of C. zealandicus. Larval chironomid production in the second summer when Anabaena blooms were absent was only one quarter of that in the first summer and is consistent with the hypothesis that the production of benthic chironomids in Lake Hayes is closely linked to that of the phytoplankton through the sedimentation of autochthonous organic matter. ESTIMATES OF MICROBIAL POPULATIONS INVOLVED IN THE N CYCLE AND THEIR ACTIVITY IN WATER AND SEDIMENTS OF FISH FARMING PONDS UNDER MONO- AND POLYCULTURE SYSTEMS IN INDIA,
Kalyani Univ. (India). Dept. of Zoology.
B. B. Jana, and S. K. Roy.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 4, p 581-590, 1983. 6 Fig, 22 Ref. Indian Council of Agricultural Research grant 11(8)-76-ASR(I).

Descriptors: *Bacteria, *Population density, *Nitrogen cycle, *Fish farming, *Fish ponds, *Monoculture, *Polyculture, Ammonification, Nitrification.

Spatial differences in the microbial density of ammonifying, protein mineralizing, nitrogen fixing and nitrifying bacteria, and the rates of ammonification and nitrification (natural and potential) in water and sediments of four fish ponds used for traditional, mono- and polyculture systems of fish farming were related to the fish culturing practices adopted. The seasonal variation of ammonifying bacteria was positively correlated with the NH4-N level in the water. The natural and potential capacity to generate both nitrite and nitrate in these water bodies was strongly correlated with the concentrations of the different forms of inorganic nitrogen present. The rates of NO2-N and NO3-N formation occurring in these fish ponds were directly proportional to the amount of dissolved oxygen and pH of the environment, respectively. (Murphy-IVI)

A STUDY ON THE MACRO-ZOOBENTHOS AND THE PHYSICO-CHEMICAL CHARACTERISTICS OF THE BOTTOM OF BAKHIRA LAKE, UTTAR PRADESH, INDIA,
Gorakhpur Univ. (India). Dept. of Zoology.
K. Pandey, R. Shyam, S. Prasad, and H. S. Chaudhry.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 4, p 591-597, 1983. 2 Fig, 2 Tab, 22 Ref.

Descriptors: *Benthic fauna, *Physicochemical properties, *Bottom sampling, *Bakhira Lake, Population dynamics, Bottom water.

Bakhira Lake is the largest man-made lake of Eastern Uttar Pradesh. It is utilized for Boro (coarse paddy) cultivation, irrigation and fishing by poor village farmers. The lake is a combination of ten tals (large basins), and has no regular gradation in depth. Hydrographical features, qualitative and quantitative composition of the macro-zoobenthos, and the physico-chemical characteristics of the bottom water and sediment were studied from October 1976 to April 1977. Mollusks, insects, ostracods, annelids, nematodes and crusaceans are the main groups of zoobenthos. Mollusks together with insects dominate the benthic fauna (95.2 to 96.4% of numbers). The average density of macro-zoobenthos is more or less inversely related to the total alkalinity of the bottom water. Mollusks showed a positive correlation to temperature and a

negative correlation to insect density. (Murphy-IVI)

THE DISTRIBUTION OF DESMOGNATHINE LARVAE (AMPHIBIA: PLETHODONTIDAE) IN COAL SURFACE MINE IMPACTED STREAMS OF THE CUMBERLAND PLATEAU, USA,
Tulsa Univ., OK. Faculty of Natural Sciences.
J. A. Gore.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 13-23, March, 1983. 3 Fig, 2 Tab, 32 Ref.

Descriptors: *Streams, *Acidity, *Benthic environment, Population dynamics, Water pollution effects, Mine drainage, Mine wastes, Iron pyrite, Metals, Turbidity, Shading, Light intensity, Vegetation effects.

Selected water quality parameters of streams in the Cumberland Plateau area of Kentucky, Tennessee, and Alabama and their relationship to the occurrence of desmognathine larvae are considered. Higher densities of larvae were found in streams with greater than 80% overhead vegetation (less than 20% direct insolation). These streams with high overhead vegetation, therefore shaded, values were also those of the lowest stream order and discharge. There were no trends observed with regard to temperature of the water and dissolved oxygen concentrations, which were near to saturation levels for all streams studied. (Baker-IVI)

THE DESMIDS AND PHYSICAL CHARACTERISTICS OF 100 LAKES IN NORTHEASTERN PENNSYLVANIA,
Wilkes Coll., Wilkes-Barre, PA.
C. B. Reif, B. B. Smith, and A. Case.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 25-36, March, 1983. 4 Tab, 40 Ref.

Descriptors: *Lakes, *Species diversity, *Acid rain, *Desmids, *Pennsylvania, Water pollution effects, Bear Creek, Acidity, Sodium, Potassium, Magnesium, Calcium, Conductivity.

Paired samples taken from 100 lakes during July of 1980 were examined for desmids and analyzed chemically. The lakes lie in an area roughly one hundred km by fifty km within northeastern Pennsylvania. Elevations above mean sea level range from 289 m to 624 m. Harveys Lake, with an area of 280 hectares, is the largest natural lake, by volume, in the state. Lakes Henry and Ladore also exceed 100 hectares but the other 97 were smaller. From each lake two samples were taken in the littoral zone close to vascular aquatic plants. Simple linear regression analyses comparing desmids with pH, conductivity, alkalinity, calcium, magnesium, sodium, and potassium indicated very little statistical correlation between numbers of species and any single chemical factor. Stepwise regression for pairs of chemical values produced highest R-square for pH and magnesium but not positively significant. (Baker-IVI)

FORAGE FISH ASSEMBLAGES IN THE BRAZOS RIVER UPSTREAM AND DOWNSTREAM FROM POSSUM KINGDOM RESERVOIR, TEXAS,
North Texas State Univ., Denton. Inst. of Applied Sciences.
K. A. Anderson, T. L. Beitinger, and E. G. Zimmerman.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 81-88, March, 1983. 1 Fig, 2 Tab, 16 Ref. OWRT grant (B-22-TEX).

Descriptors: *Forage Fishes, *Population dynamics, *Brazos River, *Possum Kingdom Reservoir, Fish populations, Ecosystems.

River impoundments can affect downstream biological communities by changing temperature regimes, flow rates, substrate, water quality and nutrient availability. Metabolism of dissolved substances in lentic waters can lead to reduced nutrient availability and changes in water solute concentrations in water discharged from reservoirs. The forage fish assemblages of the Brazos River was sampled at one location above and four locations below Possum Kingdom Reservoir each month for one year. A total of 13,936 individuals representing 18 species, 14 genera and five families were collected. Five of these species, Notropis stramineus, Notropis atherinoides, Hybognathus placitus, Hybopsis aestivalis and Cyprinodon rubrofluviatilis were found only upstream from Possum Kingdom Reservoir. Hybognatus placitus accounted for 45% of fish captured at the upstream site. In contrast, nine species were collected exclusively in the tailwaters, including Etheostoma spectabile, Percina sciera, Campostoma anomalum, Notropis venustus, Pimephales notatus, Labidesthes sicculus and Fundulus notatus. Only four species were obtained at all five stations -- Gambusia affinis, Menidia beryllina, Pimephales vigilax and Notropis lutrensis. N. lutrensis was the most common tailwater species equalling 87.9% of the total downstream catch. Median species diversity indices ranged from 0.129 to 0.451 for the five stations, with the highest value at the upstream station. Coefficients of biotic similarity ranged from 0.20 to 0.62, with the upstream station clearly being the most dissimilar. These findings are discussed relative to environmental effects of hypolimnetic release of reservoir waters. (Murphy-IVI)

CHANGES IN THE CHIRONOMID (DIPTERA: CHIRONOMIDAE) FAUNA OF LAUREL CREEK RESERVOIR, WATERLOO, ONTARIO,
Waterloo Univ. (Ontario). Dept. of Biology.
T. W. Sephton, B. A. Hicks, C. H. Fernando, and C. G. Paterson.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 89-102, March, 1983. 3 Fig, 5 Tab, 49 Ref. NSERC grants A-3478 and A-6299.

Descriptors: *Population dynamics, *Laurel Creek Reservoir, *Waterloo, *Ontario, *Chironomids, Reservoirs, Eutrophication, Trophic level, Dissolved oxygen.

Qualitative and quantitative changes in the chironomid fauna of Laurel Creek Reservoir are presented as they were determined over the 13 years of its existence. A substantial decrease is noted in the average numerical abundance from 1967 to 1968, from 6303/sq m to 3373/sq m, and it has remained stable since 1975 to 1980. Distinct changes were noted in the faunal numerical abundance, although the genera have remained the same. In 1967, the Chironomini comprised 95% of the total throughout the year. In 1968, the Chironomini dominated with 68%, the Tanytarsini increased to 24% and the Tanypodinae at 6% and Orthocladiinae at 2% remained low. In 1975 the Chironomini accounted for 72% and the Tanypodinae increased to 21%, the Tanytarsini decreased to 5%, and the Orthocladiinae remained low at 2%. By 1980 the Tanypodinae had become dominant at 60% while the Chironomini had become dominant at 60% while the Chironomini had decreased to 38%. The Tanytarsini and Orthocladiinae were insignificant at 1% each. The decreased standing stock and changes in the dominance hierarchy of the chironomid fauna are associated with changes in the trophic level of the substrate conditions and bottom oxygen levels of the reservoir. Laurel Creek Reservoir has not entered a state of advanced eutrophy. (Baker-IVI)

ALKALINITY, DISCHARGE, AVERAGE VELOCITY, AND INVERTEBRATE DRIFT CONCENTRATION IN SUBARCTIC ALASKAN STREAMS,
Alaska Univ., Fairbanks. Inst. of Water Resources.
J. D. LaPerriere.
Journal of Freshwater Ecology, Vol. 2, No. 2, p 141-151, July, 1983. 4 Fig, 1 Tab, 23 Ref.

Descriptors: *Invertebrates, *Streams, *Alaska, Alkalinity, Velocity, Sediment transport, Invertebrate drift, Insects, Flow discharge.

The associations of alkalinity, current and invertebrate drift among 13 streams were measured in subarctic Alaska. A significant positive correlation was noted between alkalinity and drift concentrations expressed as numbers per unit volume. Significant inverse relations were found between stream discharge and drift concentration expressed as either numbers or weight. This dilution was to be expected as stream wetted perimeter, the source of invertebrates to drift, increases as approximately the square root of the discharge. Multiple regression analysis also showed a positive relation between stream average velocity and drift concentrations. Invertebrate drift was seen, therefore, to be somewhat analogous to sediment transport in streams. Most of the drift samples were numerically dominated by Diptera. Ephemeroptera usually were next in numbers, and Trichoptera and Plecoptera alternated in being third most numerous. (Baker-IVI)

LIMNOLOGICAL FEATURES OF SOME NORTHWESTERN FLORIDA LAKES,
Florida Univ., Gainesville. Inst. of Food and Agricultural Sciences.
D. E. Canfield, Jr., M. J. Maceina, L. M. Hodgson, and K. A. Langeland.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 67-79, March, 1983. 2 Fig, 7 Tab, 34 Ref.

Descriptors: *Limnology, *Sandhill lakes, *Florida, Mirrow Lake, Lake McKenzie, Turkey Pen Pond, Compass Lake, Round Lake, Crystal Lake, Dunford Pond, Gap Pond, Merial Lake, Chlorophyll, Chemical analysis, Acidity, Water quality, Oligotrophic lakes.

A limnological survey was undertaken of some sandhill lakes in Florida to assess their present limnological conditions. Nine lakes in all were examined. Mean depth ranged from 6.3 to 27 m. Secchi disc values ranged from 3.2 to 8.1 m. Thermal stratification occurred in all lakes. Chemically the lakes were characterized as acidic, soft-water lakes of low mineral content. Average total phosphorus values ranged from 3.1 to 10 mg/cu m, and average chlorophyll a values ranged from 0.5 to 1.4 mg/cu m. These are among the most oligotrophic lakes in Florida. It is felt that anthropogenic activities have had very little influence on these present conditions. The Lakes studied were Compass Lake, Crystal Lake, Dunford Pond, Gap Pond, Lake McKenzie, Merial Lake, Mirrow Lake, Round Lake, and Turkey Pen Pond. (Baker-IVI)

NITROGEN FIXATION AND PHOSPHORUS TURNOVER IN A HYPERTROPHIC PRAIRIE LAKE,
National Water Research Inst., Burlington (Ontario). Aquatic Ecology Div.
B. G. Brownlee, and T. P. Murphy.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 1853-1860, November, 1983. 3 Fig, 5 Tab, 27 Ref.

Descriptors: *Nitrogen fixation, *Phosphorus removal, *Hypertrophic lakes, Carbonates, Ammonia, Nitrogen cycle, Algae, Aphanizomenon, Manitoba, Eutrophication, Prairies.

Nitrogen fixation by Aphanizomenon flos-aquae in a prairie lake in southwestern Manitoba was dependent on the light intensity and in situ oxygen concentrations. The mean molar ratio of acetylene reduction to nitrogen reduction was 5.8:1. High external ammonium concentrations did not appear to inhibit nitrogen fixation over the short term. Nitrogen fixation was not directly initiated by the bloom collapse. The sequence of ammonia volatilization and nitrogen fixation was triggered by the bloom collapse and the bloom collapse was caused by coprecipitation of orthophosphate with carbon-

ates. PO4 turnover was most rapid during periods when the lake was opalescent, presumable due to carbonate precipitation. (Murphy-IVI)

A NEW APPROACH TO ESTIMATING POPULATIONS BY THE REMOVAL METHOD,
Department of Fisheries and Oceans, Nanaimo (British Columbia). Pacific Biological Station.
J. Schnute.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 12, p 2153-2169, December, 1983. 2 Fig, 5 Tab, 17 Ref, 5 Append.

Descriptors: *Fish populations, *Model studies, Populations, Mathematical models, New Brunswick, Estimating.

This new approach to the use of removal data in estimating the size of a population of fish or other animals admits a variety of assumptions on how catchability varies among fishings including the assumption of constant catchability. The methods hinge on maximum likelihood estimation, and can be used both to decide objectively if the data justify rejecting constant catchability and to determine confidence intervals for the parameters. A new method of assigning confidence to the population estimate points out problems with methods currently available in the literature. The theory is applied both to data in historical literature and recent data from streams in New Brunswick, Canada, which demonstrate that constant catchability can frequently lead to serious errors in data interpretation. In some cases, the conclusion that the population size is well known may be blatantly false, and reasonable estimates may be impossible without further data. (Murphy-IVI)

A STOCHASTIC AGE-STRUCTURED POPULATION MODEL OF STRIPED BASS (MORONE SAXATILIS) IN THE POTOMAC RIVER,
Rockefeller Univ., New York.
J. E. Cohen, S. W. Christensen, and C. P. Goodyear.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 12, p 2170-2183, December, 1983. 1 Fig, 2 Tab, 37 Ref. NCF grant DEB80-11026, NIMH grant 5T32MH14581-06.

Descriptors: *Stochastic process, *Fish populations, *Bass, *Potomac River, Morone, Mathematical models, Fish management, Statistical analysis, Spawning.

Deterministic age-structured models of fish populations neglect apparently stochastic fluctuations in the catch per unit effort of yearlings and of adult fish. A model is needed for an age-structured population in which the survival and egg-laying are constant. For such a stochastic model, two measures of the long-term population growth rate are the average growth rate of the population size and the growth rate of the average population size. Both measures are computed analytically for a simplified model representing only eggs and reproductive adults. For a model of the striped bass population spawning in the Potomac River, both point and interval estimates of the growth rate of the average population size are computed. These models can be used as a framework for modeling stochastic variation of vital rates in real age-structured populations. (Murphy-IVI)

MODEL OF MISSISSIPPI RIVER POOL: DISSOLVED OXYGEN,
Rutgers - The State Univ., Piscataway, NJ. Dept. of Civil and Environmental Engineering.
A. C. Demetracopoulos, and H. G. Stefan.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1020-1034, October, 1983. 8 Fig, 33 Ref.

Descriptors: *Mathematical models, *Mississippi River pool, *Dissolved oxygen, Photosynthesis, Respiration, Biochemistry, Biomass, Hydrologic models, Hydraulic transportation.

Dissolved oxygen (DO) describes the general health of a water body and is a quality varible that reflects the capacity of the system to support a balanced aquatic habitat. Biochemical oxygen demanding material (BOD) suspended or dissolved in the water (including waste), oxygen demanding material on the river bottom (Sedimentary oxygen demand, SOD) and respiratory requirements of the phytoplankton are the primary sink terms utilizing DO in a natural water body. The source/sink terms are very important for dissolved oxygen under low summer flow conditions. A simulation of dissolved oxygen (DO) dynamics and of biomass is incorporated in a dynamic wind and gravity driven hydrologic transport model. Photosynthesis introduced a diurnal cycle on the dissolved oxygen concentration, wich was sometimes very noticeable and sometimes obscured by other physical and biochemical processes. (Murphy-IVI)

GAS-FILM COEFFICIENTS FOR STREAMS,
Geological Survey, NSTL Station, MS.
R. E. Rathbun, and D. Y. Tai.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1111-1127, October, 1983. 1 Fig, 2 Tab, 36 Ref.

Descriptors: *Gas-film coefficients, Streams, Mathematical equations, Prediction, Organic compounds, Organic loading, Volatilization, Fate of pollutants.

Understanding the volatilization process is necessary for predicting correctly the fate of many organic compounds in streams and rivers. The volatization is frequently described by the two-film model. The film coefficient is a function of windspeed and water temperature. The dependence of the coefficient on windspeed is determined from published information on the evaporation of water from a canal. The dependence of the coefficient on temperature is determined from laboratory studies on the evaporation of water. Procedures for adjusting the coefficients for different organic solutes are based on the molecular diffusion coefficient and the molecular weight. The molecular weight procedure is easiest to use because of the availability of molecular weights. However, the theoretical basis of the procedure is questionable. The diffusion coefficient procedure is supported by considerable data. Questions, however, remain regarding the exact dependence of the film coefficient on the diffusion coefficient. The diffusion coefficient procedure with a 0.68-power dependence should be used when precise estimate of the gas-film coefficient are needed and the molecular weight procedure be used when only approximate estimates are needed. RESERVOIR CIRCULATION PATTERNS AND WATER QUALITY,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
B. R. Kim, J. M. Higgins, and D. J. Bruggink.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1284-1293, December, 1983. 4 Fig, 1 Tab, 5 Ref.

Descriptors: *Reservoirs, *Water circulation, *Water quality, Model studies, Mathematical models, Hypolimnion, Metalimnion, Wastewater outfall, Wastewater dilution, Hydrodynamics, Hydrological regime.

A two-dimensional hydrodynamic-temperature model examines the similarities between circulation patterns and observed water quality phenomena in Cherokee Reservoir. A circulation pattern, involving reverse bottom flows which occurred during March through July, most likely influenced high fecal coliform concentrations in the water supply intake (located in the reservoir upstream of a wastewater outfall), depressed dissolved oxygen concentrations in the metalimnion and the development of dissolved oxygen depletion in the hypolimnion. The potential effects of reservoir circulation suggest that reservoir operations might be used as one means of influencing water quality profiles within the reservoir. (Murphy-IVI)

PHYTOPLANKTON MODELING IN THE EMBAYMENTS OF LAKES,
National Taiwan Univ., Taipei. Dept. of Civil Engineering.
J.-T. Kuo, and R. V. Thomann.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1311-1332, December, 1983. 11 Fig, 4 Tab, 29 Ref. EPA grant R803680030.

Descriptors: *Phytoplankton, *Mathematical models, *Lake embayments, Water quality, Finite element method, Comparison studies, Hydrodynamics, Water circulation, Rochester embayment, Lake Ontario.

A steady-state, finite-element lake circulation model generates mean circulation patterns in homogeneous lakes. This coupled model applied to Rochester Embayment, Lake Ontario during the nonstratification period and to Saginaw Bay, Lake Huron, has the advantage of reducing a considerable amount of computer time when compared to the use of a transient hydrodynamic model for water quality modeling. The model can calculate large-scale dispersion and turbulent exchange coefficients from detailed velocities calculated from the finer-scale lake circulation model around the coarser water quality segments. Water current outputs and constituent concentration are sensitive to the change of vertical eddy viscosity, drag coefficient on the water surface, and wind data for the circulation model. REAERATION AND VERTICAL DIFFUSION OF LAKE OXYGEN,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
W. J. Snodgrass.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1419-1423, December, 1983. 2 Tab, 15 Ref.

Descriptors: *Lakes, *Aeration, Oxygen, Diffusion, Mathematical study, Air-water interfaces, Dissolved oxygen.

The interaction between the reaeration coefficient of oxygen across the atmosphere-water interface, k (m/day), and the veritcal diffusivity coefficient in the surface waters of the lakes and reservoirs, D (sq m/day), may act as controllers upon the oxygen profile. Factors influencing the shape and sensitivity of oxygen profiles of epilimnetic waters analyzed quantitatively using steady-state models was prompted by discrepancies in the sensitivity of oxygen model predictions to variations in the reaeration coefficient. For example, an oxygen model is expected to be insensitive to a reaeration coefficient greater than 1 m/day if the vertical diffusivity coefficient is less than ca 1 sq m/day. The influence of other combinations of reaeration coefficient and vertical transport rate upon observed oxygen concentrations can be analyzed using models expressed. (Murphy-IVI)

USE OF TIME-SERIES ANALYSIS TO DEMONSTRATE ADVECTION RATES OF DIFFERENT VARIABLES IN A SMALL LAKE,
McMaster Univ., Hamilton (Ontario). Dept. of Biology.
A. M. Trimbee, and G. P. Harris.
Journal of Plankton Research, Vol. 5, No. 6, p 819-833, 1983. 11 Fig, 1 Tab, 28 Ref.

Descriptors: *Time series analysis, *Advection, *Multivariable analysis, Algal growth, Interfaces, Weather, Phosphorus, Guelph Lake.

In algal ecology, attempts to seek direct correlations between environmental factors and algal abundance at one point in time or space will fail if non-equilibrium conditions occur and time lags exist between the environmental change and the phytoplankton response. Time-series analysis of daily data from 3 stations in a small lake demonstrates the existence of strong horizontal advection within the basin at a time scale of 2-3 d and longer term periodicities (10-20 d) associated with the

passage of atmospheric weather systems. Fluctuations in integral SRP concentrations at station 1 (outflow end) consistently occurred 3 d later than at station 3 (inflow end). The algal biomass (chlorophyll a) at station 1 lagged that at station 3 by half a day. The time lag between station 1 and station 3 for Aphanizomenon flos-aquae was 7 d, whereas for Ceratium hirundinella station 1 led station 3 by 3 d indicating motion by the species in opposite directions. The distribution of the algal biomass in space and time was a composite of the individual species patterns. The periodicities in the average daily wind speed and water column stability were likely due to periods of vertical mixing. The use of chlorophyll as a measure of biomass hides much important information about the changing species composition of the assemblage. The characterization of these important mixing scales is a necessary preliminary step in understanding the phytoplankton dynamics of the system. (Murphy-IVI)

ROLE OF CURRENT ON THE DISTRIBUTION OF JUVENILE FISHES IN RESERVOIRS,
Akademiya Nauk SSSR, Borok. Inst. Biologii Vnutrennykh Vod.
V. K. Konobeeva.
Journal of Icthylogy, Vol. 23, No. 1, p 96-102, 1983. 2 Fig, 1 Tab, 21 Ref.

Descriptors: *Fish, *Reservoirs, *Water currents, Fish behavior, Rybinsk Reservoir, Ivan'kovo Reservoir, Velocity, Wind.

An attempt was made by labeling of the water masses and juvenile fishes and observations on their movement, to explain the role of current in the distribution of juvenile fishes in reservoirs using examples of Rybinsk and Ivan'kovo reservoirs. While many factors influenced the movement of young fish in the reservoirs, the water current was definitely the major one. Juvenile phytophilous fishes at early stages of development can be carried by the current from the spawning ground into the open part of the reservoir. Larvae at development stages Al-E move in the open part of the lake and canal type reservoirs strictly with the watermass. In Rybinsk Reservoir (lake type), the fingerlings (standard length from 42-120 m) may drift not only passively in the water column but can also resist the current and move in a different direction over large distances irrespective of the velocity and direction of the current. In Ivan'kovo Reservoir which is of the canal type, not only the larvae but also advanced juveniles of 63-75 mm move with the watermass. This is probably due to high current velocity and its constant direction. (Baker-IVI)

OOGENESIS OF THE RYBINSK RESERVOIR BREAM, ABRAMIS BRAMA (CYPRINIDAE),
Akademiya Nauk SSSR, Borok. Inst. Biologii Vnutrennykh Vod.
A. M. Andreyeva.
Journal of Icthyology, Vol. 23, No. 2, p 74-78, 1983. 2 Fig, 8 Ref.

Descriptors: *Fish, *Reservoirs, Rybinsk Reservoir, Bream, Temperature effects, Distribution, Population density.

The annual sexual cycle of the bream, Abramis brama, of Rybinsk Reservoir and the duration of the individual stages of gonad maturity in specimens from different arms of the reservoir may be due to different temperature regimes. The bream is a major commercial species in the reservoir. The differences discovered in the annual sexual cycle of bream females from the Volga arm on the one hand and from the Mologa and North Sheksna arms on the other are further evidence of the existence in a single body of water such as Rybinsk Reservoir, of local bream populations previously found by tagging studies. Times and places of spawning, due to a different geographic position and hydrologic conditions of the body of water, are mainly responsible for the isolation of populations, although for a large part of the year individual fish groupings may also occupy common foraging and possibly overwintering areas. THE INFLUENCE OF FLOW TURBULENCE ON FISH BEHAVIOR,
Akademiya Nauk SSSR, Moscow. Nauchnyi Sovet po Neorganischeskoi Khimii.
L. G. Shtaf, D. S. Pavlov, M. A. Skorobogatov, and A. Sh. Barekyan.
Journal of Icthyology, Vol. 23, No. 2, p 129-140, 1983. 6 Fig, 7 Tab, 9 Ref.

Descriptors: *Fish behavior, *Turbulence, Fish, Streamflow, Velocity, Water currents.

The flow of water, as the environment inhabited by fish, has a strong influence on their behavior. The fish select zones with a heightened degree of turbulence, on places of concentration, swimming capacity, compactness of schools of fish in currents with varying turbulence characteristics, and degree of orientation of fish at speeds close to threshold, depending on the flow movement regime. The duration of swimming of the roach depended on the degree of flow turbulence with the increase in the intensity of turbulence bringing about a decrease in turbulent flow. At speeds close to threshold, the degree of orientation of the fish depended on the conditions of flow movement. In turbulent flow the fish more readily orient in the direction of the velocity vector than in laminar flow. (Murphy-IVI)

TOXICITY OF CYANOBACTERIA IN DUTCH LAKES AND RESERVOIRS,
Utrecht Rijksuniversiteit (Netherlands). Dept. of Veterinary Pharmacology, Pharmacy and Toxicology.
P. Leeuwangh, F. I. Kappers, M. Dekker, and W. Koerselman.
Aquatic Toxicology, Vol. 4, No. 1, p 63-72, August, 1983. 1 Fig, 5 Tab, 16 Ref.

Descriptors: *Toxicity, *Cyanobacteria, *Lakes, *Reservoirs, Algal blooms, Scum, Hepatotoxins, Fast-death factor, Slow-death factor, Microcystis aeruginosa, Oscillatoria agardhii, Gloeotrichia echinulata.

Poisoning of livestock, pet animals, waterfowl and fish by waterblooms or scums of freshwater cyanobacteria has been reported in literature from 1878 onwards. Since then there have been numerous cases of toxic waterblooms leading to a considerable loss of animals in many countries around the world. The waterblooms and scums of Microcystis aeruginosa, Oscillatoria agardhii and Gloetrichia echinulata showed that M. aeruginosa hepatotoxin(s) were present in 9 out of 10 locations. By i.p. injection in mice the cyanobacterial endotoxin(s), the so-called Fast-Death Factor (FDF) or microcystin caused death in mice within 3 hours. In most samples associated bacterial toxin(s), the so-called Slow-Death Factor (SDF) causing death within 4 to 48 h were possibly involved in SDF intoxication symptoms and mortality. Suspensions of O. agardhii were also lethal. Syptoms and mortality can be attributed to at least two toxic factors. One resembling FDF, the other possibly resulting from associating bacteria. Administration of G. echinulata suspensions did not kill mice but produced symptoms of illness. The symptoms were not consistent with those of Microcystis FDF or SDF. (Murphy-IVI)

MACROBENTHIC FAUNA OF GREAT LAKE, ARTHURS LAKE AND LAKE SORELL, TASMANIA,
Tasmania Univ., Hobart (Australia). Dept. of Zoology.
W. Fulton.
Australian Journal of Marine and Freshwater Research, Vol. 34, No. 5, p 775-785, 1983. 2 Tab, 47 Ref.

Descriptors: *Benthic fauna, *Great Lake, *Arthurs Lake, *Lake Sorell, *Tasmania, Australia, Population dynamics, Population density, Ecosystems, Lake fisheries, Fish establishment.

Tasmanian lakes have similar numbers of species to comparable systems overseas. It is best to know as much as possible about Tasmanian lakes in order to provide a basis for fisheries management. The benthic fauna as well as each lake's characteristics can provide insight into fisheries management. The benthic fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania, contained 88 species, with 48-55 species in each lake. All three lakes had abundant and generally similar chironomid faunas. Arthurs Lake and Great Lake shared common oligochaete species of which only some were numerous in Lake Sorell. The crustacean faunas of each lake differed in composition and abundance, with amphipod species being the most abundant group in Arthurs Lake. Gastropod mollusks were the most abundant group in the fauna of Lake Sorell, and chironomids were most numerous in Great Lake. (Murphy-IVI)
W84-03125

QUALITATIVE AND QUANTITATIVE VARIATION IN THE MACROBENTHIC FAUNA OF THE ORIGINAL LAKE AND NEW LAKE AREAS OF GREAT LAKE AND ARTHURS LAKE, TASMANIA,
Tasmania Univ., Hobart (Australia). Dept. of Zoology.
W. Fulton.
Australian Journal of Marine and Freshwater Research, Vol. 34, No. 5, p 787-803, 1983. 7 Fig, 6 Tab, 27 Ref.

Descriptors: *Qualitative analysis, *Quantitative analysis, *Benthic fauna, *Great Lake, *Arthurs Lake, *Tasmania, Australia, Lake morphology, Biomass, Water level fluctuations, Environmental factors, Ecosystems.

Faunal variation between sample sites in Great Lake and Arthurs Lake, using both qualitative and quantitative data could be useful in eventual fisheries management. Cluster analysis and principal coordinates analysis showed that the fauna of the original lake areas of both lakes is distinct from the fauna of the newly flooded areas. Closer relationships exist between the faunas of the old level of the two lakes than between the faunas of the old and new levels within either lake. The distinction is not attributable to depth but may be influenced by substrate differences. Abnormal fluctuations in water level may affect benthic populations in several ways. These include changes in water chemistry, elimination of macrophytes, alteration of substrates by erosion and exposure of substrates to air or ice cover. The sites at the old level were dominated by oligochaetes whereas chironomids contributed most to the sites at the new level. Consistent seasonal peaks were evident in the biomass at sites at the new level but not at sites at the old. The mean annual biomass levels (wet wt) for Great Lake (13.9 g/sq m) and Arthurs Lake (35.9 g/sq m) are comparatively above average values for other Australian and overseas lakes. (Murphy-IVI)

THE ALGAL COMMUNITIES OF THE UPPER BELGIAN MEUSE AND THE WATER QUALITY: A SYNTHESIS AT FALL 1981 (LES COMMUNAUTES ALGALES DE LA HAUTE MEUSE BELGE ET LA QUALITE DE SES EAUZ: UN BILAN A L'AUTOMENE 1981),
Liege Univ. (Belgium). Dept. of Botany.
J.-P. Descy.
Bulletin de la Society Royale de Botanique de Belgique, Vol. 116, No. 1, p 31-50, 1983.

Descriptors: *Meuse River, *Belgium, *Water quality, *Algae, Diatoms, Chrysophyta, Chlorophyta, Cyanophyta, Biomass, Plankton, Benthos.

In samples taken in the Upper Belgian Meuse in the autumn of 1981, 126 taxa of microscopic algae were identified in the plankton. The chrysophytes (almost all diatoms) and chlorophytes comprized 62.7 and 30.2%, respectively. Quantitative analysis of samples taken from three sites shows the same

trend, with a dominance of diatoms (60.6-64.7% of phytoplankton) and chlorophytes (27.9-34.0%). The remainder are almost all cyanophytes. There was a peak of biomass at the beginning of September, and a marked diminution at the beginning of October. The microphytobenthos included 122 taxa of diatoms (samples were taken between 1976-1981 from three sites). The dominant diatoms are basophilic species of biotypes 4 and 5. The majority of the taxa are pollution-sensitive, demonstrating good water quality. (Moore-IVI)

PRODUCTION AND DISTRIBUTION OF BENTHIC MICROALGAE IN THE LITTORAL SEDIMENTS OF MIKOLAJSKIE LAKE,
Rostock Univ. (German D.R.).
N. Wasmund, and A. Kowalczewski.
Ekologia Polska, Vol. 30, No. 3-4, p 287-301, 1982. 6 Fig, 2 Tab, 16 Ref.

Descriptors: *Littoral environment, *Algae, Benthic environment, Primary productivity, Lakes, Littoral zone, Mikolajskie Lake, Sediments.

Lake littoral is a specific environment characterized, among other things, by a great accumulation of algal biomass. For Mikolajskie Lake both chlorophyll and biomass in the top layers of sediments is related with the degree of site exposition to wave action, suggesting an easy transport of algae by waves to other sites of the littoral, or/and within the sediments. Vertical movements of benthic microalgae were noticed during the day. Photosynthetic activity of these algae was lower than that of other algal communities. Sampling techniques allowed the separation of sediment layers 1 cm thick down to the depth of 10 cm. Production was estimated in place for practically undisturbed samples. There is a distinguished vertical differentiation of the amount of chlorophyll and biomass, especially at a site protected against the wave action. Diurnal vertical migrations of benthic microalgae were visible. The quick diminution of light within sediments limited the production of these algae to the upper few millimeters of sediments. Production of benthic microalgae seems to be better related with the amount of chlorophyll than with biomass determined from cell volumes. Benthic microalgae may be the most important algal producer in shallow littoral communities. (Murphy-IVI)

THERMAL CONDITIONS OF BOTTOM SEDIMENTS IN FIVE SHALLOW LAKES OF MASURIAN LAKELAND,
Panstwowy Inst. Hydrologiczno-Meteorologiczny, Mikolajki (Poland). Regional Observatory.
S. Tyczynska.
Ekologia Polska, Vol. 30, No. 3-4, p 303-325, 1982. 5 Fig, 3 Tab, 19 Ref.

Descriptors: *Thermal stratification, *Bottom sediments, *Shallow lakes, *Masurian Lakeland, Heat budget, Lake sediments, Thermal properties, Temperature gradient, Sediment-water interfaces, Poland.

Thermal conditions of bottom sediments to the depth of 4 m distinguish four thermal periods in a year. They are characterized by normal (June-August), reverse (December-March), spring and autumn (no homothermy). In the summer the epilimnion is the water and the thermocline and hypolimnion is in the sediments for all thermal zones in deep lakes. In the winter temperatures under the ice in the top layers of sediments increases in the shallowest lake (mean depth 0.6 m), whereas in other lakes the temperature decreases. The heat budget of sediments to total heat budget of the lake is reversely proportional to the depth of the lake and according to meteorological conditions is 28-42% in Gardynskie Lake (mean depth 2.4 m) and 56-70% in Lake Luknajno (mean depth 0.6 m). DISTRIBUTION OF FISH AND FOOD OF ROACH RUTILUS RUTILUS, BLEAK ALBURNUS ALBURNUS BREAM ABRUMIS BRAMA AND RUFFE ACERINA CERNUA IN LAKE VANSJO, SOUTH-EAST NORWAY (FORDELING AV FISK, SAMT ERNAERING HOS MORT, LAUE, BRASME OG HORK I VANSJO, OSTFOLD),
Oslo Univ. (Norway). Lab. for Freshwater Ecology and Inland Fisheries.
A. Brabrand.
Fauna, Vol. 36, No. 2, p 57-64, 1983. 3 Fig, 3 Tab, 26 Ref.

Descriptors: *Roach, *Bleak, *Bream, *Ruffe, *Fish food, *Lake Vansjo, *Norway, Fish diet, Fish behavior, Food habits, Aquatic habitats, Distribution patterns, Fish populations.

Fish fauna distribution in different parts of the meso-/eutrophic lake Vansjo, SE Norway were dominated by roach, bleak, bream, white bream, perch and ruffe in the shallow parts of the lake, while roach and bleak were also pelagically at night, in the upper water masses. In the littoral, roach had a variable diet including cladocerans, insect larvae and vegetation, while cladocerans were by far the most dominating food item for bleak. Pelagically both fed on cladocerans. Bleak size selected Bosmina and Daphnia. Bream and ruffe were both bottom feeders. Ruffe selected much more for animal food compared to the bream, which had a high proportion of sediments in their guts. (Murphy-IVI)

THE ECOLOGY OF LAKE NAKURU (KENYA); IV. BIOMASS AND DISTRIBUTION OF CONSUMER ORGANISMS,
Munich Univ. (Germany, F.R.). Zoologisches Inst.
E. Vareschi, and A. Vareschi.
Oecologia, Vol. 60, No. 1, p 70-82, 1984. 13 Fig, 6 Tab, 50 Ref. German Science Foundation grants Ja 145/5 and 145/7.

Descriptors: *Ecology, *Lake Nakuru, *Kenya, *Biomass, Aquatic productivity, Consumer organisms, Saline lakes, Alkaline water, Ecosystems, Ecological distribution.

Consumer biomass and spatial distribution data provide the basis for estimating feeding and production rates, and for quantifying energy flow at the consumer level for the equitorial alkaline-saline Lake Nakuru. An outstanding characteristic of the lake is its biological simplicity. In order to estimate temporal biomass changes of all lake organisms, samples were taken at 19 stations at monthly intervals. The biomass of the only planktonic crustacean, the copepod Lovenuia africana was very high (1.5 g dry weight/cu m) in 1972 and 1973. Lovenula was absent in 1974 and 1975, and at very low levels in part of 1976. For short periods rotifers can be the dominant species of Lake Nakuru. During high salinity periods (greater than 20%) Hexarthra jenkinae occurred in very low numbers. Aquatic heteroptera (four species) contributed 0.4% to total consumer biomass in 1972 and 1973. In 1974-1976 the lake had no aquatic heteroptera. Benthic biomass (0.4 g dry weight/sq m) consisted almost exclusively of Leptochironomus deribae. For birds, Pelecanus onocrotalus accounts for approximately 90% of the biomass with peak densities of almost 20,000 birds. (Murphy-IVI)

THE ECOLOGY OF LAKE NAKURU (KENYA); V. PRODUCTION AND CONSUMPTION OF CONSUMER ORGANISMS,
Munich Univ. (Germany, F.R.). Zoologisches Inst.
E. Vareschi, and J. Jacobs.
Oecologia, Vol. 61, No. 1, p 83-98, 1984. 7 Fig, 13 Tab, 77 Ref. German Science Foundation grants Ja 145/5 and Ja 145/7.

Descriptors: *Lake Nakuru, *Kenya, *Production, *Consumption, *Consumer organisms, Energy balance, Rotifers, Copepods, Chironomids, Fish, Birds, Biomass, Water fowl.

Production and consumption rates were estimated from the distribution of numbers and size classes in the lake and laboratory experiments on growth and filtration rates. Data from consumer production and consumption in Lake Nakuru from 1972 to 1976, provide the basis for estimating the major pathways of energy flow. Rotifers (Brachionus dimidiatus and B. plicatilis), not especially significant in biomass, had the highest production rates. Consumption rates were correspondingly high. Copepods almost matched rotifers in 1972/73 but vanished from the lake in the following years. Chironomid larvae and fish had similar ranges of production and consumption. The fish had about twice the biomass of the insects. Most primary consumer organisms fed on the dominant primary producer, the cyanophyte Spirulina platensis, but rotifers and Leptochironomus met an unknown fraction of their energy requirements by consuming bacteria and detritus. The total fish yield taken by birds was 2,700-9,500 metric tons (wet weight) per year. (Murphy-IVI)

A QUANTITATIVE STUDY OF PHYTOPLANKTON OF THE RIVER GANGES AT BHAGALPUR, INDIA,
Bhagalpur Univ. (India). Post-Graduate Dept. of Botany and Zoology.
N. K. Singh, J. S. D. Munshi, and K. S. Bilgrami.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 2, p 81-87, 1983. 1 Fig, 2 Tab, 32 Ref.

Descriptors: *Phytoplankton, *Ganges River, *Bhagalpur, *India, Phosphorus, Nitrogen, Silicates, Chlorides, Temperature effects, Thermal stress, Benthos, Biomass.

Samples of Ganges River surface water were collected at monthly intervals from January, 1978 to December, 1978 using a water sampler. The maximum phytoplankton standing stock was in the summer with the highest peak in May when the water temperature was between 26 to 35 C. There was a sharp fall in standing stock when turbidity was very high. Free carbon dioxide was absent during active growth of phytoplankton (January to May) due to its utilization in photosynthesis. The pH rose during this period. The silicate level was considerably reduced when the standing stock of diatoms was maximum. Phosphorus and total nitrogen of water expressed inverse correlation to phytoplankton standing crop. Phosphorus, silicate and total nitrogen levels were higher during the rains while the chloride concentration rose during the summer. (Murphy-IVI)

MIXING PROCESSES IN LAKES: MECHANISMS AND ECOLOGICAL RELEVANCE,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
D. M. Imboden, U. Lemmin, T. Joller, and M. Schurter.
Schweierische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 11-44, October, 1983. 21 Fig, 4 Tab, 38 Ref.

Descriptors: *Mixing, *Hypolimnion, *Lake Baldegg, *Switzerland, Tracers, Radon, Tritium, Helium radioisotopes, Water circulation, Kinetic energy, Wind, Heat exchange, Stratification, Internal waves, Energy transfer, Density gradients.

In Lake Baldegg, Switzerland (surface area 5.3 sq km, maximum depth 66 m) the analysis of data from moored instrument systems (atmospheric boundary layer, lake temperature distribution, bottom currents) was correlated to the long-term development of vertical mixing as seen from profiles of natural isotopes (radon-222, tritium and helium-3) and chemical species. Since the input of

kinetic energy by inlets is small, mixing in the lake is mainly driven by wind and heat exchange at the surface. During most of the year, thermally and chemically induced density stratification prevents the energy input from penetrating into greater depths. Part of the energy is trapped in internal waves running along the thermocline with little damping. Mixing in the surface layer is highly transient in nature. Strong temperature gradients develop in the surface layer on warm, calm days. Internal waves dominate the internal dynamics during stratification. Internal waves seem to be an important mechanism for kinetic energy transfer to the hypolimnion. The coherence between internal seiching and periodicities in the bottom currents supports this point. The indirect nature of energy transfer makes hypolimnion mixing less sensitive to meteorological forcing as long as stratification is well-developed and winds are not too strong. When vertical density gradients become weak, direct coupling between wind forces and mixing at all depths is observed. Internal loading is very significant in Lake Baldegg. Water ages, traced by helium and tritium, question the idea that as far as vertical mixing goes, stagnation and circulation are two well-distinguishable states of the lake. Renewal of deep hypolimnic water is significant even during stratification. (Moore-IVI)

CHEMICAL AND GEOCHEMICAL STUDIES OF LAKE BIEL; II. A CHEMICAL APPROACH TO LAKE MIXING,
Bern Univ. (Switzerland). Dept. of Inorganic Chemistry.
U. P. Uyffeler, P. W. Schindler, U. E. Wirz, and D. M. Imboden.
Schweizerische Zeitschrift fur Hydriologie, Vol. 45, No. 1, p 45-61, October, 1983. 12 Fig, 2 Tab, 24 Ref.

Descriptors: *Lake Biel, *Switzerland, *Mixing, *Eddy diffusion, Water temperature, Radon, Tracers, Water circulation, Chemical properties.

The mixing parameters in Lake Biel (Switzerland) are established in terms of coefficients of eddy diffusion in a two-dimensional box model. The vertical eddy diffusion coefficients were determined as a function of depth and time using the temperature method. Simultaneously with the temperature, the vertical excess Rn-222 concentration (*Rn-222) was measured. For observed transient Rn-222 distribution, transport by advection was included in the model calculations. A reasonable modelling of photosynthesis requires vertical subdivision of the epilimnion. Simultaneous measurements along one profile of two tracers that differ in the directions of their propagation give access to both vertical and horizontal lake mixing. The special suitability of Rn-222 is based on its short half-life time that produced high concentration gradients and permited recording short time phenomena. This method is restricted to comparatively small basins and to lake systems with Ra-226 bearing sediments. The eddy diffusion coefficients give an appropriate description of the observed distribution of both temperature and *Rn-222, but have limited physical significance as they are operationally defined in terms of an arbitary model. HYDRODYNAMICS OF THE LAKE OF GENEVA,
Ecole Polytechnique Federale de Lausanne (Switzerland). Lab. d'Hydraulique.
W. H. Graf.
Schweizerische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 62-100, October, 1983. 28 Fig, 3 Tab, 21 Ref.

Descriptors: *Hydrodynamics, *Lake Geneva, *Lake Leman, *Switzerland, Orography, Hydrologic models, Model studies, Wind waves, Water circulation, Mathematical models, Air-water interfaces, Wind-driven currents, Mixing, Seiches, Storm surges.

In a certain sense, Lake Leman is an artifical lake since it is regulated hydraulically at Geneva (Switzerland). Extensive meteorological information, coupled with atmospheric dynamics over the lake helped develop working mathematical models. Air stability plays an important role for weak winds. Medium and strong winds are near neutral. Wind driven movement and wind generated surface waves are the types of lake motion which contributes to the movement (and mixing) in lake Leman and as to what types of wave climates exist. The movement in lakes is mathematically represented with a set of equations, namely the equations of continuity, of momentum, of heat conduction, of diffusion of matter and of state. For an incompressible, homogeneous and shallow lake, where the horizontal mixing is negligible compared with vertical mixing, the linearized system of equations are integrated. The steady-state circulation model and the storm surge and seiche models also use integrated mathematical models. (Murphy-IVI)

K. Hutter.
Schweizerische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 101-144, October, 1983. 26 Fig, 3 Tab, 81 Ref.

Descriptors: *Hydrodynamics, *Lake Zurich, *Lake Lugano, *Switzerland, *Mathematical models, *Water currents, Wind-driven currents, Hypolimnion, Isotherms, Seiches, Model studies, Density, Water temperature.

Density distribution and temperature and current data measured in Lake Zurich and Lake Lugano during two summer field programs are interpreted by means of hydrodynamic models. With the exception of the hypolimnion current the employed set of instruments was suitable to reliably measure the 'lake relevant' physical quantities. Comparisons of the time series of the isotherm depths permits correlation of the observed wind induced oscillations with the internal seiches behavior. Time series of limnigraphs mounted along the shores permit identification of the periodic barotropic components of the motion. By applying the shallow water equations to Lake Zurich, the periods and the structures of (even high) surface seiches are reliably predicted. For satisfactory prediction of wind-induced barotropic motions of Lake Zurich a three-dimensional circulation model is used. The nonlinear advective terms must be included in this analysis. Internal seiches are treated with a linear two-layer model, and periods and structures of the eigenmodes are well predicted with it. Baroclinic wind-induced motions are modelled by a three-dimensional FD-Model which is tested using a real, measured wind field. The motion, which is directly influenced by the wind is reliably predicted. The oscillations in the numerical model after the wind cessation are too attenuated. (Murphy-IVI)

NUMERICAL MODELS FOR THE CURRENTS SIMULATION OF A LAKE (MATHEMATISCHE MODELLE ZUR SIMULATION VON ZIRKULATIONSSTROMUNGEN IN EINEM SEE),
Laboratorio di Fisica Terrestre, Lugano-Trevano (Switzerland).
D. Bozzolo, R. Pamini, G. Salvade, F. Solca, and C. Spinedi.
Schweizerische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 145-175, 1983. 30 Fig, 13 Ref.

Descriptors: *Mathematical models, *Computer models, *Lakes, *Water currents, Simulation, Wind-driven currents, Thermodynamics, Mixing, Thermal pollution, Water circulation, Lake Lugano.

The three-dimensional, finite-difference model o the physical processes in a lake has been adapted t the simulation of wind-induced currents and ther mal processes in the northern basin of Lak Lugano. The advantages of the model are the us of complete hydrodynamic and thermodynami equations, with only the Boussinesq approximatio and the modelling of eddy viscosity through dynamic algorithm. The model can simulate wind induced currents in a stratified lake, including a thermal interactions and inflows. Because of th size of the computer program, the model take long computation times in a large core compute The model includes all thermal interactions wit the atmosphere, wind-induced mixing processes inflows and outflows. The model predictions ar compared with data collected in 1979. A furthe application of the model is the cold inflow simula tion in a stratified basin with inclusion of turbuler vertical exchange processes. A two-dimensiona version of the model, which assumes an hydrosta ic presssure distribution, is utilized to simulate th thermal summer development of Lake Lugano during 40 days. The model includes the therma interactions and wind influence. The three-dimen sional model can be applied to current simulatio in lake basins. The two-dimensional model may b utilized to predict the development of a basi subject to a thermal load. (Moore-IVI)

Schweizerische Zeitschrift fur Hydrologie, Vo 45, No. 1, p 333-343, October, 1983. 3 Fig, 21 Re

Descriptors: *Submerged plants, *Running water *Carbon, Hardness, Plant metabolism, Roots, Fol age, Uptake, Translocation.

Uptake, translocation and release of inorgani carbon were tested in partitioned chambers wit submersed running water macrophytes from har water habitats (Potamogeton coloratus, Ranunc lus fluitans, R. circinatus, Myriophyllum spicatu Callitriche obtusangula and Berula erecta) and fluitans from a soft-water habitat. All species we able to remove labelled inorganic carbon from th water by both systems, foliage and rhizome/ro system, the uptake via foliage predominating clea ly. Most of the carbon taken up by the rhizome root system was translocated into the phytosynth tically active tissues, most likely as an inorgani species of carbon dioxide. The reversed transloc tion was rather small with most of the specie probably due to short exposure times. Release labelled carbon was below 1% of total uptak except for C. obtusangula and R. fluitans from th soft-water habitat. The low carbon release is reasonable adaptation to the constantly renewi milieu in running-water habitats. (Moore-IVI)

OXYGEN REGIME IN A FISHPOND WIT DUCKWEEDS (LEMNACEAE) AND CERAT PHYLLUM,
Ceskoslovenska Akademie Ved, Trebon. Dept. Hydrobotany.
J. Pokorny, and E. Rejmankova.
Aquatic Botany, Vol. 17, No. 2, p 125-137, Oct ber, 1983. 3 Fig, 4 Tab, 21 Ref.

Descriptors: *Duckweed, *Ponds, *Oxygen ba ance, Fish, Phytoplankton, Vegetation, Lemn ceae, Ceratophyllum, Nutrients,.

In small fishponds, usually highly eutrophic, co munities of Ceratophylletum demersi with a cov of duckweeds occurs. Through their relative high biomass this vegetation influences the g regime in the fishponds. The depth of oxygen a the daily changes in oxygen concentration we

assessed by in situ measurements in stands of Lemnaceae, Ceratophyllum, Lemnaceae plus Ceratophyllum, and phytoplankton at the peak of the vegetation season. With the aim of excluding the influence of phytoplankton on the diurnal oxygen course, oxygen concentrations were measured in near natural conditions below both the dense and the loose covers of Lemnaceae, placed in nutrient solution. The duckweeds Lemna minor and Spirodela polyrhiza did not release any oxygen into the water on which they were floating. The frequently occurring combination of submerged Ceratophyllum with floating ducksweeds improves the oxygen concentration in the fishpond water as compared with water covered only by duckweeds. Oxygen is transported from the upper aerated water layers to the bottom of the shallow pond. The average oxygen concentration was up to 2 mg/liter lower when sediments were present, and the flow of oxygen to the bottom amounted to 4 g/sq m/day. (Baker-IVI)

IMPACT OF ACIDIFICATION AND EUTROPHICATION ON MACROPHYTE COMMUNITIES IN SOFT WATERS IN THE NETHERLANDS. I. FIELD OBSERVATIONS,
Katholieke Univ., Nijmegen (Netherlands). Lab. of Aquatic Ecology.
J. G. M. Roelofs.
Aquatic Botany, Vol. 17, No. 2, p 139-155, October, 1983. 1 Fig, 6 Tab, 41 Ref.

Descriptors: *Eutrophication, *Acidification, Macrophytes, Netherlands, Littoral environment, Aquatic life, Light intensity.

Aquatic habitats appear to be very susceptible to the effects of acidification. The mechanisms of acidification, however, appear to be very complex and are not yet clearly understood. A strong decline has been noticed in the number of waters dominated by Littorellion species during the last decades. These have been mainly isoetids such as Lobelia dortmanna L., Isoetes lacustris L., and Littorella uniflora (L.) Aschers. Investigations were carried out at 68 locations where the waters were known to be dominated by L. uniflora after 1950. In 1980, L. uniflora appeared to be absent or to have strongly decreased in 53 (78%) of these waters. In 41 of them, Littorella had been replaced by submerged Juncus bulbosus L. and/or Sphagnum spp. Changed inorganic carbon budgets appear to be responsible for the changes resulting as an effect of acidification. Eutrophication of the water and/or sediment in the remaining 12 water sources seems to be responsible for the changes in the plant communities. Enrichment with phosphate of the mineral sediment alone led to luxurious growth of submerged, rooted macrophyte species such as Myriophyllum alterniflorus DC and Ranunculus peltatus Schrank. Phosphate-enrichment of both sediment and water led to luxurious growth of pleustophytes such as Riccia fluitans L. and Lemna minor L. in small, shallow waters and to plankton bloom and growth of epiphytes in larger, deeper waters. Light limitations seem responsible for the disappearance or decline of the Littorellion species. (Baker-IVI)

CARBONATE MINERALOGY OF LAKE SEDIMENTS AND SURROUNDING SOILS. 2. THE QU'APELLE LAKES,
Saskatchewan Univ., Saskatoon. Dept. of Soil Science.
K. Ghebre-Egziabhier, and R. J. St. Arnaud.
Canadian Journal of Soil Science, Vol. 63, No. 2, p 259-269, May, 1983. 5 Fig, 3 Tab, 13 Ref. NSERC Grant No. A1446.

Descriptors: *Lake sediments, *Carbonates, Mineralogy, Lakes, Sediments, Qu'Appelle Lake, Magnesium, Dolomite, Erosion.

The nature and distribution of carbonate minerals in the upper Qu'Appelle basin in south-central Saskatchewan were investigated. Erosional effects appear to have resulted in sediments which were derived largely from neighboring landscapes. Of particular importance is the build-up of carbonates in these sediments in situations where the water chemistry of the lake waters favors precipitation of calcium carbonate. Waters in the Fishing Lakes (Pasqua, Echo, Katepwa) contain appreciably more soluble salts than Buffalo Pound Lake upstream from them. The increased $CaCO_3$ contents of the sediments in going from the Buffalo Pound to the Pasqua, and Echo Lakes coincide with the increased ionic concentrations of calcium and carbonate ions, as reflected by increasing ionic activity products. This parallelism plus the presence of Mg-bearing calcites supports the evidence indicating that carbonates are being precipitated in the lakes. (Baker-IVI)

THE IMPACT OF ZOOPLANKTON FEEDING ON THE EPILIMNETIC BACTERIA OF A EUTROPHIC LAKE,
Wisconsin Univ.-Madison. Dept. of Bacteriology.
C. Pedros-Alio, and T. D. Brock.
Freshwater Biology, Vol. 13, No. 3, p 227-239, June, 1983. 4 Fig, 4 Tab, 43 Ref. NSF grant DEB-8212459.

Descriptors: *Zooplakton, *Feeding rates, *Epilimnion, *Bacteria, *Eutrophic lakes, Ecological effects, Biomass, Lake Mendota, Population dynamics.

In order to elucidate the importance of zooplankton feeding on bacteria in Lake Mendota, biomass and production of heterotrophic bacteria have been measured over a 2 year period and while the biomass was fairly constant from year to year, production was very high from June to October. Feeding of zooplankton on bacteria was measured by a cell counts method in 1979 and using radioactively labelled natural assembleges of bacteria in 1980. Total feeding was calculated and was found to account for 1-60% of the bacterial heterotrophic production. Annually, it accounted for 1-10% of the bacterial heterotrophic production. Since bacterial biomass does not change significantly from year to year and yet bacterial production is very high compared to feeding by zooplankton, mechanisms other than feeding must exist which remove biomass from the epilimnetic bacteria in larger amounts. THE EFFECTS OF SURFACE GEOLOGY AND STREAM SIZE ON FRESHWATER MUSSEL (BIVALVIA, UNIONIDAE) DISTRIBUTION IN SOUTHEASTERN MICHIGAN, U.S.A.,
Cornell Univ., Ithaca, NY. Section of Ecology and Systematics.
D. Strayer.
Freshwater Biology, Vol. 13, No. 3, p 253-264, June, 1983. 8 Fig, 2 Tab, 42 Ref.

Descriptors: *Mussels, *Habitats, Michigan, Mollusks, Turbidity, Streams, Catchment areas, Aquatic habitats.

Stream size and surface geology are the two major environmental features controlling the distribution of the 34 species of unionid mussels living in streams in southeastern Michigan. Surface geology, a previously unrecognized factor in the ecology of freshwater mussels, regulates the hydrology, slope and turbidity of streams in this area. Reciprocal averaging ordinations are used to aid the description of the habitats occupied by each mussel species. Thus the theory that the catchment of a stream is partially responsible for the biota of that stream has been verified. In general, conditions at any site along a stream are defined both by constraints that are imposed on all running waters such as hydraulic geometry and by the catchment of that particular stream. THE PHYSICAL LIMNOLOGY OF AUGHER LOUGH (NORTHERN IRELAND),
New Univ. of Ulster, Coleraine (Northern Ireland). Limnology Lab.
B. Ripley.
Freshwater Biology, Vol. 13, No. 4, p 353-362, August, 1983. 7 Fig, 3 Tab, 33 Ref.

Descriptors: *Limnology, *Augher Lough, *Ireland, Thermal stratification, Hypolimnion, Oxygen deficit, Thermocline, Epilimnion, Hypolimnion, Eddy diffusion, Heat budget.

The physical limnology of Augher Lough, Northern Ireland (area = 9.25 ha, mean depth = 5.5 m), including stratification pattern, heat budget, thermocline erosion rate, eddy diffusion rate in the thermocline and hypolimnion and areal hypolimnetic oxygen deficit provides a suitable background for an examination of the recent sedimentary record. The aim is to present a description of the physical limnology of Augher Lough and to compare this with the behavior expected from the relationships of physical limnology. Oxygen and temperature profiles, at two sites during 1978 and four sites during 1979, showed that spatial variability of these quantities was low and allowed the following lake characteristics to be estimated. Heat budget was 5.30 kcal/sq cm (standard deviation = s = 0.26) in 1978 and 5.00 (s = 0.26) in 1979. The thermocline depth was 3.5-6.5 m with an erosion rate of 1.9 x .000001 m/s in 1979. Eddy diffusion coefficients of heat in the thermocline and hypolimnion normally ranged from 0.48 x 0.1 sq cm/s (s = 0.20 x 0.1) to 5.4 x 0.1 (s = 2.6 x 0.1), but reached 10 x 0.1 sq cm/s (s = 9 x 0.1) in early July 1978 after a cooling-mixing episode in the epilimnion. The hypolimnetic oxygen deficit was 680 mg O_2/sq m/d (s = 76) and varied strongly with depth. A cooling-mixing episode in the epilimnion in June-July 1978 caused the movement of heat down to 8 m, movement of oxygen down to 6 m and increased the eddy diffusion coefficients of heat by an order of magnitude. BIOMASS AND PRODUCTION OF PHYTO- AND BACTERIO-PLANKTON IN EUTROPHIC LAKE TYSTRUP, DENMARK,
Copenhagen Univ., Hilleroed (Denmark). Det Ferskvands-Biologiske Lab.
B. Riemann.
Freshwater Biology, Vol. 13, No. 4, p 389-398, August, 1983. 4 Fig, 3 Tab, 37 Ref.

Descriptors: *Biomass, *Phytoplankton, *Bacterioplankton, *Eutrophic lakes, *Lake Tystrup, *Denmark, Primary productivity, Organic matter, Bacteria.

The phytoplankton in eutrophic lakes plays a dominant role in the production of organic matter. Decomposition and mineralization of the organic matter are mainly bacterial processes. Phytoplankton primary production and biomass were compared with bacterial secondary production estimated by means of frequency of dividing cells (FDC) in eutrophic Lake Tystrup, Denmark. In the upper part of the photic zone, bacterial secondary production constituted 12% of the carbon fixed by the phytoplankton. In vertical profiles, bacterial secondary production ranged from 7.6% (early spring) to 121% (during August) of the carbon fixed by the algae. A close relationship was found between occurrence and activity of bacteria, and algae, suggesting that released organic products are of primary importance to the bacteria. The annual phytoplankton primary production was estimated as 227 g C/sq m compared to 102 g C/sq m assimilated by the bacteria, so 45% of the carbon

fixed by the photoplankton went through pelagic bacteria. (Murphy-IVI)

THE COLONIZATION OF BALL-CLAY PONDS BY MACROINVERTEBRATES AND MACROPHYTES,
Exeter Univ. (England). Inst. of Biometry and Community Medicine.
L. E. Barnes.
Freshwater Biology, Vol. 13, No. 6, p 561-578, December, 1983. 8 Fig, 3 Tab, 37 Ref.

Descriptors: *Community development, *Ponds, *Macroinvertebrates, *Macrophytes, Population dynamics, Population density, Hydrogen ion concentration, Principal component analysis.

To provide information of practical application in the management of new ball-clay ponds in the present study, it was necessary to investigate colonization over a much longer time-span and to include both macrophytes and macroinvertebrates. The rate and nature of colonization of ball-clay ponds by aquatic macrophytes and macroinvertebrates were studied by comparing communities present in a series of ten ponds of similar dimensions, but of different ages, ranging from 6 months to 15 years. Multivariate analyses of the biotic data distinguished between 'neutral' and 'acid' ponds; further analyses concentrated on the former type. Initial colonization of neutral ponds was rapid with a predictable sequence of species arrival, probably reflecting short dispersal distances. Variations in macroinvertebrate invasion times were related to dispersal strategy and ability. As the pond aged, successional changes, linked with macrophyte colonization, produced a shift in dominance from algivores and predators towards epiphyton grazers and detritivores. Some evidence of succession of species within invertebrate orders was found. Low pH affected colonization principally by preventing the establishment of acid-intolerant immigrant species, but also by retarding succession. It is concluded that non-interactive models of insular colonization, with constant immigration and extinction rates, are of limited applicability to pond colonization in temperate areas. (Murphy-IVI)

DIATOMS IN FOUNTAINS, RESERVOIRS AND SOME OTHER HUMID AND DRY LOCALITIES IN ROME, ITALY,
N. Foged.
Nova Hedwigia, Vol. 38, p 433-455, 1983. 1 Tab, 35 Ref.

Descriptors: *Diatoms, *Fountains, *Reservoirs, *Rome, *Italy, Hydrogen ion concentration.

Fountains, reservoirs, waste-pipes and other more or less moist localities in towns are often biotopes with a character of their own and generally fairly rich. The analyzed content from 21 samples collected in 1951 from 17 localities in Rome, Italy (fountains, reservoirs and other humid and dry localities), revealed 135 taxa of diatoms from 31 genera. The water, which in 1951 chiefly came from the surrounding country through aqueducts, was more or less alkaline. (Murphy-IVI)

LIFE HISTORY AND ECOLOGY OF THE HUMPBACK CHUB IN THE LITTLE COLORADO AND COLORADO RIVERS OF THE GRAND CANYON,
Fish and Wildlife Service, Flagstaff, AR. Colorado River Fishery Project.
L. R. Kaeding, and M. A. Zimmerman.
Transactions of the American Fisheries Society, Vol. 112, No. 5, p 577-594, September, 1983. 11 Fig, 5 Tab, 21 Ref.

Descriptors: *Fish, *Rivers, Colorado River, Little Colorado River, Grand Canyon, Seasonal variations, Littoral environment, Darkness, Light intensity, Habitats, Aquatic habitats, Fish behavior, Humpback chub.

The loss of habitat for some native fishes of the Colorado River drainage coincided with the closure of Flaming Gorge Dam on the Green River. Humpback chubs in the Little Colorado River grew rapidly to about 250-300 mm in length at 3 yr of age, the onset of reproductive maturity for the female. Annual reproductive success was greatest when spawning coincided with seasonal river runoff. Use of the physical habitat by age-0 and juvenile humpback chubs was affected by light intensity. Shallow littoral areas were used during darkness, but during daylight only when the water was turbid. Year-round low temperatures in the Colorado River did not inhibit seasonal gonadal maturation of humpback chubs. However, lab studies indicate that such low temperatures result in nearly complete mortality of embryonic and larval humpback chubs. Persistence of the fish in the Little Colorado River could be attributable, in part, to the unsuitablility of that environment, and that of the Colorado River, for potential competitor or predator species in the drainage. (Baker-IVI)

MORTALITY OF WALLEYE EGGS AND RAINBOW TROUT YOLK-SAC LARVAE IN LOW-PH WATERS OF THE LACLOCHE MOUNTAIN AREA, ONTARIO,
Trent Univ., Peterborough (Ontario). Dept. of Biology.
P. F. Hulsman, P. M. Powles, and J. M. Gunn.
Transactions of the American Fisheries Society, Vol. 112, No. 5, p 680-688, September, 1983. 5 Fig, 2 Tab, 26 Ref.

Descriptors: *Mortality, *Walleye, *Trout, *Larvae, *Acid waters, *LaCloche mountains, *Ontario, Streams, George Lake, Hydrogen ion concentration, Acidity, Acidic water, Toxicity.

Freshly fertilized eggs of walleye Stizostedion vitreum were incubated in the outlet waters of George Lake (pH 5.4) and sections of a nearby stream (pH 6.0, 6.6). Walleye egg mortality was low (25.5-33.5%) at pH 6.0. High mortality (90.5%) occurred between fertilization and the eyed-egg stage at the pH 5.4 site. Mortality of rainbow trout yolk-sac larvae approached 100% within 5 days at both pH 4.6 and 5.4. In contrast, total mortality was less than 3% at pH 6.0 and also in low-pH humic water (pH 5.5). The high mortality rate in the acidic outlet waters of George Lake suggests that the acidification of this lake was responsible for the extinction of its walleye stock. The striking differences in mortality of rainbow trout yolk-sac larvae between sites of similar pH (5.4-5.5) indicated that H(+) toxicity was not solely responsible for fish mortality in acid water. (Murphy-IVI)

REDD-SITE SELECTION BY BROOK TROUT AND BROWN TROUT IN SOUTHWESTERN ONTARIO STREAMS,
Guelph Univ. (Ontario). Dept. of Zoology.
L. D. Witzel, and H. R. MacCrimmon.
Transactions of the American Fisheries Society, Vol. 112, No. 6, p 760-771, November, 1983. 3 Fig, 6 Tab, 43 Ref. National Sciences and Engineering Research Council of Canada grant A1719.

Descriptors: *Fish behavior, *Streams, *Habitats, Canada, Ontario, Trout, Fish, Aquatic habitats. Redd-substrate composition, water velocity, depth, and other environmental variables associated with redd-site selection and spawning by brook trout and brown trout were examined in southwestern Ontario streams. Sympatric and allopatric populations spawned in similar ranges of specific conductance (225-810 micromhos/cm), pH (7.0-8.2), dissolved oxygen (greater than 83% saturation), and stream gradient (0.2-2.3%). Brook trout spawned only in areas of groundwater seepage, typically near headwaters where streamflow did not exceed 177 liters/second. Brown trout spawned in a wider range of flows and used locations both with and without groundwater seepage. Reuse of redds was mostly intraspecific. Mean water depth over redds selected by brook and brown trout were similar. However, mean stream velocities were significantly slower at brook trout (17.6 cm/second) than at brown trout reeds (46.7 cm/second). Redd-site preference by brook trout for the areas of groundwater seepage and by brown trout for faster water velocities and coarser substrates minimized species interactions during spawning. REPRODUCTION BY THE ENDANGERED CUI-UI IN THE LOWER TRUCKEE RIVER
Fish and Wildlife Service, Reno, NV.
G. G. Scoppettone, G. A. Wedemeyer, M. Coleman, and H. Bruge.
Transactions of the American Fisheries Society, Vol. 112, No. 6, p 788-793, November, 1983. 5 Fig, 11 Ref.

Descriptors: *Fish behavior, *Rivers, Cui-ui, Lower Truckee River, Reproduction, Fish, Aquatic habitats, Habitats, Reproducibility.

The cui-ui is an endangered species endemic to Pyramid Lake, Nevada, and is thought to be the sole surviving genetically pure member of its genus. Water-project developments dating back to the turn of the century have regulated Truckee River flows and diverted water for agricultural and municipal uses. As a result, the level of Pyramid Lake dropped approximately 25 m, and a large shallow delta formed at the mouth of the river. Adult spawning behavior and emigration of larvae of the endangered cui-ui Chasmistes cujus were studied in a natural side channel of the lower Truckee River. The river phase of cui-ui life appeared to be extremely brief. Most migratory and spawning activity occurred at night. The external radio-tags apparently did not affect spawning behavior. Adults spawned over predominantly gravel substrate under a broad range of water depths and velocities. Eggs were buried to about 10 cm in the substrate. Cui-ui larvae apparently emigrated downstream to Pyramid Lake immediately after swim-up. (Baker-IVI)

COMPARATIVE WATER CHEMISTRY OF FOUR LAKES IN ROCKY MOUNTAIN NATIONAL PARK,
National Park Service, Fort Collins, CO. Water Resources Field Support Lab.
J. Baron.
Water Resources Bulletin, Vol. 19, No. 6, p 895-901, December, 1983. 2 Fig, 2 Tab, 11 Ref.

Descriptors: *Water chemistry, *Mountain lakes, *Rocky Mountain National Park, Colorado, Chemical properties, Inorganic compounds, Biological filters, Weathering, Nitrates, Sulfates.

Lake chemistry is the product of its inputs, components of which include weathering of primary parent materials and soils, biological leachates, and precipitation. The inorganic chemistry of four hi

titude lakes which appear similar superficially as compared to determine what controls variation between them. Weathering from the different pes of parent material caused differing cation oncentrations between the lakes by dissimilar concentrations of those cations which are products of imary weathering. There was s significant difference in anion concentrations between members of ie pair having the same bedrock geology. This fference is attributed to the presence of a wet dge meadow above one of the lakes which serves a biological filter for anions, particularly nitrate d sulfate. Small scale drainage characteristics hich can alter regional atmospheric contributions e important contributors to lake chemistry. Murphy-IVI)

escriptors: *Lakes, *Water quality, *Model studs, Dispersion, Diffusion, Mathematical models, ydrodynamics, Finite difference models, Multie-box models.

n important aspect of lake water quality modelg is the transport due to diffusion and dispersion ocesses. The determination of dispersive transrt is examined relative to model spatial structure d numerical formulation. Two basic model types e identified: the finite difference model (a continm approach); and the multiple-box model (a screte approach). Analysis of these two apoaches indicates that the multiple-box model forulation introduces substantial implicit dispersion a consequence of its discrete structure. Due to is implicit dispersion, multiple-box model exange flow or dispersion parameters cannot be etermined directly based on the hydrodynamics the prototype lake - only calibration is a viable proach. Despite the conceptual advantages of nite difference models over box models, box odels will continue to be used as a simple and st-effective alternative for lake water quality odeling. Box models can serve as a reasonable proximation provided the implicit model disperon is properly considered in model formulation. uidelines are recommended for construction of ultiple-box lake water quality models. STRATIFICATION AND MIXING IN LAKES OF TAYLOR COUNTY, WISCONSIN, WITH EMPHASIS ON RICHTER LAKE,
State Univ. of New York at Buffalo. Dept. of Biological Sciences.
K. M. Stewart, and W. A. Stewart.
Archiv fur Hydrobiologie, Vol. 98, No. 2, p 250-264, October, 1983. 6 Fig, 3 Tab, 29 Ref.

Descriptors: *Stratification, *Mixing, *Winterkill, *Richter Lake, *Wisconsin, Glacial kettle lakes, Dissolved oxygen, Ice cover.

A limnological investigation was carried out on eight lakes (Diamond, Eska, Kathryn, Nineteen, North Twin, Richter, Spruce, and Thirty-three) in the lower Chequamegan National Forest in Taylor County, Wisconsin. The glacial kettle lakes range in area from 2.6 to 25 ha and in depth from 9.1 to 19.2 m. Winterkill occurs in some of these lakes as an occasional or aperiodic event, whereas in others the phenomenon occurs annually with varying degrees of severity. Because most of the lakes are relatively deep with respect to surface area, an explanation for the poor to marginal oxygen conditions was sought. Richter Lake was selected for the most detailed studies. If its vernal and autumnal mixing are fairly representative, then problems of aperiodic winterkill in these small but relatively deep lakes are more easily understood. Richter has long periods of ice and snow cover, a strong winter and summer stratification, an incomplete vernal mixing, and only a brief period of complete autumnal mixing. The lake does not have time to achieve full oxygen saturation in either spring or autumn before the lake restratifies, thus perpetuating marginal conditions which are probably inadequate to handle the organic loading from this mostly forested region. The Secchi visibilities are generally low in these moderately stained waters. Lake Thirty-three has some meromictic characteristics. (Moore-IVI)

PRELIMINARY MEASUREMENTS OF PRIMARY PRODUCTION AND COMMUNITY RESPIRATION IN A FOREST STREAM IN HONG KONG,
Hong Kong Univ. Dept. of Zoology.
D. Dudgeon.
Archiv fur Hydrobiologie, Vol. 98, No. 3, p 287-298, November, 1983. 5 Fig, 29 Ref.

Descriptors: *Primary productivity, *Respiration, *Forest streams, *New Territories, *Hong Kong, Lotic environment, Energy, Dissolved oxygen, Pools, Riffles.

Comparative measurements of primary production (P) and community respiration (R) were undertaken in a shaded riffle reach and an unshaded pool in Tai Po Kau Forest Stream, New Territories, Hong Kong. It was hoped that such a study would enable an assessment of the relative importance of allochthonous and autochthonous carbon sources to the energy budget of the stream as a whole to be made. The procedure employed was the twin curve method involving measurements of dissolved oxygen concentrations at regular intervals over a 24-hour period. Such procedures have rarely been employed in studies of lotic habitats in Asia. Calculated P/R ratios varied between 1.02 in the shaded pool site and 0.17 in the shaded riffle reach. P values recorded in the pool site were considerably higher than those recorded in unpolluted streams in temperate regions. Despite this, it was apparent that the bulk of the energy requirements of the consumers in Tai Po Kau Forest Stream were met from allochthonous sources, such a characteristic probably typifying the metabolism of lotic habitats in forest watersheds. RELATIONSHIPS AMONG CHEMICAL, PHYSICAL, AND BIOLOGICAL INDICES ALONG RIVER CONTINUA BASED ON MULTIVARIATE ANALYSES,
Battelle Pacific Northwest Labs., Richland, WA. Environmental Sciences Dept.
C. E. Cushing, C. D. McIntire, K. W. Cummings, G. W. Minshall, and R. C. Petersen.
Archiv fur Hydrobiologie, Vol. 98, No. 3, p 317-326, November, 1983. 2 Fig, 3 Tab, 26 Ref. NSF grants BMS-75-07333 and DEB-7811671.

Descriptors: *Multivariate analysis, *River Continuum Concept, *Stream classification, Physical properties, Biological properties, Chemical properties, Respiration, Ecosystems, Precipitation, Stream gradient, Stream length, Watersheds.

A variety of multivariate analyses were applied to chemical, physical, and biological data from 16 stream sites to explore the usefulness of these factors in possible stream classification systems and to test hypotheses of the River Continuum Concept. High positive correlations were found between stream gradient and the ratio of shredder to collector organisms and between benthic respiration and high ratio of FBOM to CBOM; a high negative correlation was found between P/R ratio and high shredder to grazer ratio. These and other results support predictions of the River Continuum Concept. Ordination analyses of the untransformed biological data and of the total data base resulted in rankings of the variables suggestive of a gradation from those characteristics of low order (1-2) streams to those characteristics of higher orders (4-6). In general, the overall ordination rankings of the stream sites also were suggestive of a low to high order continuum. Correlation of ordination scores of the untransformed biological data with the different physical-chemical variables suggested that precipitation, gradient, and stream length to watershed area best explained the ordination rankings, and that the shredder to collector ratio, shredder to grazer ratio, UBOM to CBOM ratio, FBOM to CBOM ratio, and gross production were the most influential biological variables. Findings suggest that streams are best viewed as gradients, or continua, and that classification systems which separate discrete reaches are of little ecological value. (Author's abstract)

THE IMPORTANCE OF ATTACHMENT TO PARTICLES FOR PLANKTONIC BACTERIA,
Universidad Autonoma de Barcelona (Spain). Dept. de Microbiologia.
C. Pedros-Alio, and T. D. Brock.
Archiv fur Hydrobiologie, Vol. 98, No. 3, p 354-379, November, 1983. 5 Fig, 6 Tab, 93 Ref.

Descriptors: *Plankton, *Bacteria, *Particles, *Bacterioplankton, Epilimnion, Biomass, Sedimentation, Hydraulic flushing, Zooplankton, Lake Mendota, Wisconsin.

The importance of attachment to particles for heterotrophic bacteria in the epilimnion of Lake Mendota, Wisconsin, was analyzed. Attached bacteria constituted from 1% (in winter) to 30% (in summer) of the total cell counts obtained by epifluorescence. When biomass was calculated from counts and volumes measured in scanning electron micrographs, attached bacteria contributed up to 50% of the total biomass. Three indicators of bacterial activity were measured separately for attached and freeliving bacteria: frequency of dividing cells (FDC), dark sulfate uptake, and acetate uptake. Attached bacteria were bigger, had higher FDC, and were responsible for most of the acetate uptake. Free-living bacteria were smaller with lower FDC, and responsible for most of the sulfate uptake. Using this information and results from other studies, hydraulic flushing of the system, abundance of particles, sedimentation, and feeding by zooplankton were considered to be the most important factors in regulating what percent of the bacterioplankton activities and biomass is due to attached bacteria in a given system. CALCITE PRECIPITATION AS A NATURAL CONTROL MECHANISM OF EUTROPHICATION,
Zentralinstitut fur Mikrobiologie und Experimentelle Therapie der Akademie der Wissenschaften der DDR, Jena. Abt. Limnologie.
R. Koschel, J. Benndorf, G. Proft, and F. Recknagel.
Archiv fur Hydrobiologie, Vol. 98, No. 3, p 380-408, November, 1983. 15 Fig, 5 Tab, 58 Ref.

Descriptors: *Calcite precipitation, *Eutrophication, *Lake Breiter Lucin, *East Germany, Phosphorus, Phytoplankton, Light transmission, Algae, Flocculation, Model studies.

The observations of calcite precipitation in the deep mesotrophic Lake Breiter Lucin (Germany, D.R.) indicated that calcite precipitation is connected with a decrease in dissolved and total phosphorus, phytoplankton biomass and light transmission. Additional investigations in other lakes of the same geographical region show that the maximum of calcite in the sinking material is found 2 to 4 weeks after the maximum of primary production of phytoplankton. The calcite content of the profundal sediments exhibits high values in eutrophic especially in mesotrophic lakes and small values in oligotrophic lakes. All the observations show that calcite precipitation must be linked with a control mechanism which acts as a natural self-protection of the lakes against eutrophication. The most probable hypotheses to answer the question, why calcite precipitation acts as a control mechanism of lake eutrophication, were specified as scenarios and checked by means of the dynamic ecological model SALMO. From the scenario analysis the conclusion can be drawn only that self-flocculation of the algae is the dominating mechanism which is responsible for the self-protection of these lakes against eutrophication. LIGHT ATTENUATION IN ONONDAGA LAKE, NY, USA, 1978,
Louisiana State Univ., Baton Rouge. Dept. of Civil Engineering.
S. D. Field, and S. W. Effler.
Archiv fur Hydrobiologie, Vol. 98, No. 4, p 409-421, November, 1983. 5 Fig, 1 Tab, 31 Ref.

Descriptors: *Light penetration, *Lakes, Lake Onondaga, New York, Algae, Phytoplankton, Eutrophication, Light intensity, Productivity.

The partitioning of attenuation of photosynthetically active radiation (PAR) between the phytoplankton of Onondaga Lake and their environment was evaluated for 7 months. The estimates of the attenuation coefficients for chlorophyll-a, k(c), and for water and its nonphytoplankton components were within the range reported in the literature. The phytoplankton of the lake were dominated by chlorophytes. The phytoplankton failed during the study period to reach levels at which self-shading would be a significant influence. One hundred and eighteen parallel observations of light attenuation and chlorphyll-a were included in the analysis. These attenuation characteristics, in combination with the observed chlorophyll-a levels, are interpreted with respect to their influence on the relative rate of integral photosynthesis within the lake. The critical role the assessment of these characteristics plays in the calibration of a phytoplankton productivity model for the lake is described. (Baker-IVI)

DIEL OXYGEN VARIATIONS AND THEIR ECOLOGICAL IMPLICATIONS IN AMAZON FLOODPLAIN LAKES,
California Univ., Santa Barbara. Dept. of Biological Sciences.
J. M. Melack, and T. R. Fisher.
Archiv fur Hydrobiologie, Vol. 98, No. 4, p 422-442, Stuttgart, November, 1983. 13 Fig, 1 Tab, 33 Ref.

Descriptors: *Dissolved oxygen, *Diel variations, Mixing, Nutrients, Lago Calado, Brazil, Amazon floodplain, Photosynthesis, Epilimnion, Hypolimnion, Phosphates, Ammonium, Organic matter.

Eighty diel cycles of dissolved oxygen were measured during a sixteen month period in Lago Calado, an Amazon floodplain lake. While planktonic photosynthesis is modest, air-water exchanges, vertical mixing and perhaps advection can strongly influence diel oxygen variations. Influx of oxygen from the atmosphere is a major source of dissolved oxygen. A conspicuous feature of oxygen content is erratic variation between periods of positive or negative rates of oxygen change during both day and night. An important implication of the episodes of vertical mixing indicated by the dissolved oxygen variations is the injection of nutrients such as phosphate and ammonium from the hypolimnion into the epilimnion. Diffusion-corrected, daytime changes in oxygen content clearly indicate that on most days the net dissolved oxygen change is negative. The main implication of this result is that the biota of Lago Calado consumes more organic matter than is produced autochthonously.

THE SEASONAL VARIATION OF ORGANIC CONSTITUENTS IN A EUTROPHIC LAKE, LAKE SUWA, JAPAN; PART II. DISSOLVED ORGANIC MATTER,
Nagoya Univ. (Japan). Water Research Inst.
T. Hama, and N. Handa.
Archiv fur Hydrobiologie, Vol. 98, No. 4, p 443-462, Stuttgart, November, 1983. 11 Fig, 40 Ref.

Descriptors: *Eutrophic lakes, *Lake Suwa, *Japan, *Dissolved organic matter, Carbohydrates, Proteins, Amino acids, Acetic acid, Diatoms, Microcystis, Seasonal variation, Phytoplankton.

Water samples were collected from Lake Suwa, one of the most eutrophic lake in Japan, once a month from April, 1979 through August, 1980 and analyzed for dissolved organic carbon, carbohydrates, protein (including amino acids) and acetic acid. The molecular weight distribution of dissolved organic matter (DOM) in each of the water samples was also tested by the gel-filtration technique. Dissolved organic carbon (DOC) concentrations ranged from 1.4 to 3.4 mg C/L, and varied seasonally in close relation to the seasonal change in the standing stock and species composition of phytoplankton. Diatom and Microcystis aeruginosa had a great influence over the concentration of DOC in this lake. Seasonal distribution profiles of dissolved carbohydrates, protein and acetic acid differed little from that of DOC. Polysaccharides consisting of glucose, galactose, xylose, and rhamnose and of galactose, rhamnose and fucose were found in the water samples when M. aeruginosa and diatom blooms occurred respectively. Extracellular production of polysaccharide(s) by phytoplankton was evidenced. There were seasonal changes in molecular weight distribution of dissolved carbohydrates and proteins. Poly- and oligosaccharides were key substances determining the concentration of dissolved carbohydrate in this lake, while all components of the proteinous materials changed their concentration irrespective of molecular weight. THE GEOCHEMICAL RECORD OF MAJOR CATIONS AND TRACE METALS IN A PRODUCTIVE LAKE; ANALYSIS OF THINLY SLICED SEDIMENT SAMPLES CHARACTERISED BY DIATOM STRATIGRAPHY,
Freshwater Biological Association, Ambleside (England).
U. Ochsenbein, W. Davison, J. Hilton, and E. Y. Haworth.
Archiv fur Hydrobiologie, Vol. 98, No. 4, p 463-488, Stuttgart, November, 1983. 6 Fig, 6 Tab, 51 Ref.

Descriptors: *Geochemistry, *Trace metals, *Diatoms, *Sediments, Minerals, Heavy metals, Water pollution sources, Lead, Cadmium, Zinc, Stratigraphy, Blelham Tarn, England.

The concentration-depth behavior of Mg, K, Al, Fe, Mn, Cu, Ni, Zn, Cd, Pb, C, percentage mineral matter and water content of a sediment core from Blelham Tarn, a small productive lake in the English Lake District, was examined at 0.5 intervals over a 600 year period. Detailed algal stratigraphic evidence suggested that the supply of all elements is free from large annual fluctuations. Peaks in the concentration of carbon, iron and other trace metals were tentatively attributed to an inflow of humic material. X-ray diffraction analysis of the minerals showed that leaching of Mg from chlorite has not played a significant role in its recruitment to the sediments. Mg, K, Al, Fe and Ni were largely of mineralogical origin. The profile shapes of organic carbon and manganese are related and can be rationalized in terms of the rapid redox cycling of manganese at the sediment-water interface. Pb, Cd and Zn all show elevated concentrations, which systematically decrease during the past 10 years. Consideration of fluxes indicates that this pollution can not be accounted for by direct deposition of air-borne metal onto the lake surface. Elevated anthropogenic Pb concentrations appear before the equivalent increase in other metals. (Author's abstract)

COMPOSITIONAL CHANGES OF FATTY ACIDS IN PARTICULATE MATTER AND WATER TEMPERATURE, AND THEIR IMPLICATIONS TO THE SEASONAL SUCCESSION OF PHYTOPLANKTON IN A HYPEREUTROPHIC LAKE, LAKE KASUMIGAURA, JAPAN
Tsukuba Univ., Ibaraki (Japan). Inst. of Biological Sciences.
T. Miyazaki.
Archiv fur Hydrobiologie, Vol. 99, No. 1, p 1-14, December, 1983. 6 Fig, 31 Ref.

Descriptors: *Fatty acids, *Lakes, Japan, Lake Kasumigaura, Eutrophication, Seasonal variations, Phytoplankton, Temperature effects, Water temperature, Particulate matter, Sediments.

Seasonal succession of phytoplankton in lake ecosystems takes place through interactions of physical, chemical, and biotic factors. Temperature, among others, affects many biochemical reactions of phytoplankton, and is one of the most important factors in understanding mechanisms of the seasonal succession. Fatty acids were considered to originate from phytoplankton because of a good correlation between the amounts of fatty acids and chlorophyll-a. The percentage of unsaturated fatty acids showed a remarkable relation to water temperature: the percentage was higher and constant at lower temperatures and decreased to about 40% as temperature increased to 28 degrees C. However, this percentage had no correlation with the amount of inorganic nitrogen. These findings suggest that water temperature played an important role in determining the percentage of unsaturated fatty acids in phytoplankton. Moreover, fatty acid composition and chlorophylls-b and c varied correspondingly, reflecting the change in phytoplankton species throughout the year. (Baker-IVI)

DEGRADABILITY OF DISSOLVED ORGANIC LAKE WATER COMPOUNDS IN CULTURES OF NATURAL BACTERIAL COMMUNITIES
Konstanz Univ. (Germany, F.R.). Limnologic Inst.
A. Geller.
Archiv fur Hydrobiologie, Vol. 99, No. 1, p 60-7 December, 1983. 8 Fig, 3 Tab, 30 Ref.

Descriptors: *Dissolved solids, *Biodegradatio *Bacteria, Lakes, Chemical properties, Dissolve organic carbon, Microbial degradation.

Dissoved organic matter in lakes is mainly com posed of a range of oligomeric to macromolecul compounds derived from autochthonous produ tion and allochthonous input. Ninety percent dissolved organic carbon (DOC) of Mindelsee co sisted of macromolecular (MW > or = 1500) ar oligomeric (MW 400-800) components which we isolated during the four seasons. The compoun were subjected to degradation by natural bacteri communities present in the lake at the same tim Regardless of season the lake water constituen were largely resistant to microbial attack duri

the three months incubation period in four of five experiments as shown by DOC measurements. Refractory macromolecules and oligomers depressed growth of bacteria as established by the microcolony method. Less persistent macromolecules found in one of the experiments, consisted of minor constituents which were utilized by various bacteria and a remainder which was decomposed only by specialists forming characteristic microcolonies. Accompanying oligomers consisted of 40%-50% of readily degradable substances and of a remainder, which was inaccessible to the major part of the bacteria. (Murphy-IVI)

GROWTH KINETICS OF MICROCYSTIS AERUGINOSA (KUTZ) KUTZ AS A BASIS FOR MODELLING ITS POPULATION DYNAMICS,
Humboldt-Univ. zu Berlin (German D.R.). Sektion Biologie.
A. Nicklisch, and J.-G. Kohl.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 3, p 317-326, 1983. 1 Fig, 4 Tab, 33 Ref.

Descriptors: *Algal growth, *Population dynamics, *Lakes, *Microcystis, Growth, Kinetics, Eutrophication, Nutrients, Temperature effects, Light intensity, Water quality, Algae.

The dependence of the specific growth rate of Microcystis aeruginosa (Kutz) Kutz f. aeruginosa upon temperature and light intensity was determined under continuous illumination by the analysis of the exponential growth period in batch cultures. Light dependence at the optimum temperature is well described by Michaelis-Menten kinetics. The maximum specific growth rate decreases with decreasing temperature, but the initial slope of the curve does not change, although the flexure of the light dependence curve increases. Therefore, the light dependence at lower temperatures is better described by the model of Smith. The Kf values for the light dependence curves decrease with temperature in about the same manner as the maximum specific growth rates. The temperature dependence of the specific growth rate up to the optimum is well described by a sigmoid curve. The results regarding the interaction between temperature and light can be described by combining the light and temperature dependence. The Ks values for orthophosphate, nitrate and ammonium were determined at 25 degrees C and 24 W/sq m light intensity by measuring the steady state nutrient concentrations of nutrient limited chemostat cultures at a dilution rate of 0.5 micromax. The values obtained characterize M. aeruginosa as an alga of eutrophic waters which reaches high growth rates at even moderate phosphate and nitrate concentrations. (Baker-IVI)

THE RELATIONSHIP BETWEEN NUTRIENT AVAILABILITY, SHOOT BIOMASS AND SPECIES RICHNESS IN GRASSLAND AND WETLAND COMMUNITIES,
Utrecht Rijksuniversiteit (Netherlands). Dept. of Landscape Ecology and Nature Management.
J. G. Vermeer, and F. Berendse.
Vegetatio, Vol. 53, No. 2, p 121-126, September, 1983. 2 Tab, 29 Ref.

Descriptors: *Wetlands, *Grasslands, *Biomass, Nutrients, Moisture availability, Eutrophication, Fens.

A possible relationship between shoot biomass, nutrient concentration in the soil and number of species per unit area was studied in two different parts of the Netherlands: the Gelderse Vallei and the Westbroekse Zodden. Samples were taken of four series of vegetation and soil studies. One series was located in grassland and wetland communities, one in grassland communities, one in fen communities and one series in only one wetland community. The two series in grassland communities showed a negative correlation between shoot biomass and nutrient concentration in the soil. The opposite was found in the series in the fen communities: there was a positive correlation between species number and shoot biomass and a negative correlation between shoot biomass and nutrient concentrations. The series of samples that had been taken in only one wetland community showed an optimum curve for the relation between shoot biomass and number of species. In the plant communities studied the species richness per unit area increases with increasing productivity at low production levels of less than 400-500 g/sq m, and decreases with increasing productivity at higher production levels greater than 400-500 g/sq m. It is possible to construct an optimum curve for the relationship between species number per unit of area and shoot biomass from these findings. However, the optimum can be expected to differ from one plant community to another. (Baker-IVI)

THE DERIVATION AND VALIDATION OF A NEW MODEL FOR THE INTERCEPTION OF RAINFALL BY FORESTS,
Oregon Univ., Eugene. Dept. of Biology.
W. J. Massman.
Agricultural Meteorology, Vol. 28, No. 3, p 261-286, 1983. 3 Fig, 3 Tab, 44 Ref. NSF Grant DEB 80-07542.

Descriptors: *Rainfall, *Forests, Canopy, Model studies, Forest hydrology, Mathematical equations, Storms, Precipitation, Vegetation effects, Evaporation, Interception, Drainage, Water loss, Interception loss.

A dynamic model and an analytical model derived from it can predict the gross interception of forest canopies. The dynamic model is validated using a running balance in time between rainfall, throughfall, evaporation and changes in the canopy storage. The canopy storage is increased by rainfall interception and depleted by evaporation and drainage. The evaporation rate varies with the amount of water in the canopy and is estimated by numerical methods because sufficient meteorological data is not available. Drainage rate expressions are shown to be inadequate during the period of rainfall. A new drip expression which explicitly includes the rain rate, in addition to the stored water, is proposed and tested and found to fit the observed drip rate better, giving significantly better model prediction with fewer empirical parameters than the exponential form of drip rate. The dynamic model was simplified to an analytical model for predicting the gross interception loss. This analytical expression is easier to use as it is not sensitive to the exact value of the drip parameters. It predicted the total observed gross interception loss for the 20 storms tested to within 4%. The new drip expression is recommended for use in the dynamic model as it described better the dislodgement of peviously intercepted rain droplets by falling rain droplets. A new model for estimating evaporation rates from forest canopies is also proposed. The evaporation model was derived assuming that the thermal diffusivity is a constant throughout the tree canopy and that the Bowen ratio and other micrometeorological parameters can be suitably averaged over the duration of a rainstorm. WATER STRESS AND WATER-USE EFFICIENCY IN FIELD GROWN WHEAT: A COMPARISON OF ITS EFFICIENCY WITH THAT OF C4 PLANTS,
Indian Agricultural Research Inst., New Delhi. Water Technology Center.
P. K. Aggarwal, and S. K. Sinha.
Agricultural Meteorology, Vol. 29, No. 3, p 159-167, 1983. 3 Fig, 1 Tab, 26 Ref.

Descriptors: *Water stress, *Plant growth, *Water use efficiency, Wheat, Canopy, Evaporation, Drought, Irrigation, Regression analysis, Statistical studies.

Breeding for water-use efficiency (WUE) is an important objective for the improvement in grain yield of crops grown in rain-fed areas. Water-use efficiency can be improved by either reducing the water use or increasing the dry matter production. Two cultivars of wheat, contrasting in their drought resistance characteristics, were grown under irrigated and non-irrigated conditions in the field for two seasons. The WUE ranged from 0.5 to 13.8 g dry matter/kg water used depending upon the growth stage, cultivar and water stress. The average WUE for the season was between 3.34 and 4.70 g dry matter/kg water used. Regression analysis indicated that WUE was a function of dry matter produced and had no direct statistical relationship with the weather parameters. The WUE of plants having the C3 system of photosynthesis, like wheat, need not be poorer than that of plants with the C4 system, if comparisons are made of plants growing in their respective preferred ecological niches. The observed values of WUE in these experiments would be higher still if the weight of roots and loss of water by evaporation were also considered. One possible reason for the difference between these observed values and the reported values of WUE in the literature is that, under conditions of solution cultures or in pots maintained at field capacity, in the absence of canopy effects, a greater vapour pressure gradient would be established between the evaporating surfaces (leaves and soil) and the atmosphere resulting in excessive water loss without any concomitant increase in dry matter production. (Baker-IVI)

WATER BALANCE OF THREE IRRIGATED CROPS ON FINE-TEXTURED SOILS OF THE RIVERINE PLAIN,
Commonwealth Scientific and Industrial Research Organization, Griffith (Australia). Div. of Irrigation Research.
W. K. Mason, W. S. Meyer, R. C. G. Smith, and H. D. Barrs.
Australian Journal of Agricultural Research, Vol. 34, p 183-191, 1983. 5 Fig, 3 Tab, 29 Ref.

Descriptors: *Hydrologic budget, *Irrigation, *Soil texture, *Riverine Plain, Maize, Sorghum, Sunflower, Plant growth, Moisture uptake, Capillary conductivity, Crop yield, Soil-water-plant relationships.

Since irrigation from the Murray and Murrumbidgee rivers began on the Riverine Plain of south-eastern Australia, agricultural production has gradually intensified and the amount of water used has increased. Three summer crop species, maize, sorghum and sunflower were grown on three different fine-textured soils of the Riverine Plain in south-eastern Australia. At each site, above-ground growth, phenological development, and root length density were measured in two well-watered plots to determine the water requirements of the plants. Water use, plant water status and final crop yield were measured in the well-watered plots and in one plot per site where irrigation was discontinued around the time that complete crop canopies had developed. Plant available water was estimated from these drying-cycle plots. Crop water use calculated from soil water contents did not agree with estimates from a water balance model at two of the sites, suggesting that capillary rise from shallow water tables was supplying considerable quantities of water to the crops. Using the water balance model to predict actual evapotranspiration (E sub t), after complete canopy development, up to 40% of E sub t, was supplied to well-watered crops from a water table at approximately 1.5 m. At the site without a water table, yields from the drying-cycle plots were severely reduced and the estimate of plant available water (PAW) was thought to be realistic. Where capillary rise or lateral movement of water into the root zone was significant, the concept of plant available water (PAW) was unsatisfactory. (Murphy-IVI)

PERENNIAL RYEGRASS GROWTH, WATER USE, AND SOIL AERATION STATUS UNDER SOIL COMPACTION,
Kansas State Univ., Manhattan. Dept. of Horticulture.
K. J. O'Neil, and R. N. Carrow.

Agronomy Journal, Vol. 75, No. 2, p 177-180, March-April, 1983. 5 Tab, 24 Ref.

Descriptors: *Perennial Ryegrass, *Plant growth, *Water use, *Soil aeration, *Soil compaction, Soil physical properties.

Soil compaction is a serious problem on recreational turfgrass sites because the altered soil physical properties can adversely affect plant growth and irrigation management. Soil compaction was examined in a greenhouse study for its effect on turfgrass growth, water use, and soil aeration using a Chase silt loam soil (fine, montmorillonitic, mesic, Aquic Arquidolls). Perennial ryegrass (Lolium perenne L. 'Derby') was subjected to three compaction levels: 1) none-no compaction, 2) moderate-360 joules energy, and 3) heavy-720 joules energy. The soil was compacted by dropping a 11.5 kg weight from a height of 65 cm. When tenslometers (installed at a depth of 5 cm) read-0.65 bar, 5 cm of water was applied. Pots were 30.5 cm I.D. by 76.2 cm long PVC pipe with bottom drainage. Soil compaction increased bulk density; reduced aeration porosity, visual quality, and shoot density; altered root distribution, and reduced root density in the 10 to 25 cm soil zone. It had, however, slight effect on verdure and individual shoot weight. Total clipping weights were reduced by 38 and 53% for the moderate and heavy compaction treatments, respectively. Clipping yield decreased immediately after compaction treatment, while root changes were not apparent until after 12 weeks. Water use was reduced by 21 and 49% for the moderate and heavy compaction treatments, respectively. Water extraction from the 10 to 25 cm soil zone decreased from 69 to 27% of the total water extracted in the heavy compacted pots by the end of the study. With heavy compaction, oxygen diffusion rates (ODR) were below 20 x ten to the minus 9th power g/sq cm/min for at least 53 hours after irrigation. The noncompacted soil achieved acceptable ODR within 5 hours. The combined effects of compaction reducing rooting, slowing shoot growth, and increasing moisture retention, caused the compacted soil to remain at a reduced aeration status longer than the noncompacted soil after irrigation. ROOT DISTRIBUTION AND WATER USE EFFICIENCY OF ALFALFA AS INFLUENCED BY DEPTH OF IRRIGATION,
Mississippi State Univ., Mississippi State. Dept. of Agronomy.
F. Jodari-Karimi, V. Watson, H. Hodges, and F. Whisler.
Agronomy Journal, Vol. 75, No. 2, p 207-211, March-April, 1983. 3 Fig, 3 Tab, 18 Ref.

Descriptors: *Root distribution, *Water use efficiency, *Alfalfa, *Irrigation, Irrigation effects, Irrigation efficiency, Moisture availability, Moisture stress, Evapotranspiration.

Root distribution of several crop plants is affected by different patterns of soil moisture. In alfalfa (Medicago sativa L.), however, such results have not been consistently obtained under field conditions. The effect of different irrigation depths on alfalfa water use efficiency, water extraction patterns, and root distribution under greenhouse conditions where examination of the entire root systems was possible could reveal effective and efficient means for irrigating alfalfa. 'Climmaron' alfalfa was planted in polyvinylchloride (PVC) containers (120 x 30 cm) filled uniformly with a Leeper fine (fine, montmorillonitic, nonacid, thermic Vertic Haplaquept) sandy loam top soil. Irrigation treatments included: watering to saturate the soil one-third of the whole root depth, watering to saturate the soil two-thirds of the whole root depth, and no irrigation. Irrigation was applied when available soild moisture content within the root zone reached 35% (-2.5 bars soil matric potential). The parameters studied included root distribution pattern, total root growth, water extraction pattern, and water use efficiency. The efficiency of water use was higher in deeply irrigated treatments than in shallow irrigated treatments during June and July (a period of high evapotranspirational demand), but it was not different during September to November. Depth of irrigation did not affect total root production, but it did affect root distribution at the irrigation zone. Deeply irrigated plants produced slightly more roots in the lower depths than shallow irrigated plants. Root production of nonirrigated alfalfa was low under the high evaporational demand conditions which occurred during June and July, but was highest among all treatments during the September to November growing period. Root:shoot ratios of 0.28, 0.22 and 0.62 observed in shallow, deep, and non-irrigated plants grown in the September to November period, respectively, indicate that the rate of root growth was increased in nonirrigated alfalfa as a result of limited water stress and under low evapotranspirational demand. WHEAT DEVELOPMENT AS AFFECTED BY DEFICIT, HIGH FREQUENCY SPRINKLER IRRIGATION,
Agricultural Research Service, Prosser, WA.
A. N. Hang, and D. E. Miller.
Agronomy Journal, Vol. 75, No. 2, p 234-239, March-April, 1983. 5 Fig, 4 Tab, 17 Ref. Washington State Univ. Coll. of Agriculture Research Center project 0481.

Descriptors: *Wheat, *Water deficit, *Sprinkler irrigation, Irrigation effects, Water stress, Plant growth, Soil types, Loam, Evpotranspiration.

An important limitation to wheat production worldwide is insufficient water. Therefore, it is important to know how the crop responds physiologically to water stress. Variable irrigation treatments were initiated at pre-or early-boot stage of Fielder spring and Nugaines winter wheat (Triticum aestivum L. em. Thell.) grown on sandy (mixed, mesic, Xeric Torripasamments) and loam (coarse-silty, mixed, mesic Xerollic Camborthids) soils. Different amounts of irrigation water were applied by the line source technique. Daily irrigation near the line source was equivalent to 1.00 (loam) or 1.15 (sand) times estimated evapotranspiration (ET). Pan evaporation (EP) estimated ET as ET = 0.95 EP. On sandy soil, stress symptoms were first observed in plants receiving the least irrigation water (23% estimated ET) 2 weeks after treatments were initiated. Symptoms included decreased number of green leaves, shorter plants, fewer heads, increased specific leaf weight and increased leaf-stem dry weight ratios. Head growth rates were from 8.2 to 15.6 mg/head/day, at the lowest and highest applications, respectively. Reproductive growth rate, crop growth rate, and partitioning to reproductive growth increased with increased irrigation. Effects of decreased irrigation were less on loam soil than on sandy soil. Stress symptoms did not appear until late in the growing season. There were significant differences in plant height, total plant weight, and head weight between the plots receiving highest and lowest irrigation rates (100 vs. 20% estimated ET). Results indicate that normal growth and yield of wheat grown on sandy soil require irrigations that approach ET. However, on loam soil irrigation amounts can be decreased 40 to 50% without affecting developing of plant parts. (Murphy-IVI)

IRRIGATION REGIME EFFECTS ON SOME PHYSIOLOGICAL RESPONSES OF POTATO,
Agricultural Research Organization (Israel). Gilat Regional Experiment Station.
D. Shimshi, J. Shalhevet, and T. Meir.
Agronomy Journal, Vol. 75, p 262-267, March-April, 1983. 5 Fig, 3 Tab, 16 Ref.

Descriptors: *Irrigation program, *Irrigation effects, *Physiological ecology, *Potato, Water stress, Leaf permeability, Leaves, Evapotranspiration, Trickle irrigation, Plant water potential.

Potato is relatively sensitive to water stress, and therefore indices for characterizing the degree o water stress and its relation to tuber yield ar sought. During a series of field irrigation experi ments on potatoes (Solanum tuberosum L.) con ducted on a calcic haploxeralf in the Negev regio of Israel, data were collected on leaf permeabilit (LP), leaf and tuber water potential (psi sub l an psi sub t, respectively) and photosynthetic rate with the aim of relating the variables to a range o water stresses caused by the ratio irrigation/evapo ration (K sub p). Leaf permeability was linearl related psi sub l, which ranged from -0.7 kJ/kg i well irrigated plants to -1.4 kJ/kg in severel water-stressed plants. Tuber water potential, ps sub t, was higher by 0.4 to 0.7 kJ/kg than psi sub l the difference increasing with water stress. I trickle-irrigated plants psi sub l of tubers growin in dry soil was lower by 0.06 to 0.12 kJ/kg than ps sub t of tubers growing in wet soil, even thoug the tubers were attached to the same stem. Photo synthesis increased with LP up to 0.8 mg CO2/s m/sec and declined with plant age independentl of LP. Marketable yield was well related to bot seasonal LP and psi sub l; all three variables de creased when K sub p dropped below 1.0. Lea permeability seems to be a better index than lea water potential for the characterization of wate stress of potato in the field. (Author's abstrac

FIELD EVALUATION OF A WATER RELA TIONS MODEL FOR SOYBEAN. I. VALIDIT OF SOME BASIS ASSUMPTIONS,
B. Zur, J. W. Jones, and K. J. Boote.
Agronomy Journal, Vol. 75, p 272-280, March April, 1983. 6 Fig, 1 Tab, 17 Ref. USDA gra 801-15-58.

Descriptors: *Field tests, *Model studies, *Soy bean, Water potentials, Stomatal transpiratio Moisture profiles, Drying.

Basic assumptions made in a model of stomat feedback control, transpiration, and carbon dioxid exchange rate (CER) were tested on soybean (Gly cine max L. Merr cv. Williams) grown in the fie on an Arredondo fine sand soil. Intensive measur ments were made of diurnal fluctuations in le water potential, stomatal resistance, transpiratio rate (TR), and canopy CER during a drying cyc corresponding to the mid-to-late pod-filling perio of the crop. A threshold leaf water potential initia ing stomatal closure at -1.6 MPa was measured the field and verified the relationship assumed the model. Linear relationships between transpir tion rate and both radiation flux and vapor pre sure deficit were found to exist only in well-w tered plants having low stomatal resistances (1 to sec/cm). Following the time when stomatal cl sure was initiated, the dependence of transpiratio rate on climatic variables quickly dissipated. Tra spiration rate was independent of stomatal resis ance for fully open stomata, quickly decrease following stomata closure and remained essential constant at high stomatal resistance. This overa behavior was satisfactorily described by a modifie Penman equation which includes a stomatal resis ance term. A curvilinear relationship betwe CER and photosynthetically active radiation flu (PAR) existed as long as stomata were fully ope Following stomata closure, CER was independe of PAR above 500 microE/M2.sec (full sunlight 2,100 microE/m2.sec). The dependence of CER stomatal resistance was similar to that of transpir tion rate but with greater sensitivity. (Autho abstract)

FIELD EVALUATION OF A WATER REL TIONS MODEL FOR SOYBEAN, II. DIURNA FLUCTUATIONS,
Florida Univ., Gainesville. Dept. of Agricultur Engineering.
J. W. Jones, B. Zur, and K. J. Boote.
Agronomy Journal, Vol. 75, No. 2, p 281-28 March-April, 1983. 10 Fig, 7 Ref. DA grant 80 15-58.

Descriptors: *Field tests, *Model studies, *Diurnal distribution, Water potentials, Plant water potential, Transpiration, Drying, Soil-water-plant relationships, Soil physical properties.

A field study was conducted on soybeans (Glycine max L. Merr. cv. Williams) growing in Arredondo fine sand, a member of the hypothermic, coated family of Typic Quartzipsamments to determine the effects of drying cycles on plant water relations for comparison with results predicted by a dynamic model. Two different drying cycle treatments were imposed on different plots during late vegetative development and mid-to-late pod fill stages and well irrigated plots were maintained for comparison. Every other day during each drying cycle, hourly measurements of leaf water potential, canopy carbon exchange rate (CER), and canopy transpiration were measured on dry and wet plots. During the initial phases of the drying cycles leaf water potential, transpiration, and CER followed diurnal cycles closely related to radiation flux. This response lasted for 9 and 5 days during the first and second drying cycles, respectively, when crop water deficits reached critical levels causing leaf water potentials of -1.4 and -1.7 MPa. After these critical time periods, midday leaf water potentials became relatively stable with time whereas transpiration and CER decreased such that diurnal fluctuations disappeared. The model was successful in simulating diurnal patterns of these variables for the crop exposed to the two drying cycles. (Author's abstract)

ALFALFA RESPONSES TO IRRIGATION TREATMENT AND ENVIRONMENT,
Agricultural Research Service, Riverside, CA. Salinity Lab.
T. J. Donovan, and B. D. Meek.
Agronomy Journal, Vol. 75, p 461-464, May-June, 1983. 6 Fig, 1 Tab, 18 Ref.

Descriptors: *Alfalfa, *Irrigation effects, Irrigation requirements, Water management, Plant water potential, Crop yield, Evapotranspiration, Water use efficiency.

Water management is critical for maximum production of alfalfa (Medicago sativa L.) with under irrigation resulting in loss of production and over irrigation resulting in a loss of stand. To determine the optimum irrigation rates under high evaporative demand growth of alfalfa was evaluated on replicated plots (6 X 6 m) established on a fine textured soil (Typic Torrifluvent, clayey over loamy, montmorillonitic, calcareous hyperthermic family) and differentially irrigated from July 1975 to January 1978. The irrigation treatments were applied at 56, 66, 75 (best estimate of Et), and 84% of pan evaporation (Ep) and described as dry, semidry, optimum and wet, respectively. Alfalfa yields increased with increase in water applied. Irrigation at 84% Ep for leaching did not enhance yield over the optimum water treatment possibly because of reduced stand from waterlogging. The protein concentration of alfalfa was higher in dry than in wet treatments in March and November. During the summer, plant temperatures in the dry treatment were up to 7 C higher than in the wet treatment. (Murphy-IVI)

TURFGRASS GROWTH, N USE, AND WATER USE UNDER SOIL COMPACTION AND N FERTILIZATION,
Kansas State Univ., Manhattan. Dept. of Horticulture.
M. J. Sills, and R. N. Carrow.
Agronomy Journal, Vol. 75, p 488-492, May-June, 1983. 4 Tab, 22 Ref.

Descriptors: *Plant growth, *Nitorgen, *Water use, *Soil compaction, *Fertilization, Water use efficiency, Plant water potential, Environmental effects, Plant growth substances.

Soil compaction is a problem in many turf areas. Perennial ryegrass (Lolium perenne L. 'Pennfine') was subjected to two compaction treatments with an 11.5 kg falling weight: a) none and b) heavy-874 J energy. Two parts of fine, montmorillonitic mesic, Aquic Argiudoll soil (Chase silt loam) was used to one part medium silica sand by volume. Fertilization rate treatments were 0.5 and 1.0 kg N/100sq m. Nitrogen carrier treatments were water soluble N applied as NH4NO3 and water insoluble N applied as IBDU (isobutylidine diurea). Compaction increased bulk density, water retention, and soil strength, while decreasing aeration porosity. Visual quality, clipping yield, N use per unit area of sod, evapotranspiration, and root growth declined with compaction. Verdure, total nonstructural carbohydrates (TNC), and percent N in leaf tissue were not affected by compaction. Initial TNC levels, water use efficiency, and N use per unit area, increased as N rate increased. Clipping yield, N use per unit area, and water use efficiency were higher with a water-soluble N carrier. Percent N in leaf tissue, early in the study, increased with water-insoluble fertilizer. The most detrimental effects of compaction were on root weight and distribution at the high N rate. Application of high N did not compensate for the adverse effects of compaction. (Murphy-IVI)

WETTING AND MATURITY EFFECTS ON THE YIELD AND QUALITY OF LEGUME HAY,
Wisconsin Univ.-Madison. Dept. of Agronomy.
M. Collins.
Agronomy Journal, Vol. 75, p 523-527, May-June, 1983. 4 Tab, 16 Ref.

Descriptors: *Wetting, *Maturity, *Crop yield, *Legumes, Rainfall impact, Moisture stress, Moisture uptake, Alfalfa, Red clover, Dry matter.

Information is needed on the effects of rain on the magnitude of yield and quality losses of field cured legume hay. Three and one-half kilogram samples of alfalfa and red clover forage grown on Plano silt loam soil (fine-silty, mixed, mesic Typic Argiudoll) and harvested at early and late maturity stages were placed on wire screens and allowed to dry without wetting or were exposed to natural or artificial wetting in 1980 and 1981. A completely randomized design was used with three replications in 1980 and two in 1981. In 1980, 2.5 cm of water was applied to hay wetted during drying. In 1981, hay wetted during drying was exposed to 4.1 and 6.2 cm of precipitation, respectively. Mean dry matter (DM) losses during drying in 1980 were 8.1 and 17.0% from unwetted and wetted forage, respectively, but red clover harvested at the bud stage and wetted lost 25.8% of the total DM. In 1981 unwetted forage, forage wetted during drying and forage wetted after reaching 85% DM lost 10.5, 43.4, adn 53.0% of the initial DM. Wetting did not change forage N concentration greatly in either year. Forage in vitro dry matter disappearance (IVDMD) was reduced by wetting in both years. In 1981 IVDMD was reduced from 66.4% for unwetted hay to 48.1% for hay wetted during drying. Mature forage of alfalfa was lower in IVDMD than bud stage alfalfa in both years regardless of wetting treatment. Neutral detergent fiber concentrations was increased by wetting red clover forage in both years. Prolonged wetting in 1981 reduced the yield of N and TNC by 40.3 and 71.5%, respectively. Dry matter and quality losses due to wetting of legume forage during hay curing vary with legume species and the timing and duration of wetting. Results indicate that plant constituents differ in their susceptibility to loss due to wetting during hay curing. (Murphy-IVI)

INFLUENCE OF WATER STRESS ON THE DIURNAL EXCHANGE OF MASS AND ENERGY BETWEEN THE ATMOSPHERE AND A SOYBEAN CANOPY,
National Oceanic and Atmospheric Administration, Oak Ridge, TN. Air Resources Atmospheric Turbulence and Diffusion Lab.
D. D. Baldocchi, S. B. Verma, N. J. Rosenberg, B. L. Blad, and A. Garay.
Agronomy Journal, Vol. 75, p 543-548, May-June, 1983. 6 Fig, 1 Tab, 40 Ref. Atmospheric Research Division, NSF grant ATM-7901017.

Descriptors: *Water stress, *Diurnal distribution, Mass, Energy, Atmospheric physics, Water use efficiency, Evapotranspiration, Micrometeorology, Carbon dioxide.

A micrometeorological-physiological study at Mead, Nebr., during the summer of 1980 examines the diurnal exchanges of mass and energy of well-watered and water-stressed soybean (Glycine max (L.) Merr. cy. Harosoy) canopies and relates these exchanges to environmental and physiological variables. Measurements of CO2, latent heat and sensible heat flux uses the Bowen-ratio energy balance technique. The soil of the area is a Sharpsburg silty clay loam (a fine, montmorillonitic, mesic Typic Argiudoll). Water stress greatly influenced the partitioning of available energy between latent and sensible heat flux. When the crop was well-watered, sensible heat (H) was directed toward the crop and caused latent heat exchange (LE) to exceed net radiation (Rn). When the crop was water stressed, only two-thirds of Rn was consumed as LE; the remainder was converted into sensible heat. Since both Rn and vapor pressure deficit were greater on the day when the crop was water-stressed, stomatal closure appears to have been the primary cause of the reduction in LE. Carbon dioxide exchange was not sensitive to water stress in the morning but was severely limited by such stress during midday. The midday reduction in CO2 exchange appears to have been caused by a combination of high stomatal resistance limiting CO2 diffusion to the cell chloroplasts and low leaf water potential coupled with high air temperature affecting the enzymatic reactions associated with photosynthesis. Water use efficiency (defined in terms of the CO2-water flux ratio) was greater when the crop was well-watered than when it was stressed for water. A combination of water stress, a large vapor pressure deficit, and high air temperature reduced the CO2-water flux ratio. (Murphy-IVI)

YIELD AND WATER USE EFFICIENCY OF GRAIN SORGHUM IN A LIMITED IRRIGATION-DRYLAND FARMING SYSTEM,
Agricultural Research Service, Bushland, TX. Conservation and Production Lab.
B. A. Stewart, J. T. Musick, and D. A. Dusek.
Agronomy Journal, Vol. 75, p 629-634, July-August, 1983. 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Water use efficiency, *Water yield, *Grain sorghum, *Irrigation, *Dry farming, Net rainfall, Transpiration, Evapotranspiration, Furrow dams, Water management, Soil-water-plant relationships.

A Limited Irrigation-Dryland (LID) farming system, for the conjunctive use of rainfall and limited irrigation of graded furrows, actually adjusts, during the crop growing season, the amount of land irrigated since more land can be irrigated during above-average rainfall years with a limited amount of irrigation water than during below-average years. The design used a limited water supply to irrigate a larger area than could be conventionally irrigated. A graded furrow field, 600 m long on a 0.3 to 0.4% slope was divided into three water management sections. The upper half of the field was managed as 'fully irrigated.' The next one-fourth was managed as a 'tailwater runoff' section that utilized furrow runoff from the fully irrigated section. The lower one-fourth was managed as a 'dryland' section capable of utilizing runoff from either rainfall or irrigation on the wetter sections. The system was field tested for 3 years with grain sorghum (Sorghum bicolor (L.) Moench) on a Pullman clay loam (fine, mixed, thermic family of Torretic Paleustolls). Seasonal rainfall values were 224 mm in 1979, 103 mm in

1980, and 424 mm in 1981 as compared to the average of about 250 mm. The LID system was successful in increasing the utilization efficiency of irrigation water. Irrigation water added to a field can be transpired, evaporated, percolated, lost as runoff, or left stored in the soil after harvest. The LID system tended to reduce all losses other than transpiration. When 125 mm or 185 mm of irrigation water were added with the LID system, the evapotranspiration by grain sorghum was increased by an almost equal amount. This increased grain yield an average of 154 kg/ha for each 10 mm added irrigation, compared to 92 kg/ha for each 10 mm under conventional irrigation practices. (Murphy-IVI)

NITROGEN FIXING ACTIVITY OF WATER STRESSED SIRATRO,
Texas A and M Univ., College Station. Dept. of Range Science.
M. Ismaili, D. D. Briske, and R. W. Weaver.
Agronomy Journal, Vol. 75, p 649-653, July-August, 1983. 4 Fig, 12 Ref.

Descriptors: *Nitrogen fixing, *Water stress, *Siratro, Water potentials, Drought, Soil water potential, Plant water potential, Nitrogen, Soil-water-plant relationships, Leaves.

Siratro 'Macroptilium atropurpureum (DC.) Urb.cv.siratro' is grown in tropical and subtropical environments characterized by frequent periods of drought and is dependent on N2 fixation for its N. Leaf and nodule water potentials to N2 (C2H2) fixing activity and the capability of nodules to recover N2 (C2H2) fixing activity forty-two days after planting four water treatments were imposed by withholding water for increasing periods of time. This created a decrease in leaf and nodule water potentials corresponding to the period of time water was withheld. However, when water potentials decreased below -1.5 MPa, nodule water potentials became more negative than leaf water potentials. A similar decrease in water potential suppressed growth of both nodules and shoots. In the longer duration, water withholding treatments nodule and shoot weights decreased as a result of nodule sloughing and leaf shedding. All water withholding treatments reduced the rate of N2 (C2H2) fixing activity. Nodules with water potentials of -1.5 MPa or greater were able to regain much of their N2 (C2H2) fixing activity within 2 d following rewatering. The specific activity of nodules surviving the most severe level of water stress (-1.9 MPa) were only about 60% as active as the control 6 d following rewatering. Nodules were irreversibly inactivated by water stress more severe than -3.0 MPa but in approximately 12 d following rewatering new nodules developed. Regrowth of siratro following water stress may be delayed while the capacity for N2 fixation recovers. (Murphy-IVI)

EFFECTS OF IRRIGATION ON ACCUMULATION OF SOIL AND SYMBIOTICALLY FIXED N BY SOYBEAN GROWN ON A NORFOLK LOAMY SAND,
Agricultural Research Service, Florence, SC. Coastal Plains Soil and Water Conservation Research Center.
T. A. Matheny, and P. G. Hunt.
Agronomy Journal, Vol. 75, No. 5, p 719-722, September-October, 1983. 1 Fig, 4 Tab, 16 Ref.

Descriptors: *Irrigations effects, *Nitrogen, *Accumulation, *Soil, *Soybean, *Loamy sand, Drought, Water management, Nitrogen fixation, Comparison studies.

In the southeastern Coastal Plain, soybean (Glycine max (L.) Merr.) is normally grown on soils that are often exposed to drought and leaching rains as well as being low in available N. This field study evaluates the impact of water management on accumulation of soil and symbiotically fixed N by soybean grown on these type soils. Nodulating and nonnodulating isolines of 'Lee' cultivar soybean were grown under irrigated and nonirrigated conditions in 1979 and 1980 on a Norfolk loamy sand (fine-loamy, mixed, mesic Typic Paleudults). A period of excessive rainfall occurred in 1979, while a major drought occurred in 1980. Irrigated treatments had lower soil-NO3(-) concentrations in the Ap horizon than nonirrigated treatments during 1979, but there was no effect of irrigation on soil NO3(-) in 1980. Dinitrogen fixation, as estimated by the difference in N accumulation between nodulating and nonnodulating isolines, accounted for 76 to 91% of total plant N in the irrigated plots and 55 to 60% in the nonirrigated plots. Total plant N fixed exceeded 1100 mg/plant for the irrigated plots in 1979 and 1980. Maximum N accumulation for the nodulating isoline occurred in the nonirrigated plots in 1979 and in the irrigated plots in 1980. However, the nonnodulating isoline had maximum accumulations of both N and dry matter in the nonirrigated treatments in both 1979 and 1980. The number of nodules/plant and the C2H2(-) reducing activity were significantly higher in the irrigated plots during the pod growth stages in 1980. Irrigation did not significantly affect seed yield of nodulating Lee soybean in 1979, but did result in a twofold increase in 1980. The effects of irrigation on the Lee nonnodulating isoline resulted in a positive yield response in 1980, but a negative response in 1979. These findings show that a major portion of the N-requirement for soybean in the southeastern Coastal Plain is met by fixation and that the relative importance of fixed N may vary substantially with rainfall patterns and irrigation. SOIL WATER AND POPULATION INFLUENCE ON HYBRID SUNFLOWER YIELD AND UNIFORMITY OF STAND,
North Dakota State Univ., Fargo. Dept. of Soil Science.
L. Prunty.
Agronomy Journal, Vol. 75, p 745-749, September-October, 1983. 3 Fig, 3 Tab, 24 Ref.

Descriptors: *Soil water, *Population, *Sunflower, *Yield, *Stem, Soil water potential, comparison studies, Irrigation effects.

Sunflower (Helianthus annuus L.) hybrids do not respond identically to agronomic and environmental variables. The present study quantifies the influence of soil water potential and plant population on oilseed sunflower hybrids 'Dahlgren 704', 'USDA 894', and 'Interstate 907'. Desire to refind knowledge of yield relationships was one motivation for the study, but a deeper stimulus was the need for basic knowledge of the detailed nature of sunflower stands. One plot site had Maddock (sandy, mixed Udorthentic Haploboroll) and Gardena (coarse-silty, mixed pachic Udic Haploboroll) soils. This location received irrigation treatments limiting soil water potentials to minimums of -35, -70, and -105 J/kg. The second site had Bearden (fine-silty, frigid Aeric Calciaquoll) soil and was not irrigated. Yield increased with soil water potential from 201 g/sq m at -105 J/kg to 284 g/sq m at -35 J/kg. Dryland yields were 200, 179, and 164 g/sq m for hybrids 894, 704, and 907. Population did not influence yields. However, irrigated and nonirrigated stand loss percentages increased with population at 0.8 and 2.2% per plant per square meter, respectively. Knowledge of the threshold population for stand loss provides a rationale for selection of population in the absence of yield differences because significant stand loss indicates a possibly undesirable level of intraspecific competition. Guidelines for irrigation scheduling for sunflower by use of tensiometers are now on a sounder experimental basis. Hybrids similar under irrigation yielded differently under dryland conditions. ALFALFA STEM AND LEAF GROWTH DURING WATER STRESS,
Wisconsin Univ.-Madison. Dept. of Soil Science.
P. W. Brown, and C. B. Tanner.
Agronomy Journal, Vol. 75, p 799-805, July-August, 1983. 6 Fig, 1 Tab, 22 Ref. ARS project 142-1710.

Descriptors: *Alfalfa, *Leaf growth, *Water Stress, Irrigation effects, Leaves, Water potential, Stomata, Soil-water-plant relationships.

Alfalfa (Medicago sativa L.) requires irrigation in semiarid and arid regions and improved yields often result from irrigation in subhumid and humid areas. Despite the importance of optimizing water management for alfalfa leaf and stem growth, no field study has been reported which relates alfalfa leaf expansion or stem extension to plant water deficits. How does leaf expansion, stem elongation, and stomatal response of alfalfa relate to the water potential in alfalfa, field-grown on Plainfield loamy sand (mixed, mesic Typic Udipsamment). Periodic measurements of alfalfa stem extension and leaf expansion (area derived from length and width measurements) were related to leaf water potential (psi L) measured with a pressure chamber, soil matric potential (psi m, measured with tensiometers, and stomatal conductance measured with porometers. For wellwatered alfalfa, expansion curves of individual leaves were sigmoid-shaped, while internode extensions were nearly exponential with time through about 95% of the total extension. The primary leaf attached at the top of an internode expands to nearly full size before the internode begins rapid extension. The growth of individual leaves and internodes collectively results in nearly constant rates of leaf expansion and stem extension during vegetative regrowth. When psi m at 30 cm decreased to -0.35 bar, afternoon psi L decreased to about -8 bars, about 2 bars below irrigated alfalfa, and both the growth rate (GR) and relative growth rate (RGR) of stressed leaves and stems were significantly less ($p < 0.1$) than well-watered leaves and stems. In stressed treatments, wilting, gray-green canopy color, decreased afternoon stomatal conductance, and a 50% decrease in RGR as compared to irrigated treatments resulted when afternoon psi L decreased to about 15 bars even though psi m exceeded -0.1 bar at 90 and 150 cm. Alfalfa extracted 85% of its total water from the 1st meter of soil prior to the onset of decreased afternoon stomatal conductance, but nearly equal percentages from each of the top 2 m of soil afterward. Little shoot growth occurred when psi L dropped below -10 bars. Development of water stress 2 weeks after cutting reduced alfalfa leaf size, internode length, and dry matter production, but not leaf and internode number or stem density. The percentage of total forage dry weight in leaves (LPDW) decreased linearly with stem height resulting in higher LPDW and a better quality forage in stressstunted forage. Cool night temperatures limited growth of well-waterd alfalfa. (Murphy-IVI)

EFFECT OF WIND ON THE CROP WATER STRESS INDEX DERIVED BY INFRARED THERMOMETRY,
California Univ., Davis.
J. C. O'Toole, and J. L. Hatfield.
Agronomy Journal, Vol. 75, p 811-817, September-October, 1983. 6 Fig, 1 Tab, 13 Ref.

Descriptors: *Water stress, *Wind pressure, *Infrared Thermometry, *Temperature, Plant water potential, Canopy, Sorghum, Cotton, Micrometeorology.

A new plant or crop water stress index (CWSI) that depends on interpreting crop or foliage-to-air temperature differential (Tf-Ta) shows promise in both research and irrigation water management. The method relies on the unique relation between Tf-Ta and atmospheric water vapor pressure deficit (VPD). However, the method of estimating the upper limit of Tf-Ta, a critical step in CWSI calculation, was questionable and lacked field validation. The upper limit of Tf-Ta and attendant micrometeorological variables on severely water stressed sorghum (Sorghum bicolor L.), corn (Zea mays L.), and bean (Phaseolus vulgaris L.) grow

on a Typic Xerotherent, and cotton (Gossypium hirsutum L.) grown on a Typic Torriorthent ranged from 2.5 to 8.5C across crops. There was poor agreement between actual and calculated values with respect to net radiation, VPD, and windspeed. Windspeed was found to be the primary factor causing erroneous estimation of the upper limit of Tf-Ta and hence CWSI values. Crop water stress index values measured at low windspeed overestimated the level of water stress while those measured at high windspeed underestimated it. Crop specific changes in the boundary layer resistance-windspeed relationship partially explain the discrepancy between measured and calculated Tf-Ta upper limit values. Modification of the CWSI to account for the influence of windspeed is discussed. (Murphy-IVI)

A METHOD FOR INDUCING CONTROLLED MOISTURE STRESS ON SEEDLINGS,
North Carolina State Univ. at Raleigh. Dept. of Crop Science.
M. Sikurajapathy, J. J. Cappy, and H. D. Gross.
Agronomy Journal, Vol. 75, p 840-843, September-October, 1983. 2 Fig, 3 Tab, 17 Ref. Agency for International Development grant AID/csd 2835.

Descriptors: *Moisture stress, *Seedlings, Soil water, Soil water potential, Soil columns, Water potential, Drought, Rice, Mungbean.

Selectively permeable sleeves filled with soil were held in tanks containing various polyethylene glycol (PEG) 10 000 solutions in order to evaluate seedling tolerance to soil moisture stress. The soil columns, made of 7.6 cm diam dialysis tubing molecular weight (MW) cut off 8000), were fitted to plexiglass bases and placed in tanks containing PEC 10 000 solutions calibrated to provide the desired soil water potentials (-0.01, -0.1, -0.5, and -1.5 MPa). The columns contained 2.5 kg soil. The membrane maintained its integrity over a 30-day period. Soil water moved in response to gradients created by the osmoticum; the small pore size of the permeable sleeves prohibited the PEG from entering the soil. Water loss measured for soil columns immersed in PEG solution maintaining -0.01 MPa potential revealed no movement in either direction. At -0.5 MPa, water moved gradually out of the soil columns. At the lower potentials (-0.01 and -0.1 MPa), rapid movement of water out of the soil occurred within 20 h, leading to a loss of 60% of the water in the columns. Water content at various column depths after 12 and 30 days immersion at the different potentials were very uniform. No detectable amounts of PEG were found in roots, shoots, or leaves of mungbean (Vigna radiata (L.) Wilczek) or rice (Oryza sativa L.). The technique makes possible precise control of water-stress intensity (water potential), water- stress duration, and recovery from water stress. (Author's abstract)

YIELD AND WATER RELATIONS OF PEARL MILLET GENOTYPES UNDER IRRIGATED AND NONIRRIGATED CONDITIONS,
International Crops Research Inst. for the Semi-Arid Tropics, Patancheru (India).
P. Singh, E. T. Kanemasu, and P. Singh.
Agronomy Journal, Vol. 75, p 886-890, November-December, 1983. 1 Fig, 8 Tab, 19 Ref.

Descriptors: *Crop yield, *Water stress, *Pearl millet, *Irrigation effects, Drought, Plant water potential, Leaves, Water use.

Drought resistance in pearl millet (Pennisetum americanum (L.) Leeke) makes it an important food crop in arid and semiarid regions, but research is limited on drought resistance and physiological responses to water stress. To study the relationship of pearl millet yield to physiological characteristics, 10 pearl millet genotypes were grown under irrigated and nonirrigated conditions on a silt loam soil (fine-silty, mixed mesic, Pachic Haplustoll). Leaf diffusion resistance of adaxial (LDRad) and abaxial (LDRab) surfaces, leaf water potential (psi L), leaf osmotic potential (psi pi L) and stem osmotic potential (psi pi s) of genotypes were recorded in both treatments in the afternoon (1200 to 1700 h) when the crop was water-stressed. Leaf diffusion resistance (LDR) for a leaf was calculated as LDR = (LDRad x LDRab)/(LDRad + LDRab). LDRad, LDRab, LDR, psi L, psi pi L, and psi pi s observed for each genotype were averaged over the stress period and correlated with yields and yield ratios (nonirrigated yield/irrigated yield) of genotypes. Majority of genotypes studies did not differ significantly ($P < 0.05$) in average afternoon LDRab, psi L, psi pi L, psi pi s, and water use (WU) in both the treatments except that genotypic differences were significant in average afternoon LDRad and LDR in the nonirrigated treatment. Grain yield was signficantly correlated with LDRab in both irrigated ($r = -0.90$) and nonirrigated ($r = -0.72$) treatments, suggesting that high LDRab of genotypes is associated with low grain yield. Grain yield ratio was significantly correlated with LDRab ($r = 0.71$) and LDR ($r = 0.66$) in the irrigated treatment and with psi L ($r = 0.64$) and psi pi s ($r = .078$) in the nonirrigated treatment. Average afternoon psi L did not correlate with grain yield or grain yield ratio. It is concluded that average afternoon LDRab could be used to rank pearl millet genotypes for their grain yield in both stressed and nonstressed environment. (Author's abstract)

MAGNESIUM NUTRITION AND GRAIN YIELD OF MAIZE HAVING LOW WATER POTENTIAL,
Navarra Univ., Pamplona (Spain). Dept. Fisiologia Vegetal.
P. M. Aparicio-Tejo, and J. S. Boyer.
Agronomy Journal, Vol. 75, p 919-923, November-December, 1983. 5 Fig, 4 Tab, 18 Ref. NSF grant PCM 79-09790.

Descriptors: *Magnesium, *Maize yield, *Plant water potential, Plant growth substances, Leaves.

Drought decreases plant production but the nutritional status of the plants may alter their susceptibility. Losses in the activity of chloroplast coupling factor could be simulated by concerntrations of Mg slightly higher than those usually present in chloroplasts. Since dehydration might increase cellular ion concentrations, it is possible that the photosynthetic response of plants to low water potentials would reflect at least in part the ion status of the tissues. Plants were grown at two soil Mg levels in a controlled environment capable of providing yields comparable to those in the field. The grain yield, shoot and root dry weight, leaf water potential (psi w) and tissue mineral composition were determined. Immediately after tasseling, water was withheld from the soil of half the plants until the psi w had decreased to -1.8 to -2.0 MPa, where it remained until maturity. Low water potentials resulted in a 50% reduction in grain yield and an accelerated leaf senescence. Despite small but significant differences in Mg concentration in roots, stems, and leaves, no differences attributable to differences in Mg nutrition were found in rate of plant dehydration, dry matter accumulation, or grain yield. Differences in Mg content of the plant either do not influence response to low psi w, or must be larger than achieved to see an effect. (Murphy-IVI)

SOYBEAN WATER STATUS AND CANOPY MICROCLIMATE RELATIONSHIPS AT FOUR ROW SPACINGS,
Agricultural Research Service, Florence, SC. Coastal Plains Soil and Water Conservation Research Center.
R. E. Sojka, and J. E. Parsons.
Agronomy Journal, Vol. 75, p 962-968, November-December, 1983. 7 Fig, 1 Tab, 32 Ref.

Descriptors: *Soybeans, *Plant water potential, *Canopy, *Microclimate, *Cultivation, Humidity, Temperature, Moisture availability, Evapotranspiration.

There is little field data relating plant water status and canopy microclimate of determinate soybean 'Glycine max (L.) Merr.' cultivars grown in humid environments. Also, few observations of these parameters have been reported for the period prior to complete canopy closure. A field study in South Carolina in 1979 determines these basic relationships for two determinate soybean cultivars, Davis (Group VI) and Coker 338 (Group VIII) grown in 1.02, 0.76, 0.51 and 0.36-m row spacings. The experiments were conducted on a Norfolk loamy sand (fine-loamy, siliceous, thermic, Typic Paleudult). Thermistor-determined leaf temperatures (T sub L) and ambient temperatures (T sub A) were highly correlated, and no significant improvement in the correlation resulted from treating row spacing or diurnal periods separately. Both T sub L and delta T(T sub L - T sub A) were highly correlated with pressure chamber determination of xylem pressure potential (psi x). Parallel leaf diffusive resistance (Rs) was not highly correlated with any of the canopy microclimate or water status parameters observed. Atmospheric vapor pressure deficit (VPD) was correlated with delta T. Xylem pressure potential was very highly correlated with leaf vapor pressure deficit (LVPD). No row spacing effect on psi x was observed, but mean seasonal midday psi x, was 0.10 MPa lower for Coker 338 than for Davis ($P <$ or $=$ to 0.001) and osmotic potential was 0.20 MPa lower for Coker 338 than for Davis ($P <$ or $=$ to 0.01). The authors propose that the slope of delta T vs. VPD may be influenced by high prevailing relative humidity and heating of the canopy from exposed soil between rows in the period prior to complete canopy coverage. ROOT SYSTEM CHARACTERISTICS OF TWO SOYBEAN ISOLINES UNDERGOING WATER STRESS CONDITIONS,
Nebraska Univ.-Lincoln. Center for Agricultural Meteorology and Climatology.
A. F. Garay, and W. W. Wilhelm.
Agronomy Journal, Vol. 75, p 973-977, November-December, 1983. 2 Fig, 4 Tab, 15 Ref.

Descriptors: *Roots, *Soybeans, *Isolines, *Water stress, Root development, Moisture uptake, Root distribution, Moisture availability.

Environmental stress may have a differential influence on root development of soybean 'Glycine max (L.) Merr.' isolines which vary in pubescence density. Root length density and root dry matter distribution as a function of depth and distance from the row were determined for two isolines of 'Harosoy' soybean in association with an experiment designed to evaluate the influence of epidermal pubescence on root development, water use, and photosynthetic characteristics of the two isolines. The isolines, Harosoy normal (HN) and Harosoy dense (HD), differed in the density of trichomes on the epidermal surfaces of leaves, stems, and pods. Root samples were collected 47 (full bloom) and 78 (beginning seed) days after planting. Until the first sampling, soil water content was high at all depths, and roots were concentrated in the surface 0.15-m layer, especially under the row. Eighty percent of the roots were found within the upper 0.30 m. By 78 days after planting and after 30 days of drought, root length density was greatest at the 0.90 to 1.20-m layer, 80% of the roots were found within the 0 root 1.2-m layer; and uniform lateral distribution was observed. Harosoy dense pubescence isoline tended to have a greater root density, to explore deeper into the soil, and to extract more soil water during the drought than did the normal pubescence isoline. However, the rate of water extraction (per unit root length) was greater for the HN isoline. (Murphy-IVI)

MOISTURE STRESS AND N REDISTRIBUTION IN SOYBEAN,

Kentucky Agricultural Experiment Station, Lexington. Dept. of Agronomy.
D. B. Egli, L. Meckel, R. E. Phillips, D. Radcliffe, and J. E. Leggett.
Agronomy Journal, Vol. 75, p 1027-1031, November-December, 1983. 1 Fig, 4 Tab, 21 Ref.

Descriptors: *Moisture stress, *Nitrogen, *Distribution, *Soybean yield, Irrigation effects, Trickle irrigation, Nitrogen fixation.

The redistribution of N from vegetative plant parts to the developing seed of soybean 'Glycine max (L.) Merr.' may influence the duration of seed filling and yield. The objective of this study was to investigate the effect of moisture stress during various developmental stages on N redistribution. Soybean (cv. Williams) was grown in the field at Lexington, Ky., for 3 years (1979 to 1981) on a Maury silt loam (fine, mixed, mesic Typic Paleudalf) soil. Irrigated controls were compared with moisture stress treatments from planting to beginning seed fill (growth stage R5), during seed filling (growth stage R5 to R7) or throughout the growing season. Stress was applied by not irrigating until the soil water potential reached -300J/kg or by covering the soil with black plastic after emergence to allow severe stress to develop. Plant weight at growth stage R5 and yield were affected by the moisture stress treatments, however, moisture stress had only a limited effect on N concentration in the plant tissue. The proportion of seed N that came from redistribution varied among treatments and years from 33 to 102% with no consistent relationship between the level or timing of moisture stress and the contribution of redistributed N to seed N. The proportion of the N in the vegetative plant and pod walls that was redistributed was nearly constant across treatments and years. The contribution that redistributed N makes to the seed N at maturity is more closely related to the amount of N available for redistribution than it is to ability of plants to obtain N from the soil or via N2 fixation during seed filling. COMPARATIVE PHYSIOLOGY AND WATER RELATIONS OF TWO CORN HYBRIDS DURING WATER STRESS,
Du Pont de Nemours (E.I.) and Co., Wilmington, DE. Central Research and Development Dept.
R. C. Ackerson.
Crop Science, Vol. 23, No. 2, p 278-283, March-April, 1983. 8 Fig, 26 Ref.

Descriptors: *Corn, *Plant physiology, *Water stress, Plant water potential, Leaves, Drought, Water conveyance.

Water stress usually reduces crop growth and productivity. Although several important physiological processes can be dramatically altered by water stress, it is uncertain which processes are important with respect to adaptation, acclimation tolerance or resistance to drought. One hybrid (XL62AA) was a good drought tolerant commercial hybrid, while the other was an experimental hybrid (LH) derived from a cross of two Latente parents. The hybrids were compared to assess their relative responses to water stress. The LH hybrid exhibited higher rates of leaf photosynthesis than the XL62AA hybrid, but only a high leaf water potentials. Photosynthetic rates of both hybrids decreased as leaves aged. The LH hybrid maintained higher levels of soluble sugars and starch in the leaves as water potentials declined, perhaps owing to higher photosynthetic. The concentration of abscisic acid was also higher in the LH hybrid particularly when plants became water stressed. Comparisons of the internal water relations between the hybrids indicated that differences in the leaf turgor-leaf water potential relationship existed only during the time tassels were emerging. During this period, the LH hybrid maintained higher turgor pressures at all leaf water potentials compared with the XL62AA hybrid. When stress was imposed during the time of rapid leaf expansion and the mid-grain filling stages of development, the leaf turgor-leaf water potential relationships were similar in the two hybrids. The LH hybrid exhibited certain physiological characteristics that may allow greater drought tolerance or resistance when compared with a good drought tolerant commercial hybrid. As such, the LH hybrid may represent an important source of germplasm for developing more drought tolerant hybrids. (Murphy-IVI)

YIELD, WATER RELATIONS, GAS EXCHANGE, AND SURFACE REFLECTANCES OF NEAR-ISOGENIC WHEAT LINES DIFFERING IN GLAUCOUSNESS,
Agricultural Research Service, Logan, UT. Crops Research Lab.
D. A. Johnson, R. A. Richards, and N. C. Turner.
Crop Science, Vol. 23, No. 2, p 318-325, March-April, 1983. 4 Fig, 5 Tab, 21 Ref.

Descriptors: *Crop yield, *Plant water potential, *Reflectance, *Wheat, *Glaucous, Soil water potential, Water use efficiency, Epicuticular wax, Transpiration, Leaves, Drought resistance.

Near-isogenic lines that contrast in the presence or absence of glaucousness were developed in durum wheat (Triticum turgidum L. durum group) and common wheat (T. aestivum L.) and grown in plots in three field environments varying in soil water availability. The glaucous selections yielded significantly more grain and dry matter than non-glaucous selections in the two higher yielding environments but not in the very dry environment where average yield was 66 g/sq m. No differences within or between lines were found in soil water extraction patterns. Furthermore, leaf water potentials determined at predawn and midday exhibited no consistent differences between glaucous and non-glaucous selections. Lines selected for glaucousness varied in wax content of the different plant parts. Although differing in glaucousness, the glaucous selections did not necessarily exhibit greater amounts of epicuticular wax. Field gas exchange measurements for flag leaves and sheaths also indicated no beneficial or detrimental effects of glaucousness at saturating light and optimum temperature for photosynthesis. Surface reflectances in the 400 to 700 nm wavelengths were the same for the adaxial surface of the flag leaf, but were 8 to 15% higher in the glaucous than non-glaucous selections of one line for the ear, sheath, and abaxial flag leaf surface. Reflectances increased linearly with amount of epicuticular wax and were greater in the driest environment. The greater yield of the glaucous over the non-glaucous lines is discussed in relation to differences in reflectance and the possible influence of glaucousness on tissue temperature, leaf area duration, and other factors. GENOTYPIC VARIATION FOR GLYCINEBETAINE ACCUMULATION BY CULTIVATED AND WILD BARLEY IN RELATION TO WATER STRESS,
Shell Development Co., Modesto, CA.
J. A. R. Ladyman, K. M. Ditz, R. Grumet, and A. D. Hanson.
Crop Science, Vol. 23, No. 3, p 465-468, May-June, 1983. 1 Fig, 4 Tab, 19 Ref. Dept. of Energy contract DE-AC02-76-ERO1338.

Descriptors: *Glycinebetaine, *Accumulation, *Cultivation, *Barley, *Water stress, Drought resistance, Betaine.

The accumulation of betaine (glycinebetaine, N,N,N-trimethylgly-cine) in barley (Hordeum vulgare L.) during water stress may be of adaptive value. The objective of this research was to evaluate the variability for betaine level among genotypes of H. vulgare and H. spontaneum C. Koch in preparation for a physiological-genetic assessment of the adaptive value of betaine accummulation. Betaine was determined using either a pyrolysis/gas chromatographic method or a periodide spectrophotometric assay, specially modified for screening. In controlled environment tests, 339 genotypes were grown to the four-leaf stage under well-watered conditions and analyzed for shoot betaine level; 145 of these were also tested under water-stressed conditions. There were significant differences for betaine level among genotypes, both without and with water stress (approximate ranges of betaine levels: 10 to 40 micromol/g dry wt in well-watered conditions; 35 to 90 micromol/g dry wt under stress). The betaine levels of stressed plants were significantly correlated with those of unstressed plants of the same genotype. Thirteen H. vulgare cultivars which were high and low accumulators in controlled environments were grown in the field under simulated dryland conditions and betaine was analyzed in the upper leaves. At the ear emergence stage, significant variation for betaine level was observed among cultivars although there were no significant differences in their water status. Those cultivars that accumulated either high or low levels of betaine in controlled environments accumulated respectively high or low levels in the field, the correlation among cultivars in the two environments was highly significant (r = 0.71). These results indicate that genotypic variability for betaine level is expressed in both controlled environmental and in the field, and that this variabiity is unlikely to be due solely to variability for water status. Physiological-genetic studies of the adaptive role of betaine may thus be possible. (Author's abstract)

IRRIGATION OF SOYBEAN GENOTYPES DURING REPRODUCTIVE ONTOGENY. I AGRONOMIC RESPONSES,
Nebraska Univ.-Lincoln. Dept. of Agronomy.
L. L. Korte, J. H. Williams, J. E. Specht, and R. C. Sorensen.
Crop Science, Vol. 23, No. 3, p 521-527, May-June, 1983. 4 Fig, 1 Tab, 37 Ref. Nebr. Agric. Exp. Stn. projects 12-012 and 12-091.

Descriptors: *Irrigation, *Soybeans, Soil moisture, Water stress, Cultivars, Seed yield, Irrigation management, Irrigation effects.

Successful irrigation management for soybean 'Glycine max (L.) Merr.' requires a knowledge of the effect of irrigations applied during specific stages of reproductive ontogeny. Eight soybean cultivars, varying in stem growth habit and maturity, were subjected to a factorial set of eight irrigation treatments involving either no irrigation or one irrigation applied at three reproductive stages: R1 to R2 flowering (F), R3 to R5 pod elongation (P), or R5 to R6 seed enlargement (S). The experiment was conducted for 3 years on a Sharpsburg silty clay loam (Typic Argiudoll). An F irrigation had little effect on ultimate seed yield (+ 20 kg/ha) and for some cultivars actually depressed yield below that of the nonirrigated check. A P irrigation consistently increased seed yield (+379 kg/ha), irrespective of cultivar or year. An S irrigation also enchanced seed yield (+384 kg/ha), but the degree of enhancement was inconsistent across years, being influenced by the amount of natural rainfall occurring during the seed enlargement stage. Although a dual F-P irrigation treatment enhanced seed yield above that for both the nonirrigated check and single F irrigation treatment, the seed yield increase was significantly smaller (+16 kg/ha) than that achieved with a single P irrigation treatment. Soybean maturity was delayed 2 to 3 days with irrigation but the delay was greater when irrigation was applied late in reproductive ontogeny. This senescence delay lengthened the seed-fill period and was responsible in part for the seed yield enhancement effected by irrigation. Increases in soybean plant height and lodging were greatest with an F irrigation, intermediate with a P irrigation, and minimal with an S irrigation. Although irrigation effects on seed quality were variable depending on the cultivar, there was an overall tendency for a P irrigation to improve and an F irrigation to worsen seed quality. An F irrigation had no effect on seed quality. Of the eight cultivars evaluated, the determinate 'Elf' was the most yield responsive to irrigation and was relatively resistant to changes induced by irrigation in plant height, lodging, and seed quality. Based on these data, optimal yield enhancement in irrigated soybean culture can be achieved with the use of short stature or lodging-resistant cultivars irrigated during pod elongation (R3 to R4) and seed enlargement (R5 to R6).

IRRIGATION OF SOYBEAN GENOTYPES DURING REPRODUCTIVE ONTOGENY II. YIELD COMPONENT RESPONSES,
Nebraska Univ.-Lincoln. Dept. of Agronomy.
L. L. Korte, J. E. Specht, J. H. Williams, and R. C. Sorensen.
Crop Science, Vol. 23, No. 3, p 528-533, May-June, 1983. 4 Fig, 1 Tab, 13 Ref. Nebr. Agric. Esp. Stn. projects 12-091 and 12-012.

Descriptors: *Irrigation, *Soybean yield, Phenology, Irrigation effects, Water stress, Soil moisture, Growth stage.

The magnitude of a seed yield increase that occurs when soybeans 'Glycine max. (L.) Merr.' are irrigated depends upon the phenologic timing of the irrigation in relation to the temporal sequence with which the components of seed yield are established and fixed. Eight soybean cultivars, varying in stem growth habit and maturity, were irrigated according to a factorial treatment design in which either no irrigation or one irrigation was applied at three reproductive stages: R1 to R2 flowering (F), R3 to R4 pod elongation (P), or R5 to R6 seed enlargement (S). An F irrigation increased the numbers of pods/plant (+2.8) and seeds/plant (+5.8), but an offsetting decrease occurred in 100-seed weight (-0.9 g), resulting in little change in seed yield. A P irrigation had no effect on 100-seed weight, but increased the numbers of pods/plant (+3.4) and seeds/plant (+7.9) resulting in a large increase in seed yield. An S irrigation resulted in only slight increases in the numbers of pods/plant (+1.0) and seeds/plant (+3.3), but greatly increased 100-seed weight (+1.4 g), again leading to a large seed yield increase. These observations suggested that irrigation early in reproudctive ontogeny greatly reduced flower and pod abortion, whereas irrigation later in ontogeny reduced ovule abortion within developing pods. The cultivar 'Harcor' possessed unusually high numbers of one-and two-seed pods, while 'Elf' had substantially fewer numbers of three-seed pods, and 'Woodworth' possessed larger numbers of four-seed pods. Irrigation timing differentially influenced the frequencies of the various pod classes relative to their contribution to the increase in total pods/plant, primarily because of effects on ovule abortion within developing pods. The effects of irrigation timing on number of seeds/plant and 100-seed weight were thus consistent with the effects on seed yield reported earlier. (Author's abstract)

ALFALFA RESPONSE TO SOIL WATER DEFICITS. I. GROWTH, FORAGE QUALITY, YIELD, WATER USE, AND WATER-USE EFFICIENCY,
Minnesota Univ., St. Paul. Dept. of Agronomy and Plant Genetics.
P. R. Carter, and C. C. Sheaffer.
Crop Science, Vol. 23, No. 4, p 669-675, July-August, 1983. 9 Fig, 3 Tab, 33 Ref. OWRT, USDI grant 14-34-0001-1236-B158 MINN.

Descriptors: *Alfalfa, *Soil water, *Plant growth, *Crop yield, *Water use, *Water use efficiency, Soil-water-plant relationships, Drought resistance, Irrigation effects, Evapotranspiration, Soil moisture deficiency, Leaves.

Although many researchers have reported yield increases due to alfalfa irrigation when soil water has been limited, little information is available on alfalfa plant and soil water relationships which might be used to improve water management strategies. Our objective was to determine effects of plant water deficits on alfalfa seasonal growth patterns, forage quality, forage yield, water use, and water-use efficiency. During 1981, established alfalfa grown on a sandy soil was subjected to four water supply levels designated: high irrigation (H), medium high irrigation (MH), medium low irrigation (ML), and unirrigated, rainfall only (U). Soil water depletions occurred for all treatments to at least 1.9 m. Alfalfa midday plant water potentials (psi mp) in H and MH treatments ranged from -0.7 to -1.3 MPa throughout the season. For alfalfa subjected to ML and U treatments, psi mp reached -2.7 and -4.0 MPa, respectively. Dry weight (DW) accumulations for alfalfa in H and MH treatments increased with successive harvests during the summer while harvest DW for alfalfa in ML and U treatments declined. Relative growth rate (RGR) declined sharply as psi mp decreased. At moderate plant water stress (psi mp of -1.5 to -2.0 MPa), little growth occurred and under severe water stress, (psi mp of -1.5 to -2.0 MPa), little growth occurred and under severe water stress, (psi mp < -2.5 MPa), RGR were negative due to leaf loss. Reduced soil water availability resulted in increased leaf stem weight ratios and in vitro dry matter disapperance (IVDMD), but only under severe and long-term plant water stress. Crude protein (CP) concentration was unaffected by plant water status. It appeared that irrigation water could be used efficiently on coarse-textured soils by moderate water application to alfalfa at 50% depletion of extractable soil water, an apparent threshold for maintenance of favorable plant water status. A close associations between forage yield of individual harvests and cumulative psi mp indicates potential for initiation of irrigations when plant measurements indicate soil water depletions to a threshold level. ALFALFA RESPONSE TO SOIL WATER DEFICITS. III. NODULATION AND N2 FIXATION,
Minnesota Univ., St. Paul. Dept. of Agronomy and Plant Genetics.
P. R. Carter, and C. C. Sheaffer.
Crop Science, Vol. 23, No. 5, p 985-990, September-October, 1983. 7 Fig, 2 Tab, 19 Ref.

Descriptors: *Alfalfa, *Soil moisture deficit, *Nitrogen fixation, Soil-water-plant relationships, Irrigation effects, Plant water potential, Soil water potential.

Harvesting of forage legumes removes the photosynthate source necessary of remaintaining N2 fixation and nodule development. Water stress also depresses legume N2 fixation. In a field study on Typic Hapludoll (silt loam) soil, nitrogenase specific activity (NSA), nodule numbers, and shoot and root growth of irrigated and nonirrigated alfalfa were measured during a harvest/regrowth cycle. In a glasshouse study with Udorthentic Haploboroll (loamy sand) soil, NSA, nodulation, shoot and root growth, and root total nonstructural carbohydrate (TNC) concentration of nonharvested and harvested alfalfa were monitored during two successive harvest/regrowth cycles. Both harvest treatments were subjected to a range of soil and plant water deficits. Forage harvest decreased NSA and root TNC concentration for well-watered alfalfa, but changes in NSA for water-stressed plants were more associated with fluctuations in plant water (psi p) and soil matric (psi m) potentials than to removal of herbage or level of root carbohydrates. Nitrogenase specific activity declined linearly as psi p decreased to -3.0 PMa, at which point activity approached zero. Alfalfa nodules subjected to severe water stress were able to resume activity when soil moisture levels were restored. Nodulation was inhibited by well-watered conditions (mean psi m of -0.015 MPa) in the silt loam and by soil water deficits (mean psi m of -0.07 to -0.51 MPa) in the loamy sand. (Murphy-IVI)

ROLE OF PANICLE EXSERTION IN WATER STRESS INDUCED STERILITY,
International Rice Research Inst., Los Banos, Laguna (Philippines). Dept. of Agronomy.
J. C. O'Toole, and O. S. Namuco.
Crop Science, Vol. 23, No. 6 , p 1093-1097, November-December, 1983. 3 Fig, 1 Tab, 22 Ref.

Descriptors: *Panicle, *Exsertion, *Water stress, *Sterility, Rice, Plant water Potential, Sprinkler irrigation, Leaves, Rproductivity, Evapotranspiration.

Although the sensitivity of crop species to water stress during reproductive growth stages is well documented, the causes of sterility are not understood. Rice cultivar IR36 was grown on a deep silty loam soil under full sprinkler irrigation for 77 days. A line source sprinkler system was then utilized during panicle exsertion and flowering to impose six continuously decreasing irrigation treatments. After the 15-day treatment period, full sprinkler irrigation was resumed until maturity. Soil moisture extraction and plant water potential were monitored as soil and plant water stress progressed. Panicle exsertion rate was measured on tagged panicles which were later used to assess percent final panicle exsertion and percent sterility. The six irrigation treatments varied in grain yield from 5.0 t/ha to about 1 t/ha with corresponding increases in spikelet sterility of 16.6 and 74.2%. Panicle exsertion rate decreased linearly with decreasing mean daily leaf water potential. The degree of final panicle exsertion from the flagleaf sheath and percent spikelet sterility both decreased linearly with panicle exsertion rate. All spikelets left unexserted from the flagleaf sheath were sterile. Panicle exsertion rate was slightly confounded by tiller age in that late tillers in the well irrigated treatment had a slower exsertion rate and higher percent sterility than earlier tillers. The early tillers which exserted at rates of 4.5 to 5.5 cm/day under well watered conditions decreased to about 3.0 cm/day in the stressed plot and accounted fo 25 to 30% spikelet sterility in the severely stressed treatment. SIGNIFICANCE OF ACCELERATED LEAF SENESCENCE AT LOW WATER POTENTIALS FOR WATER LOSS AND GRAIN YIELD IN MAIZE,
Navarra Univ., Pamplona (Spain). Dept. Fisiologia Vegetal.
P. M. Aparicio-Tejo, and J. S. Boyer.
Crop Science, Vol. 23, No. 6, p 1198-1202, November-December, 1983. 7 Fig, 19 Ref. NSF grant PCM 79-09790.

Descriptors: *Leaves, *Water potentials, *Senescence, *Water loss, *Maize yield, Transpiration, Stomatal transpiration, Dry matter, Water conservation.

Productivity is lost when plants are subjected to dry soil conditions and this loss is often accompanied by the senescence of leaf tissue. The role of leaf senescence in water conservation and grain production was therefore evaluated in maize (Zea mays L.) subjected to low water potentials for most of the grain filling period. The plants were grown in soil in controlled environment chambers and water was withheld from the soil after pollination had occurred. Low leaf water potentials were maintained for 30 days (until the grain matured) by daily addition of small amounts of water to the soil. The low water potentials (-1.8 to -2.0 MPa) inhibited dry matter accumulation and transpiration by the plants. However, in addition to the initial inhibition of transpiration by stomatal closure, there was a further inhibition (about 11% of the control rate) associated with accelerated senescence of the leaves. Excision of senesced leaf tissue showed that, despite this inhibition of water loss attributable to senescence, the dead tissue itself continued to lose a small amount of water while attached to the plants. Although the low water potentials were of long enough duration to allow significant acclimation of the plants, the senescing tissue contributed only a small amount of dry matter to the grain by mobilizing leaf constituents. Since the amount of water conserved by the senescing tissue was also small, it is likely that accelerated leaf senescence contributes little to grain production at low water potentials and has the disadvantage that it sacrifices potential photosynthetic surface. Therefore, selection against accelerated senescence of leaves at low water potentials may be desirable for crops. (Author's abstract)

CROP-CLIMATE MODELING USING SPATIAL PATTERNS OF YIELD AND CLIMATE. PART 1: BACKGROUND AND AN EXAMPLE FROM AUSTRALIA,
University of East Anglia, Norwich (England). Climatic Research Unit.
T. M. L. Wigley, and T. Qipu.
Journal of Climate and Applied Meteorology, Vol. 22, No. 11, p 1831-1841, November, 1983. 5 Fig, 3 Tab, 22 Ref.

Descriptors: *Crop yield, *Climates, *Australia, Wheat, Model studies, Spatial distribution, Statistical models, Multivariate regression analysis.

Crop yield is certainly dependent on the weather conditions prevailing during, and sometimes prior to the growing season, expressing this dependence in terms of a reliable quantitative relationship, a crop-climate model, is a difficult task. The direct linking of spatial patterns of crop yield and spatial patterns of climate is a new statistical crop-climate analysis technique. Yield and climate data from networks of crop reporting districts and meteorological stations are decomposed into orthogonal components using principal components analysis. A function of the climate components is then used to express each yield component using multiple regression. The combining of these regression equations gives an equation which relates interannual variations in the spatial patterns of yield to interannual variations in the spatial patterns of selected climate variables. Wheat yield data from 59 crop reporting districts in southwestern Australia from the period 1929-1975 are used to illustrate the method. The climate contribution is shown to be highly significant, with winter precipitation being the most important variable. A single equation relating yield and climate patterns correctly reproduces the differing results obtained for separate parts of the study area by earlier workers. The influence of winter and autumn precipitation is nonlinear and the study divides therefore into three zones: a high rainfall area where rainfall is generally more than optimum so that lower rainfall gives higher yields; a low rainfall area where rainfall is less than optimum so that positive rainfall anomalies are associated with higher yields; and an intermediate zone where average rainfall is close to optimum so that anomalies in either direction suppress yields. No evidence was found for any significant change in the sensitivity of wheat yields to climate in spite of a complete change in the variety of wheat cultivated. (Baker-IVI)

WATER USE BY ALFALFA, MAIZE, AND BARLEY AS INFLUENCED BY AVAILABLE SOIL WATER,
New Mexico State Univ., Las Cruces. Dept. of Crop and Soil Sciences.
A. S. Abdul-Jabbar, T. W. Sammis, D. G. Lugg, C. E. Kallsen, and D. Smeal.
Agricultural Water Management, Vol. 6,. No. 4, p 351-363, 1983. 5 Fig, 2 Tab, 29 Ref. OWRT projects A-063 N.Mex., B-069 N.Mex., and C-90229.

Descriptors: *Alfalfa, *Corn, *Barley, *Water use, *Soil water, Evapotranspiration, Available water, Sprinkler irrigation, Soil types.

The availability of soil water is one of the most important determinants of crop production. Field studies were conducted to examine the relationships between relative evapotranspiration (E/E sub max) and available water (W) for alfalfa, maize, and barley. Line source sprinkler irrigation systems were used to provide the variations in soil moisture. Actual evapotranspiration (E) was determined using the water balance method. Maximum evapotranspiration (E sub max) was the highest E observed among all irrigation levels. Potential evapotranspiration (E sub 0) was estimated using Penman's equation to characterize the evaporative demand. The results show that the relationships between E/E sub max and W were different for the three crops. For alfalfa, the relationship was dependent on the physical properties of the soil and on E sub 0. In a clay loam soil, the declines in E from E sub max commenced at a higher value of W than in a sandy loam soil. Furthermore, the rate of decline in E from E sub max was dependent on E sub 0 and was greater as E sub 0 increased. In the sandy loam soil, the relationship between E/E sub max and W was not dependent on E sub 0. For maize and barley in clay loam soils, E/E sub max as a function of W was linear, and was not dependent on E sub o. This study was compared to results reported in the literature, and it was hypothesized that differences were related mainly to the way variation in soil moisture was introduced over the measurement period. WHEAT ROOT GROWTH, GRAIN YIELD AND WATER UPTAKE AS INFLUENCED BY SOIL WATER REGIME AND DEPTH OF NITROGEN PLACEMENT IN A LOAMY SAND SOIL,
Indian Grassland and Fodder Research Inst., Jhansi.
B. R. Sharma, and T. N. Chaudhary.
Agricultural Water Management, Vol. 6, No. 4, p 365-373, 1983. 3 Fig, 3 Tab, 16 Ref.

Descriptors: *Crop yield, *Wheat, *Soil water, *Growth, *Nitrogen, Irrigation effects, Water table, Water uptake, Roots, Water use.

Root growth, grain yield and water uptake by wheat in relation to soil water regime and depth of nitrogen (N) placement were studied in metallic cylinders filled with loamy sand soil. Root-length and -weight densities were greater under irrigated than under un-irrigated conditions and they increased with deep placement as compared to surface mixing of fertilizer N. The differences were relatively larger in the deeper than in the upper soil layers and increased during later stages of plant growth. Under non-irrigated conditions, constant water table at 100 cm depth produced maximum root growth in the top 30 cm soil. Water uptake rate increased with increase in root density depending on root age and soil water status. Dry matter accumulation at different stages of plant growth and grain yield varied significantly with moisture regime and depth of N placement. Deep placement of fertilizer N under shallow water table and non-irrigated conditions caused greater root growth, better water utilization and a higher production. (Author's abstract)

2J. Erosion and Sedimentation

THE BEHAVIOUR OF SILT-LADEN CURRENT,
Ecole Polytechnique Federale de Lausanne (Switzerland). Lab. d'Hydraulique.
W. H. Graf.
International Water Power and Dam Construction, Vol. 35, No. 9, p 33-37, September, 1983. 9 Fig, 11 Ref.

Descriptors: *Sedimentation, *Reservoirs, Density currents, Gravity currents, Turbidity currents, Stratification, Stagnant water, Turbidity, Sediment transport, Silt.

Density currents are considered as they are encountered when sediment-laden river flow enters an almost stagnant water body, such as a reservoir or lake. Density currents have features in common with open-channel flows, but differ essentially because the buoyancy of the surrounding fluid reduces the gravity force by a normalized density difference. Gravity will inhibit the deep layer from mixing with the density current along the slope. Density currents may deposit sediments from the current onto the bed, erode sediments from the bed and carry them with the current, or may be steady state currents where an equilibrium between bed erosion and deposition exists. Proper knowledge of density current implications will aid in the determination of the loss of storage capacity as a result of settling out of suspended matter; the proper installation and operation of the opening gates which might well conserve a part of the storage capacity normally destroyed by deposition; the prediction and management of the lake's water quality (turbidity); the proper handling and use of density currents to empty out already accumulated sediment; and the avoidance of wear on hydraul machinery and duct linings. Doklady Biological Sciences, Vol. 267, No. 1-6, 554-558, November-December, 1982. 4 Fig, 4 Re Translated from Doklady Akademii Nauk SSS Vol. 267, No. 4, p 1012-1016, December, 198

Descriptors: *Model studies, *Ecosystems, *Si Mathematical studies, Biomass, Oxidation, Su strates.

A generalized model of the process of aerob biological purification is based on the assertion th the composition of microorganisms in reactors pe forming the purification process depends upon t range of the processed pollutants. The latter determined not only by the type of waste wate but also depends on the conditions of reactor ope ation. A system is examined with active silt, repr senting an ideal reactor-elutor in which polluta oxidation and biomass accumulation occur, and settling tank in which the biomass is compact and then returned to the reactor-aeration tank. T model demonstrated that to each magnitude of s stress there corresponds a specific species compo tion of the active-silt microflora. The fraction species oxidizing those difficult to oxidize polluta components increases with a decline in silt stre The purification effect increases when a multista purification is used, where the microorganism sp cies composition is formed at each stage. he universal soil loss equations is applied to a udy site on the Caribou-Poker Creeks Research Vatershed (Alaska) in order to assess the suitabil- y of the equation for predicting sheet-rill erosion Alaska's interior. When a permafrost-free su- rctic setting is stripped of all vegetation from the il surface, an increase in rainfall erosion is 16 nes that produced from an undisturbed forest. he rate difference is from 0.008 ton per acre per ear to 0.13 ton per acre per year. Removing the ees from a forested area, with only minor disturb- ace of ground cover, did not increase erosion. A ehicle trail on permafrost terrain had a very low rosion rate of 0.03 ton per acre per year. Compar- on of measured erosion with erosion predicted by he universal soil loss equation indicated that the quation overestimated annual rainfall erosion by n average of 21% and overestimated individual orm erosion by an average of 174%. The stand- rd deviation of the mathematical model was 28%. (Murphy-IVI)

OIL AND NUTRIENT RUNOFF LOSSES VITH IN-ROW, CHISEL-PLANTED SOY- EANS,
gricultural Research Service, Watkinsville, GA.
. W. Langdale, H. F. Perkins, A. P. Barnett, J. C. eardon, and R. L. Wilson, Jr.
ournal of Soil and Water Conservation, p 297-301, lay-June, 1983. 1 Fig, 5 Tab, 20 Ref.

escriptors: *Soil erosion, *Nutrients, *Runoff, Soybeans, *Conservation tillage, Agricultural unoff, Crop residues, Nutrient losses, Mulches, ye.

Coulter, in-row chiseling 20 centimeters deep in ye stubble effectively controlled runoff (less than r equal to 13%) on rainulator plots (10.7- and 1.4-meter slope lengths) with a 7% slope until vater content in the topsoil approached 14.2% about 0.1-bar suction). In-row chiseling and soil over collectively reduced soil losses during rainu- ator runs to less than 0.5 metric ton per hectare on oth slope lengths. Increased slope length led to ncreased runoff, event with low soil water content luring soybean canopy development. Removing rop residue and destroying the chisel slot with omplete tillage caused soil losses exceeding 40 netric tons per hectare. Runoff-weighted nutrient osses related positively to soil losses. Increased lope length consistently increased nutrient losses luring all tillage-soil cover sequences. Most nutri- nt loss variation was accounted for by treating oil loss as an independent variable during the rye nulch cover period. Phosphorus losses were corre- ated better to soil losses among tillage-soil cover equences than to the cations. Coulter, in-row, chisel-planted soybeans through rye residues fol- owing winter-spring cattle grazing of rye effec- ively controlled runoff as well as soil loss and ome nutrient losses. (Murphy-IVI)

SOIL EROSION FROM FIVE SOYBEAN TILL- AGE SYSTEMS,
Tennessee Univ., Knoxville. Dept. of Agricultural Engineering.
C. H. Shelton, F. D. Tompkins, and D. D. Tyler.
Journal of Soil and Water Conservation, p 425-428, September-October, 1983. 8 Tab, 6 Ref.

Descriptors: *Soil erosion, *Soybeans, *Tillage, Runoff, Rainfall, Simulation, Soil types, Loess, Agricultural runoff.

Runoff from natural and simulated rainfall on 0.25 acre plots caused significant soil losses from soybean plots and five different tillage systems on a highly erodable soil in West Tennessee. Soil losses generally were greatest for the conventional-till, single-crop soybean system, followed in order by drilled soybeans; conventional-till, double-cropped soybeans; no-till, double-cropped soybeans; and no-till, single-cropped soybeans. Weed control was attained without the use of herbicides. Because each of the five systems has advantages and disadvantages, a program of rotating alternate strips of a no-till system with a conventional-till, double cropped system would have merit. To control erosion and accompanying loss of nutrients, however, each system should provide soil cover when high-energy rainfall is most likely to occur. (Murphy-IVI)

PROBABILITY SAMPLING TECHNIQUES FOR ESTIMATING SOIL EROSION,
Utrecht Rijkuniversitet (Netherlands). Dept. of Physical Geography.
J. M. Roels, and P. J. Jonker.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1224-1228, November/December, 1983. 5 Fig, 4 Tab, 11 Ref.

Descriptors: *Soil erosion, *Sampling, *Probability, Rill erosion, Interrill erosion, Soil loss, Ardeche drainage basin, France.

Soil erosion in a particular area can be estimated from measurements at sites which are thought to be representative of the entire area. Modified Gerlach troughs were used to measure both rill and interrill erosion in the rangelands of the Ardeche drainage basin in France. Random, systematic, stratified random, and cluster sampling methods were tested for various numbers of plots and plot widths in order to find the method that gives the most accurate estimate of soil loss. If both the rill and interrill subpopulations are sampled, random sampling and stratified random sampling give almost identical standard errors. Cluster sampling yields large errors and is therefore less effective. Systematic sampling, however, allows one to choose more accurate samples of an economical size, but its efficacy depends largely on the number of rills in the study area. The smallest standard errors are obtained by measuring the total rill erosion and by sampling only the interrill subpopulation. When this procedure is applied, the four sampling methods turn out to be equally accurate. The size and number of erosion plots to be used in soil loss measurements in a study area depend on the purpose of the experiments. Only for a rapid reconnaissance of the extent of soil erosion are data with low or unknown accuracy acceptable. Probability sampling techniques allow the accuracy of the plot data to be determined. RAINFALL EROSION INDICES FOR CANADA EAST OF THE ROCKY MOUNTAINS,
Department of Agriculture, Guelph (Ontario).
G. J. Wall, W. T. Dickinson, and J. Greuel.
Canadian Journal of Soil Science, Vol. 63, No. 2, p 271-280, May, 1983. 4 Fig, 3 Tab, 13 Ref.

Descriptors: *Rainfall index, *Erosion, Canada, Rocky Mountains, Mountains, Soil loss, Mathematical equations.

Relatively simple techniques for estimating average annual rainfall erosion indices and seasonal distribution patterns of rainfall erosion yield values comparable to those determined by more tedious methods in the United States. These techniques have proven to be extremely useful for the development of a first approximation of rainfall erosion indices for Canadian locations east of the Rocky Mountains. There is a significant range of rainfall erosion index values across the country. There are definite regional patterns for both the annual index and the monthly distributions. The data base of climatic stations used in this study has proven to be large enough to yield realistic broad patterns for a large portion of Canada. (Baker-IVI)

ESTIMATES OF SOIL EROSION AND DEPO- SITION FOR SOME SASKATCHEWAN SOILS,
Saskatchewan Univ., Saskatoon. Dept. of Soil Science.
E. De Jong, C. B. M. Begg, and R. G. Kachanoski.
Canadian Journal of Soil Science, Vol. 63, No. 3, p 607-617, August, 1983. 2 Fig, 6 Tab, 22 Ref.

Descriptors: *Erosion, *Estimating, Saskatchewan, Soil loss, Water erosion, Wind erosion, Universal soil loss equation, Mathematical equations.

Traditional cultivation practices involving large tracts of land in summerfallow have encouraged wind and water erosion on the Prairies and have reduced soil fertility. Actual measurement of soil loss by erosion can be obtained from field plots maintained over many years. Cs-137 from the atmospheric testing of nuclear devices in the 1950s and 1960s was used to estimate soil erosion in eight small basins in hummocky topography. Three basins had not been cultivated since 1950 and in these Cs-137 showed little or no separation according to landscape position. In the cultivated basins Cs-137 varied significantly with slope position and could be used to identify areas of soil loss and deposition. The Cs-137 distribution in the cultivated basins indicates the simultaneous occurrence of erosion on the upper slope and deposition on the lower slope areas. Therefore the universal soil loss equation (USLE) is difficult to apply on this topography. The Cs-137 data could be used to estimate rates of soil loss or deposition at specific slope positions. The results of the Cs-137 balances did correctly separate basins in which wind erosion was known to be important, from basins where water erosion was probably the dominant process of soil movement. SOIL EROSION AND PRODUCTIVITY, A RA- TIONAL LOOK AT A COMPLEX SITUATION,
Minnesota Univ., Minneapolis. Dept. of Soil Science.
W. E. Larson, F. J. Pierce, and R. H. Dowdy.
Crops and Soil Magazine, Vol. 35, No. 9, p 19-20, August-September, 1983. 2 Fig.

Descriptors: *Soil erosion, *Crop yield, Acidity, Universal Soil Loss Equation, Corn Belt, United States, Erosion, Topsoil, Subsoil.

Various factors influence the productivity of a crop. Among these are the nature of the soil, the weather, the plant variety, such external sources as lime and fertilizer, and the management of all of these resources. The way a soil erodes and where it goes can both affect soil productivity. If the soil in leaving takes seedling plants with it, there will be an obvious decrease in crop production that year. If it leaves large gullies behind that cannot be farmed in the future, then the future yield is also affected. Soil eroding from a hillside and being deposited on a low spot on a field can either be detrimental or beneficial to productivity, depending on the landscape. Loss in productivity is thought to be greatest on slopes exceeding 6% and when subsoil properties are unfavorable for crop growth. About 29% of the cropland in the United

States is on slopes steeper than 6%. On generally fertile and deep soils of the Corn Belt, potential productivity will probably decline less than 10% in the next 50 years. (Baker-IVI)

A DYNAMIC MODEL OF BASIN SEDIMENT YIELD,
Institute of Hydrology, Wallingford (England).
R. J. Moore.
Water Resources Research, Vol. 20, No. 1, p 89-103, January, 1984. 34 Ref.

Descriptors: *Sediment yield, *Sediment transport, *River basins, *Mathematical models, Suspended sediments, Storm runoff, Floods.

A model of basin sediment yield was developed on the basis of continuous time functions which are twice-differentiated in the parameter space, thereby avoiding the function minimization problems encountered when calibrating models that employ threshold elements. The model predicts the hour-to-hour variation in basin suspended sediment yield, incorporating the phenomenon that yields are influenced by the availability of sediment, as well as the capacity of flow to transport sediment. This is achieved through the definition of three model functions: an availability function; a removal function; and a translation function. The inverse Gaussian probability density function is introduced as a suitable translation function because of its shape and its physical interpretation in terms of Saint Venant equations of open channel flow, the equations of groundwater flow, and the general convection-diffusion equation. A censored objective function is employed to facilitate efficient model calibration in circumstances where significant sediment yields are produced by infrequently occurring flood events, but the changing availability of sediment between storm events demands that the model be run continuously over time. Adoption of a modeling strategy based on the use of smooth but physically plausible functions was an important concern and motivation in developing the new model. The performance of basin sediment yield models must be severely limited on account of the complexity of the sediment yield process at the basin scale and the paucity of data usually available. This lack of definition at the basin scale provides a persuasive argument in favor of simple models which represents the dominant modes of behavior of the system. (Moore-IVI)

N. A. Zaghloul.
Advances in Water Resources, Vol. 6, No. 2, p 112-120, June, 1983. 18 Fig, 14 Ref.

Descriptors: *Alluvial channels, *Bed load, Sediment load, Channels, Sedimentation, Slopes, Mathematical equations, Kalinske's equation.

Because of the complexity and random nature of the problem of deposition and scour, the approaches to the study of these problems are empirical, or semi-empirical at best. Among the popular bed load formulae, Kalinske's equation gave the best correlation with the experimentally determined sediment discharge. The values of the energy slope, calculated by the resistance equations, are in reasonable conformity with the experimental values. A relatively better agreement was found for the starvation case than for sedimentation. The procedure which combines the bed load formulae and resistance equation produced reliable results for the conditions tested, and therefore, is recommended for practical application under the same conditions. Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 1896-1904, November, 1983. 3 Fig, 4 Tab, 46 Ref. EPA grant CR 809484.

Descriptors: *Acidification, *Hydrology, *Wisconsin, *Lakes, Surface runoff, Groundwater, Precipitation, Acidity, Chemistry of precipitation, Cluster analysis, Alkalinity, Inlets, Outlets.

Two hundred and seventy-five lakes were sampled in the summer of 1979 to assess the factors controlling susceptibility of northcentral Wisconsin lakes to acidification. In addition to direct evaluation of means and ranges of the physical and chemical characteristics, a cluster analysis was carried out using alkalinity, color, and chlorophyll a data. Three well-defined clusters emerged that appeared to be controlled by hydrology; A - dominated by surface runoff; B - dominated by groundwater; C - dominated by precipitation. Lake water quality and susceptibility are influenced by morphometric, hydrologic and terrigenous factors in 18 watersheds analyzed. Hydrologic factors were most important in differentiating the low alkalinity and high alkalinity lakes. The potentially sensitive low alkalinity lakes in northcentral Wisconsin lack surface inlets or outlets and their chemistry is closely associated with precipitation chemistry. (Murphy-IVI)

Descriptors: *Geochemistry, *Iron, *Manganese, *Sediments, *Bolstadfjord, *Norway, Interstitial water, Coastal waters, Physiochemical properties, Eddies, Fate of pollutants.

The near-surface circulation of Bolstadfjord is runoff dominated, while the deep waters are greatly restricted by the presence of shallow sills. The distribution of suspended particulate matter is closely allied to the general circulation, with the highest concentrations in the freshwater surface outflow. Elevated concentrations of dissolved and suspended particulate Fe and Mn are associated with restricted deep waters as a result of redox reactions and with river discharge. The basin sediments are anoxic throughout but because of the greatly restricted circulation, remobilized Fe and Mn appear to remain predominantly trapped within the fjord. Differentiation of Fe and Mn occurs to the extent that Fe sulfide precipitation is ubiquitous in the sediments whereas the entrapment of Mn, probably through Mn carbonate precipitation, is found only in the sediments of the more seaward basin (maximum Mn content of 1.5% by weight). The main controlling factors are probably a gradual build-up of Mn in the system and an increasing vertical eddy diffusion coefficient with depth. (Murphy-IVI)

Descriptors: *Ecosystems, *Copper, *Phosphorus, *Chemical binding, Iron hydroxide, Hypolimnion, Boundary conditions, Sediments, Organic matter, Nutrients, Bioavailability.

A system-analytical investigation of ecosystems elucidates those physical-chemical and biochemical processes which are relevant for the whole system. The system's balance of element and compound fluxes reflects the capacity of the 'biological program' to retain different chemical species for a longer or shorter time. This capacity is illustrated with copper(II) aqua ions and orthophosphate ions in an aquatic system. For phosphorus, a limiting nutrient in a lake, the biological subsystem 'sediment boundary layer' plays a crucial role. Within

this boundary layer an iron(III) hydroxide barrier reduces the phosphorus reflux into the hypolimnion. In the case of copper, an essential element having a toxic concentration in a purely inorganic form, natural dissolved organic matter reduces its bioavailability due to the formation of organic copper complexes. These dissolved forms of copper are exported more quickly. For both nutrients there is still a lack of data on the kinetics and the chemical nature of the chemical binding in the first (Cu) and the second sphere of coordination (P) with respect to the boundary conditions found in aquatic ecosystems. CARBONATE MINERALOGY OF LAKE SEDIMENTS AND SURROUNDING SOILS I. BLACKSTRAP LAKE,
Saskatchewan Univ., Saskatoon. Dept. of Soil Science.
K. Ghebre-Egziabhier, and R. J. St. Arnaud.
Canadian Journal of Soil Science, Vol. 63, No. 2, p 245-257, May, 1983. 5 Fig, 4 Tab, 28 Ref. NSERC Grant No. A1446.

Descriptors: *Lake sediments, *Mineralogy, Lakes, Blackstrap Lake, Saskatchewan, Canada, Carbonates, Minerals, Magnesium, Calcite, Dolomite, Erosion, Calcium, Chemical composition.

Carbonate minerals constitute an important fraction of many lake sediments. No detailed studies have yet been undertaken to establish the relationship between the carbonate mineralogy of lake sediments and that of surrounding soils and deposits. The similarity in carbonate mineralogy of the silt and clay fractions of the Blackstrap sediments to those of the surrounding soils suggests that erosional processes have contributed to the present composition of the lake sediment. In particular, the persistence of dolomite in the silt fractions of the lake sediment is a good indication that part of the calcite together with the dolomite are derived from the surrounding soils. However, the higher carbonate contents of the sediment fractions also indicate that the precipitation of carbonates from the lake waters has been and is likely to still occur. Mollusk shells also contribute to this increase. The presence of Mg-bearing calcite in the lake sediment is attributed to the pecipitation of calcite over a period during which the Mg(2+) ion concentration in the lake was increasing in relation to the Ca(2+) ion concentration. It appears that the Mg:Ca ratio of the waters has a similar effect on the nature of precipitated carbonates as that evident in marine deposits and soils. The unusual presence of Mg-bearing calcite in the sand fraction is attributed to the cementation of finer particles into sand-sized aggregates. (Baker-IVI)

A COMPARATIVE STUDY OF THE IONIC COMPOSITION OF RAINWATER AND ATMOSPHERIC AEROSOLS: IMPLICATIONS FOR THE MECHANISM OF ACIDIFICATION OF RAINWATER,
Lancaster Univ., Bailrigg (England). Dept. of Environmental Sciences.
R. M. Harrison, and C. A. Pio.
Atmospheric Environment, Vol. 17, No. 12, p 2539-2543, 1983. 1 Fig, 2 Tab, 27 Ref.

Descriptors: *Rainfall, *Chemical composition, Chlorides, Nitrates, Sulfates, Magnesium, Potassium, North-West England, England.

Measurements of the chemical composition of rainwater and suspended particles collected in parallel at a rural site in North-West England have shown that sulfate, nitrate, chloride, ammonium, sodium, magnesium, potassium, and calcium ions constitute the main ionic species in atmospheric aerosols and rainwater. Sodium and magnesium are associated with chlorides and originate from sea salt spray. Comparative concentrations in rainwater and parallel aerosol samples indicate that rainout and washout mechanisms are effective in the deposition of sea salt aerosols at this sampling site. Acidity was only present to any appreciable degree in rainwater samples. It appears that at least in this region where the levels of NH3 in the lower atmosphere are usually high and annual rainfall is appreciable, the deposition of acidity is mainly due to wet deposition. Washout and principally rainout mechanisms are efficient in the removal of anthropogenic sulfur compounds. (Baker-IVI)

CHEMICAL COMPOSITION OF WATERBODIES IN THE ENGLISH LAKE DISTRICT: RELATIONSHIPS BETWEEN CHLORIDE AND OTHER MAJOR IONS RELATED TO SOLID GEOLOGY, AND A TENTATIVE BUDGET FOR WINDERMERE,
Freshwater Biological Association, Windermere (England).
D. W. Sutcliffe, and T. R. Carrick.
Freshwater Biology, Vol. 13, No. 4, p 323-352, August, 1983. 13 Fig, 14 Tab, 87 Ref.

Descriptors: *Chemical composition, *Lakes, *Chlorides, *Sodium, *Ions, *Geohydrology, *Windermere, England, Pollution load, Water pollution sources, Groundwater budget, Groundwater pollution, Quantitative analysis.

It is well known that relative proportions and concentrations of most major ions in surface waters are basically dependent on the type of rocks and soils in the catchments. Sodium and chlorine ions are notable exceptions, particularly in maritime regions where it is believed these two ions are cyclically derived largely if not entirely from the oceans, via precipitation, and are concentrated in runoff by evaporation. Mean tarnwater concentrations of Cl(-) and other ions (Na(+), K(+), Ca2(+), Mg2(+), SO4(2-) + NO3(-))decrease with increasing distance from the sea and altitude but are related to solid geology. Lowest concentrations occur on slow-weathering igneous rocks (Borrowdale Volcanics); minima of c. 100 microequiv. Cl(-)/l are similar to the volume-weighted mean for bulk precipitation. At least 10-20% of Na(+) is leached from upland catchments, giving Na(+)/Cl(-) ratios greater than the equivalent ratio (0.86) in seawater and precipitation. Evapotranspiration at 20-30% annual rainfall accounts for Cl(-) concentrations in many tarns on igneous rocks but not all; some Cl(-) may be leached from the rocks in upland catchments and come from groundwaters at low altitudes near the sea. Seaspray has little influence on tarnwaters near the coast. On sedimentary rocks overall mean Cl(-) concentrations are 27-73% higher than equivalent means on Borrowdale Volcanics; concentrations of other ions are also higher. A 5-fold to 10-fold range of Cl(-) concentrations is not simply due to increased evapotranspiration. Na(+)/Cl(-) ratios are < 0.86, especially on Skiddaw Slates where tarn waters contain 10% or more excess Cl(-) balanced by Ca(2+), apparently derived from groundwaters rich in CaCl2. On other sedimentary rocks (Silurian Slates and Carboniferous, Triassic and Permian series) tarn waters display a similar but less pronounced excess of Cl(-) and Ca(2-)(+) relative to Na(+). Some extra Cl(-) may be captured by dry deposition on vegetation but a portion, perhaps 15-30% of the total, apparently comes from the rocks or from groundwaters via deep aquifers in contact with seawater or connate water. In anthropogenic sources on the catchments deicing salt used on highways in winter accounts for a 27% increase of Cl(-) in Windermere South Basin over a 20-year period. (Murphy-IVI)

THE CONTRIBUTION OF HUMIC SUBSTANCES TO THE ACIDITY OF COLORED NATURAL WATERS,
Canada Centre for Inland Waters, Burlington (Ontario).
B. G. Oliver, E. M. Thurman, and R. L. Malcolm.
Geochimica et Cosmochimica Acta, Vol. 47, No. 11, p 2031-2035, November, 1983. 1 Fig, 2 Tab, 31 Ref.

Descriptors: *Acidity, *Water analysis, *Humic acids, Wetlands, Groundwater, Nova Scotia, Rivers, Lakes, Streams, Fulvic acids.

Many natural waters contain low concentrations of dissolved solids, have low conductivity and possess little alkalinity, so they are highly susceptible to the effects of acid precipitation. An operationally defined carboxy content of humic substances extracted from rivers, streams, lakes, wetlands, and groundwaters throughout the United States and Canada is presented. Despite the diversity of the samples, only small variations were noted in this humic carboxyl content. The dissociation behavior of two combined fulvic-humic acid extracts was studied and the dissociation of the humics varied in a predictable manner with pH. Using a carboxyl content of 10 microeq/mg humic organic carbon, and mass action quotient calculated from sample pH, the ionic balances of three highly colored Nova Scotia rivers were examined. The acidity contribution of humic substances to a watershed was concluded to be equivalent to the carboxylate anion concentration and so can be estimated for colored or dystrophic waters by these procedures. A portion of the acidity may be released in weathering and/or ion exchange reactions in the watershed's soils or sediments. Once the humic materials reach the watercourse, further hydrogen ions may be released through dissociation. This acidity may be present as free hydrogen ions in the water or may be consumed by neutralization reactions in the watercourse. (Baker-IVI)

ACID PRECIPITATION - AN INTERNATIONAL ENVIRONMENTAL PROBLEM,
Norsk Inst. for Vannforskning, Oslo.
L. N. Overrein.
Water Science and Technology, Vol. 15, No. 12, p 1-7, 1983. 5 Ref.

Descriptors: *Acid rain, *International environmental effects, Environmental effects, Sulfur compounds, Nitrogen compounds, Metals, Industrial development Air pollution, Europe, North America.

Acidification is a trans-World problem. The concept of acidification is bound up with the discharge into the atmosphere of sulfur dioxide, nitrogen oxides, and metals and other micropollutants, and the subsequent effects of these substances on the environment. The bulk of man-made emissions occurs over industrialized regions covering less than 5% of the earth's surface. In these regions, man-made emissions exceed the natural emissions by a factor of five to twenty. In the 1950's a sharp rise in oil combustion increased the SO2 emissions in Europe to about 25 million tons of sulfur per years by 1970. European emissions of NO sub x have increased from low values 100 years ago to the present value of about 6 million tons of nitrogen per year. Similar emission trends of SO2 and NO sub x have taken place in North America. Sulfur dioxide emissions in Europe are predicted to remain about the same as present day emission through 1990. Further trends in emission will depend critically on the energy policies of each country and the entire region. Strong acids have decreased the mean annual pH of precipitation in much of Northwestern Europe and large areas of North America to between 4 and 4.5. The sources and environmental consequences of acid deposition are often separated by hundreds, even thousands, of kilometers. The emission source areas exposed to the heaviest depositions will be facing serious

direct and indirect effects on natural ecosystems, materials and possibly even human health. Further, metal toxicity in soils, surface waters and groundwaters with consequences for terrestrial and aquatic life will most likely develop in both heavily polluted and sensitive areas. (Murphy-IVI)

THE ROLE OF SOIL IN DETERMINING SURFACE WATER COMPOSITION,
Macaulay Inst. for Soil Research, Aberdeen (Scotland).
B. W. Bache.
Water Science and Technology, Vol. 15, No. 12, p 33-45, 1983. 6 Fig, 1 Tab, 21 Ref.

Descriptors: *Soil properties, *Surface water, *Water properties, Chemical properties, Groundwater, Surface drainage, Rainfall impact, Mineralogy, Physiochemical properties.

The composition of major rivers and large lakes is variable within certain limits, and on a world scale follows a logical pattern controlled by the interplay of three mechanisms, atmospheric precipitation, rock dominance and evaporation-crystallization processes. Incoming precipitation in rural areas passes through soil and weathering rock during passage to surface waters. The composition of the effluent is determined by its hydrologic pathway and by the material through which it flows. Reactions between water and soils or weathering rocks are normally rapid compared with typical residence times, so that the composition of water is derived from the material through which it has passed. Composition data for groundwater, drainage and surface waters illustrate these principles. Apparent deviations are explained by low residence times or unusual catchment properties, and show that detailed mineralogical and physiographic information is important for catchments in sensitive areas, if the factors controlling water composition in these areas are to be understood. EFFECT OF RAIN ON SURFACE REAERATION,
Asian Inst. of Tech., Bangkok (Thailand).
R. B. Banks, G. B. Wickramanayake, and B. N. Lohani.
Journal of Environmental Engineering, Vol. 110, No. 1, p 1-13, February, 1984. 4 Fig, 5 Tab, 9 Ref.

Descriptors: *Aeration, *Rain, *Oxygen transfer, Turbulence, Rainfall rate, Air-water interfaces, Dissolved oxygen.

For any river or lake or other body of water, the atmosphere is the primary source of dissolved oxygen in the water. Any mechanism which creates turbulence at or near a water surface will tend to increase the rate of oxygen transfer across the surface. It seems apparent that rain falling on a body of water is a mechanism for the creation of surface turbulence. The energies of raindrops striking the water create cavities, droplets, and surface waves. This phenomenon was examined by conducting 108 laboratory experiments. Test variables were rainfall rate, raindrop diameter and impact velocity, rotational velocity of a mixing impeller, and collector tank depth. The oxygen transfer coefficient is directly proportional to the power of the rainfall. Heavy rainfalls over an extended period of time may contribute significantly to the overall oxygen balance in a body of water. The direct addition of oxygen from raindrops with oxygen concentrations at or near the saturation concentration can be an appreciable fraction of the total amount of oxygen transferred as a consequence of the rainfall. DISTRIBUTION AND ABUNDANCE OF ZOOPLANKTON IN AN ALKALINE FRESHWATER MARSH IN NORTHUMBERLAND COUNTY, PENNSYLVANIA,
Bucknell Univ., Lewisburg, PA. Dept. of Biology.
P. W. Seelbach, and W. F. McDiffett.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 3, p 379-395, 1983. 9 Fig, 33 Ref.

Descriptors: *Marshes, *Zooplankton, *Species diversity, Population dynamics, Distribution, Temperature effects, Acidity, Nitrogen, Phosphorus, Dissolved oxygen.

The zooplankton community of two ponds in an alkaline marsh in central Pennsylvania were studied. An open-water pond and an open-marsh pond were compared. The ponds were similar with respect to temperature, pH, dissolved oxygen, total dissolved phosphorus, nitrate-nitrite nitrogen, ammonium nitrogen and chlorophyll a. They differed significantly with respect to conductivity, alkalinity, habitat type, vegetation, depth and predation pressure. The open water pond contained cladocerans, cyclopoid and calanoid copepods and rotifers, all of which are common to open, limnetic waters. The nearby marsh pond contained cladocerans, cyclopoid copepods, ostracods and rotifers, all of which are common to littoral habitats. The marsh pond contained more species (35 to 25) than the open water pond, but also supported lower population densities. The zooplankton communities of the two ponds were distinctly different from one another with regards to species, but similar when only zooplankton types are considered. (Baker-IVI)

SPATIAL DISTRIBUTIONS AND HYPOTHETICAL GRAZING PRESSURES OF ZOOPLANKTON IN THE TIDAL, FRESHWATER POTOMAC RIVER,
American Univ., Washington, DC. Dept. of Biology.
C. Buchanan, and J. A. Schloss.
Journal of Freshwater Ecology, Vol. 2, No. 2, p 117-128, July, 1983. 4 Fig, 2 Tab, 27 Ref.

Descriptors: *Zooplankton, *Estuarine environment, *Potomac River, Tidal waters, Spatial distribution, Population dynamics, Stratification, Phytoplankton.

Zooplankton in the tidal, freshwater Potomac River were studied to determine whether they could indeed stratify and undergo diel vertical migrations and what grazing pressures could be expected of zooplankton populations in the freshwater reach during the summer of 1981. Four working hypotheses emerged from the study. Zooplankton were usually unstratified due primarily to tidal mixing and they did not undergo the classic pattern of diel vertical migration. Under certain tidal and light conditions, some zooplankton species could stratify in deeper waters for short periods of time. Consequently, the mean vertical distribution of grazing pressure in the water column was slightly skewed toward the bottom. The horizontal distribution of zooplankton in the river was very patchy, and may be due to slow and uneven lateral diffusion of waters after entering the Potomac River. During the summer of 1981, zooplankton populations could hypothetically filter 1.1% to 3.7% of the river volume per day on the average. Grazing pressure was lowest in the Potomac River just below the fall line, at the Memorial Bridge station. Grazing was as high as 9.7%/day in the downstream end of the freshwater reach. (Baker-IVI)

DYNAMICS OF PHYSICAL AND CHEMICAL PARAMETERS IN OKEFENOKEE SWAMP,
Louisville Univ., KY. Systems Science Inst.
R. W. Bosserman.
Journal of Freshwater Ecology, Vol. 2, No. 2, p 129-140, July, 1983. 9 Fig, 2 Tab, 12 Ref. NSF DEB 76-12292 and 78-08842.

Descriptors: *Chemical properties, *Physical properties, *Okefenokee Swamp, *Marshes, Oxygen, Organic compounds, Metals, Water level fluctuations, Temperature effects, Diurnal distribution, Climate.

During 1977 and 1978 diurnal and annual variations of physical and chemical parameters in a marsh within Okefenokee Swamp were examined. The general characteristics of physical and chemical parameters in Okefenokee Swamp marshes were similar to other blackwater ecosystems. Concentrations of dissolved metals are low while concentrations of organic compounds are high. The water is usually acidic with a pH that varies between 3.8 and 4.9. The water chemistry in the swamp is affected by the chemical, physical and biological factors which are dominant on different temporal scales. Climatic factors such as temperature, light, and precipitation are probably the major driving forces operating on an annual basis in the marsh. Water level changes occur on an annual scale because of changes in precipitation, evapotranspiration, inflows and outflows. Calcium, magnesium, and potassium ions are strongly correlated with water levels. During droughts, when water levels are near zero, the marsh environment is drastically altered. Oxygen falls to concentrations near zero, while other elements are elevated. (Baker-IVI)

MANGROVE DISTRIBUTION IN NORTHWESTERN AUSTRALIA IN RELATIONSHIP TO REGIONAL AND LOCAL FRESHWATER SEEPAGE,
V. Semeniuk.
Vegetatio, Vol. 53, No. 1, p 11-31, July, 1983. 12 Fig, 7 Tab, 25 Ref.

Descriptors: *Mangrove swamps, *Tidal flats, Australia, Hydrology, Seepage, Natural waters, Salinity, Groundwater properties, Stratigraphy.

The field studies conducted illustrate the relationship between mangrove distribution and a variety of physico-chemical factors such as tidal flat groundwater, freshwater input, and stratigraphy. The tidal flat stratigraphy is important in its relationship to the hinterland groundwater system and to hinterland drainage patterns, be they surface or internal types. It is this hinterland/tidal-flat stratigraphy that influences freshwater discharge into tidal lands and so has a marked effect on mangrove species distribution. Climate per se is important in that it may provide a short, intense, direct freshwater input and secondly it may regulate evaporation on the high tidal flats. However, long-term freshwater input flowing for most of the dry season will be a far more effective and influential control on mangrove distribution. A freshwater reservoir lies within the hinterland, but the fresh water requires pathways through which it can invade hypersaline groundwater fields if it is to influence mangrove distribution. Analysis of the stratigraphic/hydrologic framework is therefore of importance to understanding mangrove development and zonation, particularly along the landward fringe, because it provides the key to understanding mechanisms of these subterranean freshwater incursions. GRADIENT ANALYSIS OF THE VEGETATION OF THE BYRON-BERGEN SWAMP, A RICH FEN IN WESTERN NEW YORK,
Ithaca Coll., NY. Dept. of Biology.
J. M. Bernard, F. K. Seischab, and H. G. Gauch, Jr.
Vegetatio, Vol. 53, No. 2, p 85-91, September, 1983. 4 Fig, 1 Tab, 24 Ref. NJF Grant DED-7809340.

Descriptors: *Vegetation, *Fens, *New York, *Byron-Bergem Swamp, Species diversity, Detrended correspondence analysis, Soil properties, Organic matter, Peat, Marl, Hummocks, Swamps.

Transects of contiguous one square meter quadrats were sampled across the marl and peat mosaic of the Byron-Bergen swamp, a rich fen in western New York. The data were analyzed by detrended correspondence analysis (DCA). The ordination successfully separated sedge fen from marl fen vegetation in spite of the high beta diversity (6.99) and further separated hummock from encroaching

forest sites. Neither of these separations was accomplished by alternative ordination techniques. Detrended correspondence analysis offers a significant advantage over reciprocal averaging and earlier ordination techniques for the study of within- and between-community pattern because of its superior performance with long vegetation gradients (more than 4 or 5 half-changes as observed in this study and indicated by the high beta diversity shown). DCA serves to convert species composition data into a vegetational variable whose patterns can then be compared with environmental patterns in order to generate hypotheses about the causes of within-community vegetation patterns. ENVIRONMENTAL GRADIENTS AND BENTHIC MACROINVERTEBRATE DISTRIBUTIONS IN A SHALLOW NORTH CAROLINA ESTUARY,
National Marine Fisheries Service, Beaufort, NC. Beaufort Lab.
A. J. Chester, R. L. Ferguson, and G. W. Thayer.
Bulletin of Marine Sciences, Vol. 33, No. 2, p 282-295, April, 1983. 6 Fig, 7 Tab, 42 Ref.

Descriptors: *Estuarine environment, *Benthos, Aquatic life, Invertebrates, North Carolina, Estuaries, Distribution, Sediments, Tidal effects.

Environmental gradients and distributional patterns of benthic macroinvertebrates were studied using multivariate statistical analyses in subtidal sediments of a shallow, southeastern United States estuary. Along a major estuarine gradient from fine anaerobic sediments, rich in organic matter and pheopigment to coarse aerobic sediments high in ATP and chlorophyll biomass and numbers of individuals increased significantly. A second environmental gradient within the lower estuary linked high numbers of invertebrates to depositional areas near salt marshes and low numbers to turbulent regions adjacent to deep, tidally-scoured channels. Invertebrate species composition was spatially associated with both environmental gradients. Seasonal patterns of abundance and biomass varied in the estuary, possibly due to differential predation on the dominant species. The observed sediment distributions were consistent with results of earlier studies. (Baker-IVI)

FRESHWATER IMPACTS IN NORMALLY HYPERSALINE MARSHES,
San Diego State Univ., CA. Dept. of Biology.
J. B. Zedler.
Estuaries, Vol. 6, No. 4, p 346-355, December, 1983. 4 Fig, 4 Tab, 13 Ref. NOAA grant NA80AA-D-00120.

Descriptors: *Salt marshes, *Floodwater, *Rainfall, Marshes, Saline water, Environmental effects, Flooding, Saline soils, Biomass, Halophytes, California, Tijuana Estuary, Los Penasquitos Lagoon, San Diego River.

Southern California salt marshes usually have hypersaline soils, but heavy rainfall in 1978 and 1980 caused flooding. Freshwater effects were correlated with the degree of change in soil salinity. At Tijuana Estuary (1980), a short-term reduction in the salinity of normally hypersaline soils was followed by a 40% increase in the August biomass of Spartina foliosa. At Los Penasquitos Lagoon (1978), a longer period of brackish water influence was followed by a 160% increase in August biomass of Salicornia virginica. At the San Diego River (1980), flood flows were augmented by major reservoir discharge. Continuous freshwater flow leached most of the marsh soil salts and caused replacement of halophytes by freshwater marsh species. The first two cases fell within the normal range of flooding events, even though the hydrology of both watersheds has been modified. The vegetation response was functional. The productivity increased but there was no major change in species composition. The vegetation rapidly returned to preflood conditions. However, the long-term freshwater flow in the San Diego River was unnatural. Floral composition changed as soils were leached of salts. Recovery following the return of saline soils has been slow because many native halophytes are not good colonizers. Southern California salt marshes are resilient to flooding, but artificially prolonged flooding can cause shifts in composition from which the marsh will recover slowly if at all. Management for the maintenance of natural salt marsh communities must include management of the watershed's hydrology so that the timing and duration of fresh water discharges do not exceed the threshold for compositional changes. TRANSIENT HYDRODYNAMIC AND SALINITY SIMULATIONS IN THE CHESAPEAKE BAY NETWORK,
Thatcher Research Associates, Inc., Palisades, NY.
M. L. Thatcher, and T. O. Najarian.
Estuaries, Vol. 6, No. 4, p 356-363, December, 1983. 7 Fig, 2 Tab, 20 Ref.

Descriptors: *Salinity, *Bays, Saline water intrusion, Estuaries, Harbors, Chesapeake Bay, Model studies, Atlantic Ocean, Tidal hydraulics.

The temporal and spatial variations of salinity in upper Chesapeake Bay and its tributaries are of interest to water resource planners. Many characteristic estuarine processes are related to the salinity gradients in the system. Also, such gradients affect the magnitude of the non-tidal circulation in estuaries and partially determine the spatial distribution of the resident fauna and flora in the system. Calibration of a model was based on only three external parameters: a friction factor that was spatially described, and two global constants required to calibrate a dynamic dispersion relationship that depended on both the local salinity gradient and hydraulic conditions. The transient hydrodynamics and the transient salinity distribution of the Bay and its tributary estuaries were simulated for the period of one month and comparisons were made between calculated and observed salinities. The dynamics of salt transport in the Bay proper are sensitive to local freshwater inflows. The simulations of salinity during August-September 1969 indicate that, whereas salinities in the lower Bay have an initial decreasing trend due to large freshwater inflows, the trends in the upper Bay are increasing due to the low freshwater inflows from the Susquehanna River during this period. It was not possible to fully verify the capability of the model in simulating the transport of sea salts from the Bay to the tributary estuaries, due to the lack of synoptic data on the salinity concentrations in the tributaries. (Baker-IVI)

THE REPRODUCTIVE CYCLE OF THE BAY SCALLOP, ARGOPECTEN IRRADIANS IRRADIANS (LAMARCK), IN A SMALL COASTAL EMBAYMENT ON CAPE COD, MASSACHUSETTS,
Woods Hole Oceanographic Institution, MA.
R. E. Taylor, and J. M. Capuzzo.
Estuaries, Vol. 6, No. 4, p 431-435, December, 1983. 4 Fig, 1 Tab, 17 Ref. NOAA grant NA80AA-D-00077.

Descriptors: *Estuarine environment, *Scallops, *Massachusetts, *Cape Cod, Shellfish, Hydrology, Spawning, Estuarine fisheries, Water temperature.

Because of its economic importance to coastal communities, an understanding of the dynamics of bay scallop populations is necessary for protection and for effective management of the fishery. The spawning activity of the bay scallop A. irradians irradians was monitored from May through September (1979) in a small embayment on Cape Cod, Massachusetts and compared with changes in hydrographic conditions. Spawning activity of bay scallops began in May and continued through July with some minor activity occurring during August and September. Activity was related to changes in ambient temperature and occurred predominantly before the summer maximum temperatures. As temperatures declined in the late summer and early fall, there was increased gametogenic activity. There was a longer period of spawning activity than previously reported for New England waters. (Murphy-IVI)

OBSERVATION OF EPISODIC SEDIMENTATION IN A TIDAL INLET (SABINE PASS, TEXAS AND LOUISIANA),
Espey, Huston and Associates, Inc., Austin, TX.
G. H. Ward, Jr.
The Texas Journal of Science, Vol. 35, No. 2, p 101-108, July, 1983. 3 Fig, 7 Ref.

Descriptors: *Episodic sedimentation, *Tidal inlet, *Sabine pass, Sedimentation, Tidal effects, Hydrometeorology, Coastal waters, Sedimentation rates, Sediment yield.

Sediment transport is not a constant process, but highly time variable and probably episodic, being dictated by such transient factors as tidal phase, wave climate, and the hydrometeorological regime. The sedimentation monitored with a recording tipping-bucket sampler in Sabine Pass, the inlet connecting Sabine lake (on the Texas-Louisiana boundary) and the Gulf of Mexico was episodic, characterized by events widely spaced in time. There was no apparent relation to astronomical tide, even at maximum declination. Sedimentation tended to be dictated by hydrometeorological factors. The most intense sedimentation episode of the study period (October and November 1978) was associated with the most energetic frontal passage. (Murphy-IVI)

CHEMISTRY OF DISSOLVED AND PARTICULATE MATERIAL IN THE ESTUARY OF THE RIMOUSKI RIVER (CONTRIBUTION A L'ETUDE CHIMIQUE DU MATERIEL DISSOUS ET PARTICULAIRE DE L'ESTUAIRE DE LA RIVIERE RIMOUSKI),
Quebec Univ., Rimouski. Dept. of Oceanography.
N. Belzile, and J. Lebel.
Marine Chemistry, Vol. 13, No. 1, p 15-34, 1983. 13 Fig, 2 Tab, 48 Ref.

Descriptors: *Chemical analysis, *Particulate matter, *Estuaries, *Rimouski River, Alkalinity, Pollution load, Natural flow, Residual chlorine, Fate of pollutants.

Suspended particulate matter (SPM) in the Rimouski River estuary contained dissolved oxygen, silicate, nitrate, phosphate, Mn, Fe and Al. At any given time, total alkalinity (TA) is conservative within the estuary with respect to chlorinity. The TA of the freshwater is related to river flow. This is attributed to dilution of the river water with bicarbonate-poor rainwater. Generally, pH follows the same pattern observed for TA in freshwater. Dissolved oxygen is usually more concentrated in freshwater and decreases linearly with increasing chlorinity. Freshwater is always saturated or supersaturated with respect to O2. Seasonal fluctuations are attributed to temperature variations. There is no evidence for removal of soluble silicate from the freshwater entering the sea. The concentration of silicate in the freshwater is strongly influenced by rainfall. Soil leaching, conditioned by high rainfall increases the concentration of soluble silicate in freshwater. Nitrate behaves similarly whereas phosphate is complicated by the presence of sewage. The Mn, Fe and Al contained in the SPM indicates dilution of river-borne particles rich in Mn by others less rich in this element. A decrease in Mn content with increasing chlorinity and SPM concentration as well as increasing concentrations of SPM with increasing chlorinity indicate that the composition is controlled primarily by physical mixing of material from two sources rather than by chemical processes. Within the ana-

lytical precision the Fe/Al ratio does not vary with the chlorinity. (Murphy-IVI)

D. Paelinckx, and R. Soetiens.
Bulletin de la Societe Royale de Botanique de Belgique, Vol. 116, No. 1, p 74-92, 1983. 3 Fig, 7 Tab, 22 Ref.

Descriptors: *s'Gravendel Nature Reserve, *Belgium, *Soil water, *Plant communities, Marshes, Heaths, Soil nutrients, Flooding, Minerals, Wetlands.

s'Gravendel is a marshy heath of 11 ha in the northwest of the Campine-district. Strong differences in intensity of earlier flooding with channelwater, rich in minerals, and smaller or larger differences in height cause a complex system of gradients in moisture and nutrient content. We find elements of the Magnocaricion in the wetter and more eutrophic parts of the area. Littorellion-communities occupy the other pools while the dryer ground is covered by Erica and Myrica heaths. NITROGEN LOSSES FROM A LOUISIANA GULF COAST SALT MARSH,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
R. D. DeLaune, C. J. Smith, and W. H. Patrick, Jr.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 2, p 133-141, August, 1983. 6 Tab, 17 Ref.

Descriptors: *Salt marshes, *Nitrogen, Louisiana, Gulf Coast, Estuarine environments, Coastal waters, Spartina alterniflora, Nitrogen cycle, Ammonium, Nitrification.

Nitrogen has been identified as the most important nutrient in regulating wetland macrophyte production. Ammonium is the predominant form of inorganic N found in the saturated sediment. Losses of N-15 labeled nitrogen were measured in a Spartina alterniflora salt marsh over three growing seasons. Labelled NH4(+)-N equivalent to 100 micrograms N/g of dry soil was added in four installments over an eight week period. Recovery of the added nitrogen ranged from 93% 5 months after addition of the NH4(+)-N to 52% at the end of the third growing season, This represented a nitrogen loss equivalent to 3.4 g N/sq m. By calculating the rate of mineralization it was possible to estimate the availability of the labelled NH4(+)-N incorporated into the organic fraction. The time required for mineralization of 1% of the tagged organic N increased progressively with succeeding cuttings of the S. alterniflora and ranged from 152 to 299 days. Only 2% of the nitrogen applied at N-15 labelled plant material to the marsh surface in the fall could be accounted for in S. alterniflora the following season. The findings of this study substantiate previous nitrogen studies conducted in this Louisiana Gulf Coast salt marsh. (Baker-IVI)

PLANKTON PRODUCTIVITY AND BIOMASS IN A TRIBUTARY OF THE UPPER CHESAPEAKE BAY. I. IMPORTANCE OF SIZE-FRACTIONATED PHYTOPLANKTON PRODUCTIVITY, BIOMASS AND SPECIES COMPOSITION IN CARBON EXPORT,
Academy of Natural Sciences of Philadelphia, Benedict, MD. Benedict Estuarine Research Lab.
K. G. Sellner.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 2, p 197-206, August, 1983. 1 Fig, 5 Tab, 37 Ref.

Descriptors: *Plankton, *Primary productivity, *Bays, Estuarine environments, Coastal waters, Chesapeake Bay, Phytoplankton, Carbon, Nanoplankton, Estuaries, Zooplankton, Cyanophyta.

Brackish-water tributaries are very productive with high planktonic productivity and faily extensive marsh communities supplying nutrients and organic matter. The contributions of inflowing organic matter and nutrients to the bay could conceivably lead to more eutrophic conditions for this large drainage system if the particulate materials are not utilized within the tributaries. Brackish waters of the lower Gunpowder River, a tributary of the Chesapeake Bay were the site of a 9 month study of phytoplankton productivity, community composition and biomass. Primary productivity followed expected seasonal magnitudes for temperate estuaries with rates exceeding 142.4 mg C/cubic m/hr in July through September of 1979. Minimum rates of 1.6 mg C/cu m/hr were noted in February of 1980. Annual primary production was estimated at 45.5 g C/sq m. Cyanophytes dominated the planktonic algae with cell numbers being highest in August, September and November. Nanoplanktonic forms dominated the primary productivity, chlorophyll concentrations and cell desnties throughout the study. Phytoplankton carbon calculated from cells volumes exceeded nutritional requirements of the pelagic herbivores in all months suggesting a mean daily export of 1607 mg C/cubic m/day to the bay or sediments. Thus the upper Chesapeake Bay may receive significant carbon influx as ungrazed phytoplankton cells, including high densities of procaryotic blue-green algae, from the lower Gunpowder River estuary. The fates of the ungrazed carbon and in particular the high procaryote densities in Chesapeake Bay remain to be determined. (Baker-IVI)

REDUCED RATES OF PRIMARY PRODUCTION IN THE COLUMBIA RIVER ESTUARY FOLLOWING THE ERUPTION OF MT. SAINT HELENS ON 18 MAY 1980,
Oregon State Univ., Corvallis. School of Oceanography.
R. E. Frey, J. R. Lara-Lara, and L. F. Small.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 2, p 213-218, August, 1983. 1 Fig, 2 Tab, 10 Ref.

Descriptors: *Environmental effects, *Primary productivity, *Columbia River Estuary, *Mt. Saint Helens, *Turibidity, *Volcanoes, Plankton, Columbia River, Phytoplankton, Light intensity, Light penetration.

A massive increase in suspended particulate material in the Columbia River Estuary resulted from the eruption of Mt. Saint Helens on 18 May of 1980 causing a substantial increase in light attenuation. Photosynthesis, being partly controlled by the depth of light penetration into the water, was reduced by about 75% during the period of increased turbidity. After about five weeks time the estuary was somewhat cleared. During this period the primary productivity in the estuary water column was greatly diminished. However, the flux of particulate carbon through the estuary was high. The total production estimated to have been lost amounted to only about 2% of the total particulate carbon flux just after the eruption. That the high levels of turbidity in the estuary did not induce a severe fall in the phytoplankton population is evidence that phytoplankton biomass concentrations in the Columbia River Estuary are mostly a function of import from the Columbia River, rather than a function of in situ production. Concentrations of organic seston, particulate carbon, and particulate nitrogen were all higher just after the eruption than during cruises 1-month earlier and 2-months later. This indicates that suspended sediment added to the estuary as a result of the eruption contained substantial quantities of organic matter. The food value of this material to estuarine organisms is not known. (Baker-IVI)

FLUORIDE POLLUTION IN FRENCH RIVERS AND ESTUARIES,
Ecole Normale Superieure, Paris (France). Lab. de Geologie.
J.-M. Martin, and F. Salvadori.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 3, p 231-242, September, 1983. 11 Fig, 2 Tab, 23 Ref. C.N.E.X.O. Grants 78/1937 and 79/2102.

Descriptors: *Fluoride, *Estuaries, *Rivers, France, Seine River, Gironde River, Charente River, Industrial wastes, Particulate matter, Loire Estuary.

Fluoride has long been considered as an acute pollutant to natural environment because of the ability of plants and marine organisms to accumulate it and because of its detrimental effects upon aquatic biota which can be affected by concentrations as low as 1.5 mg/l. The unpolluted estuary in the Loire has been compared with the Seine, Gironde and Charente where important discharges occur. Natural dissolved concentration can be multiplied by a factor of 30. In the Seine estuary fluorine particulate concentration reached almost 2000 ppm. Anthropic discharge did not influence the percentage between free and complexed dissolved fluoride. The present French rivers discharge of fluoride is 700% higher than the pristine value. At a global scale, dissolved fluoride has probably increased by 25% compared with the natural situation. TURBULENCE MEASUREMENTS IN STRATIFIED AND WELL-MIXED ESTUARINE FLOWS,
Hydraulics Research Station, Wallingford (England).
H. O. Anwar.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 3, p 243-260, September, 1983. 13 Fig, 1 Tab, 30 Ref.

Descriptors: *Turbulence, *Estuarine environment, Stratification, River Carron, Scotland, Velocity, Salinity, Buoyancy, Energy, Tidal currents, Flow characteristics, Stratified flow.

Velocity distributions were shown to be log-linear in stratified flows and logarithmic in well-mixed flows using mean velocities measured in estuarine flows. The mean salinity profiles are geometrically self-similar and expressible by a power-law. The drag coefficient remains constant at about .0032 in stratified case and is time dependent in well-mixed flow. The gradient and the flux Richardson numbers are almost equal, varying between 0.06 and 0.12, and independent of the flow state. The Monin-Obukhov length-to-depth ratio varies between 0.08 and 0.29. The non-dimensional parameter describing dissipation rates of turbulent kinetic energy remains a constant of about 0.2 and 0.3 for stratified and well-mixed flows, respectively. The nondimensional vertical turbulence coefficient varies between 0.5 and 1.7. The shape of the turbulent energy spectra and co-spectra of longitudinal and vertical velocity fluctuations in stratified flows are broader, and their maxima are lower than those of well mixed flows. (Baker-IVI)

APPLICATION OF NITROGEN-CYCLE MODEL TO MANASQUAN ESTUARY,
T. O. Najarian, P. J. Kaneta, J. L. Taft, and M. L. Thatcher.
Journal of Environmental Engineering, Vol. 110, No. 1, p 190-207, February, 1984. 10 Fig, 3 Tab, 16 Ref.

Descriptors: *Nitrogen cycle, *Manasquan Estuary, *New Jersey, *Estuarine environment, Mathematical models, Water quality, Hydrodynamics, Trophic level, Simulation.

A refined version of an ecologic and water quality mathematical model is applied to a small Atlantic coast estuarine network. The temporal and spatial variations in the water quality of the system are examined through the analysis of the nitrogen cycle developed for estuarine environments. The model is based on the mass conservation of elemental nitrogen in its various biotic and abiotic states. The ecologic model structure contains two trophic levels: primary producers, and herbivorous cope-

ods. A concerted effort is made to derive realistic model-governing transformations and rate parameters. The hydrodynamic and water quality model simulations are calibrated and verified using short-term, transient data gathered in the Manasquan Estuary and Point Pleasant Canal. Model verification for abiotic constituents of the nitrogen cycle is achieved, with biotic constituents verfication needing more detailed field data. Model results show the influence of transport processes on the temporal and spatial distribution of nitrogen-cycle constituents in the network examined. (Author's abstract)

3. WATER SUPPLY AUGMENTATION AND CONSERVATION

3B. Water Yield Improvement

AUGMENTATION OF RAINFALL FROM SUMMER CUMULUS CLOUDS,
Bureau of Reclamation, Denver, CO. Div. of Atmospheric Resources Research.
A. S. Dennis.
Agricultural Water Management, Vol. 7, No. 1-3, p 3-14, 1983. 3 Fig, 5 Tab, 24 Ref.

Descriptors: *Cloud seeding, *Cumulus clouds, *HIPLEX, Rainfall, Weather modification, Rainfall augmentation, High Plains, Montana, Cloud development, Dry ice.

The latest round of field experiments related to augmentation of rainfall from summer cumulus clouds over the Great Plains is described briefly. HIPLEX (High Plains Cooperative Program) was designed to reduce scientific uncertainty associated with attempts to increase rainfall by cloud seeding in the High Plains. Field programs were conducted at three sites. A randomized experiment, HIPLEX-1, was set up in Montana to test a physical hypothesis linking dry ice seeding to rainfall from cloud base. HIPLEX has confirmed the importance of ice processes to precipitation formation in cumulus clouds of the High Plains and the dominance of mesoscale convergence/divergence fields on convective cloud development. HIPLEX-1 clearly showed increases in cloud ice concentrations associated with dry ice seeding 2 and 5 min after treatment time. Some changes in the subsequent steps in the physical hypothesis linking seeding to increased rainfall at cloud base are indicated but cannot be firmly established with the present data set. (Author's abstract)
W84-03448

UTILIZATION AND ASSESSMENT OF OPERATIONAL WEATHER MODIFICATION PROGRAMS FOR AUGMENTING PRECIPITATION,
Colorado State Univ., Fort Collins. Dept. of Atmospheric Science.
L. O. Grant.
Agricultural Water Management, Vol. 7, No. 1-3, p 23-35, 1983. 1 Fig, 12 Ref.

Descriptors: *Weather modification, *Assessment, Cost-benefit analysis, Cloud seeding, Rainfall augmentation, Precipitation, Statistical analysis.

There have been and continue to be a significant number of operational weather modification programs for augmenting water supplies. The benefit to cost relationship for such programs is very favorable if even only modest changes in precipitation are produced. The incentive for these programs is particularly strong in the drier, western parts of the country and in all areas during drought periods. Evaluations and assessments are needed in any specific region to both confirm and establish the amount of precipitation change and to provide the basis for improvement in program performance. Interacting factors which must be considered in evaluation or assessing weather modification programs include aspects relating to the organizational, legal, assessment and integration components of such programs. Technical assessment should include assessment related to the operational efficiency of the program, physical studies to verify the occurrence of the chain of events expected from the seeding hypothesis employed, and statistical analyses to establish the changes in precipitation. Physical analyses by independent researchers superimposed on operational programs provide an unique opportunity to facilitate scientific research at less cost and provide significant technical input to the operational program. In such 'piggy back' research efforts, the pertinence of the findings to the operational program is direct, and the cost to the research can be significantly less. Randomization is highly desirable, but if full randomization is not acceptable, some compromises are feasible that can still permit scientific integrity of the analysis. (Moore-IVI)

Descriptors: *Irrigation water, *Cooling water, Powerplants, Water reuse, Water conservation.

The reuse of power plant cooling water for crop irrigation was examined for a period of 7 years. The first 3 years of study were conducted in 28 soil lysimeters containing four representative soil types from California. Alternate crops of winter wheat and sorghum were grown using three levels of total dissolved salts, 1,500, 3,000 and 6,500 ppm, which are within the range expected to be found in blowdown. Since the irrigation setup is so much less expensive to construct and maintain than a lined evaporation pond, this method of disposal could save a considerable amount of money. In the arid Southwest, more exotic crops, such as jojoba, guayule, and mesquite, may also be profitable when irrigated with blowdown water. (Baker-IVI)

FERTILIZER AND SALTY WATER EFFECTS ON PHASEOLUS,
Cornell Univ. Agricultural Experiment Station, Ithaca, NY. Dept. of Agronomy.
R. J. Wagenet, R. R. Rodriguez, W. F. Campbell, and D. L. Turner.
Agronomy Journal, Vol. 75, No. 2, p 161-166, March-April, 1983. 7 Tab, 23 Ref.

Descriptors: *Fertilization, *Saline water, *Phaseolus, Legumes, Saline soils, Irrigation effects, Nutrients, Nitrogen, Phosphorus, Irrigation management, Crop yield.

The response of legumes such as Phaseolus to adverse salt or water regimes is relatively unstudied as a function of soil nutrient status. Greenhouse studies, involving interactive effects on snap bean (P. vulgaris L.) yield of three levels of irrigation water salinity, three frequencies of irrigation water application, two levels of N applied in the irrigation water, and seven levels of P and K fertilization, determine if the adverse effects of saline conditions or water stress on Phaseolus could be overcome by enhanced fertility status and/or improved saline water management on an Argixeroll. Dry matter and bean yields were reduced with decreasing irrigation frequency (2 to 8 days) and increasing salinity of irrigation water (0.5 to 8.0 mmho/cm). Percentage yeild decrements were measured for both salt and irrigation regimes. Yield increases were noted for all fertilizer treatments so long as salinity did not become too high (8 mmho/cm). Plant N content and root weight were responsive to irrigation frequency and salinity, but not to fertilizer form. Nitrogen applied in the irrigation water produced increased yield across all treatment in one set of experiements where greenhouse conditions were hot, dry, and of high potential evapotranspirational demand. No N effect was measured in a second series of experiments with low potential ET. (Murphy-IVI)

EFFECTS OF WASTEWATER IRRIGATION AND PLANT AND ROW SPACING ON SOYBEAN YIELD AND DEVELOPMENT,
Michigan State Univ., East Lansing. Dept. of Crop and Soil Sciences.
M. J. Cordonnier, and T. J. Johnston.
Agronomy Journal, Vol. 75, p 908-913, November-December, 1983. 1 Fig, 5 Tab, 16 Ref.

Descriptors: *Wastewater irrigation, *Irrigation effects, *Cultivation, *Soybean yield, Municipal wastewater, Dry matter, Chemical analysis, water quality.

Considerable research has demonstrated that soybean 'Glycine max (L.) Merr.' yields can be increased with the addition of supplemental water during reproductive stages, but little information is available concerning the use of municipal wastewater as the water source. Variables included in this field study were: three water regimes-municipal wastewater, well water and no water; two row spacings-51 and 76 cm; two in-row spacings-20 and 32 plants/m and two cultivars-Nebsoy and Harcor. Soybeans planted on a Miami silt loam soil (fine-loamy, mixed, esic Typic Hapludalf) received a total of 9.8 cm of wastewater or well water as overhead spray irrigation in 1979 and 9.4 cm in 1980. Seed yields were significantly different for water treatments in 1979 with 2,430, 2,580, and 2,790 kg/ha for no water, well water and wastewater, respectively. Yields generally increased as plant population increased with the greatest yield for both cultivars occurring at the highest plant population (645,500 plants/ha). Irrigated plants were 4 to 5 cm taller, matured 5 to 6 days later, had larger seeds and lodge slightly more than nonirrigated plants. The two cultivars responded differently to the wastewater, with Harcor exhibiting a better response than Nebsoy. The 1980 growing season was wetter than normal and there was little or no yield response to irrigation. Under the conditions of soil type, climate and wastewater quality found during this experiment, wastewater was generally superior to well water in increasing yields. (Murphy-IVI)

LEACHING REQUIREMENT FOR SALINITY CONTROL III. BARLEY, COWPEA, AND CELERY,
Agricultural Research Service, Riverside, CA. Salinity Lab.
G. J. Hoffman, and J. A. Jobes.
Agricultural Water Management, Vol. 6, No. 1, p 1-14, 1983. 4 Fig, 4 Tab, 10 Ref.

Descriptors: *Leaching requirement, *Barley, *Cowpea, *Celery, *Salinity, Crop yield, Irrigation, Evapotranspiration.

Leaching requirement, the smallest steady-state leaching fraction which prevents any loss in crop yield, was determined for barley, cowpea, and celery in field plots at the U.S. Salinity Laboratory. Six replicated leaching-fraction treatments were irrigated many times each day with small quantities of water having an electrical conductivity of 2.3 dS/m. The crops were grown in succession between January 1979 and September 1981. The leaching requirement (Lr) was 0.10 for barley grain and 0.13 for barley forage. For cowpea seed, Lr was 0.16; 0.17 for cowpea forage, Lr for celery was 0.14. These experimentally determined values for barley and cowpea seed are higher by about 0.05 than those predicted by a leaching-requirement model based on an exponential crop water-uptake pattern. The experimental values for celery

and cowpea forage are lower than predicted values by 0.06. These differences are not considered significant, however, when considered in terms of the small differencs in water applications (about 25 mm) to cause these changes in Lr. Evapotranspiration during each crop's growing season coincident with Lr was 410, 630, and 460 mm for barley, cowpea, and celery, respectively. (Author's abstract)

3F. Conservation In Agriculture

RESIDUE MANAGEMENT AND CULTURAL PRACTICES FOR A SEMIARID REGION,
Agricultural Research Service, Big Spring, TX.
J. D. Bilbro, and D. W. Fryrear.
Journal of Soil and Water Conservation, p 312-314, May-June, 1983. 6 Ref.

Descriptors: *Water conservation, *Erosion control, *Residue management, *Semiarid lands, Crop residues, Infiltration, Soil erosion, Agricultural runoff, Wind erosion, Mulches, Cotton, Grasses.

In many regions of the United States, crop residue, if properly managed, can greatly minimize wind and water erosion and increase infiltration of precipitation. The use of applied mulches and residue grown in-place in the blank rows of the planting pattern of two rows of cotton alternated with two blank rows, and the use of perennial plants as wind barriers a top small, parallel terraces are two types of residue management. Three tons/acre of cotton gin trash and 4.5 tons/acre of millet residue applied as mulches to the blank rows of a two by two pattern in 1982 increased cotton lint yields by 47 lbs/acre, a 24% increase and 144 lbs/acre (90%), respectively. Additional quantities of either mulch did not significantly increase lint yields. Growing either millet or pigweeds in the blanks of a two by two pattern in 1982 reduced lint yields drastically and by essentially the same amounts, regardless of whether the millet and pigweeds were mowed two, four, five or six times from June through September. Lint yields of plants adjacent to the millet and pigweed plots were reduced by an average of 112 lbs/acre (69%) and 162 lbs/acre (93%), respectively. All millet and pigweed plots, except those that had been mowed after July 27, had enough residue on February 10, 1983, to prevent wind erosion. A 27.5 inch-wide band of the native grass Texas panicum produced enough residue in 1982 to keep soil losses in the adjacent 56 feet below 5 tons/acre if the erosive winds are perpendicular to the band of grass. Single rows of Ermelo lovegrass and Kleingrass Sel. 75 atop small, parallel terraces spaced 62 feet apart did not significantly affect lint yield of cotton grown between the terraces. A single row of Aztec Maximilian sunflower reduced yields 38%. The two grasses adequately protected the 62 foot interval from erosion by perpendicular winds. The less dense sunflower barrier would protect no more than a 40 foot interval. (Murphy-IVI)

SIMULATING THE EFFECTS OF WEATHER VARIABLES AND SOIL WATER POTENTIAL ON A CORN CANOPY TEMPERATURE,
Agricultural Research Service, Phoenix, AZ. Water Conservation Lab.
B. Choudhury.
Agricultural Meteorology, Vol. 29, No. 3, p 169-182, 1983. 6 Fig, 29 Ref.

Descriptors: *Soil water potential, *Canopy, *Plant water potentials, Evaporation, Water loss, Irrigation, Temperature effects, Soil properties, Corn, Plant growth, Leaves, Water potential, Water stress, Soil-water-plant relationships.

It has long been recognized that plant temperatures can be used as an indicator for soil water status. When the plant available soil water decreases, the canopy temperature increases. A soil-plant-atmosphere model based on the solution of Monteith's and van den Honert's equation for transpiration is used to study the dependence of corn canopy temperature on weather variables, soil water potential and rooting density. For unstressed canopies, air and dewpoint temperatures appear as the significant weather variables affecting the canopy temperature during a significant portion of clear-sky day periods. The present simulation gives a quasi-linear relationship between the canopy-air temperature difference and the air vapor pressure deficit. The relationship, however, is found to depend on the rooting density and hence on the soil strength. The canopy-air temperature difference values at lower soil water potentials are linearly related to the same values at field capacity, the coefficients (intercept and scope) of this relationship being dependent on the soil water potential through the crop water stress index. The variation of crop water stress index with the soil water potential is given for a silt loam soil. The stomatal resistance function is a pivoting relationship in a soil-plant-atmosphere model. INCIDENTAL EFFECTS OF AGRICULTURAL WATER CONSERVATION,
California Univ., Davis. Dept. of Land, Air and Water Resources.
D. C. Davenport, H. J. Vaux, Jr., and R. M. Hagan.
California Agriculture, Vol. 37, No. 3 and 4, p 28-31, March-April, 1983. 3 Fig, 1 Tab.

Descriptors: *Water conservation, *Agriculture, Irrigation practices, Farming, Cost analysis, Economic aspects, Management, Water quality, Water supply.

Over 400 potential incidental effects of agricultural water conservation actions are identified and divided into 23 categories. Identification of an incidental effect does not always show the magnitude of its importance, which depends partly on local conditions and partly on the extent of the water conservation action. Energy related effects occur both on and off the farm, depending on the specific conservation action and source of water. In general, the most pertinent on-farm effects are those related to farm net returns including production input factors, such as energy, fertilizer, labor, management, and other production costs and those related to production output, namely crop responses to water quantity and quality, to pathogens, to pests and the risks associated with conservation actions that affect the yield of marketable produce. Most of the 23 categories of incidental effects identified have both private and external impacts. Methods of estimating both private and external technological costs and benefits are well developed both conceptually and theoretically. Recognition of some incidental effects may give growers additional incentives to conserve water. (Baker-IVI)

IRRIGATION SCHEDULING UNDER SALINE HIGH WATER TABLES,
California Univ., Davis. Cooperative Extension.
S. W. Kite, and B. R. Hanson.
California Agriculture, Vol. 38, No. 1 and 2, p 12-14, January-February, 1983. 4 Fig, 1 Tab.

Descriptors: *Soil salinity, *Soil water, *Salinity, Water table, Irrigation practices, Irrigation, Water supply, Leaves, Water potential, Water stress.

A technique has been developed for scheduling an irrigation program for a farm of 48 hectares in a saline high water table area. Maximum depth to the water table during the summer was about 4 feet. The electrical conductivity of the drainage water was about 4500 ppm, while that of the irrigation water was about 130 ppm. The soil type was mainly Armona clay for the top 10 inches. The rest of the soil profile was highly stratified with lenses of sand, silt or clay. Cotton was grown during the period of this project. An increase in irrigation intervals resulted in greater soil moisture depletion. Soil moisture depletion was greater when the pressure chamber was used for irrigation scheduling. Normally, intervals between irrigations under saline conditions should be smaller than those under nonsaline situations to minimize yield reductions. However, in this study the interval could be increased and it was suggested that soil moisture rather than soil salnity may have been the controlling factor for scheduling irrigations at that location. COMPUTER SCHEDULES IRRIGATION,
Montana State Univ., Bozeman.
J. Bauder.
Crops and Soils Management, Vol. 35, No. 8, p 15-17, June-July, 1983. 4 Fig.

Descriptors: *Irrigation practices, *Computers, Irrigation, Water supply, Rain gages, SCHEDULE, Soil water.

Proper irrigation scheduling is somewhat like keeping track of the balance of a minimum balance checking account, while at the same time trying to decide how much should go into savings and how much should go into checking. A computer program has been developed that can help a person keep track of the balance of water available in an irrigation system, tell how fast the water is being taken out by the growing crop, give the anticipated date when the minimum amount of water will be left in the system and the amount that should be added to replenish this amount. At the beginning of the growing season the irrigator establishes a file for his particular field. This file contains information on the crop to be grown, its date of emergence, and the type of soil involved. As the season progresses, the irrigator adds information on rainfall and other weather conditions. The computer calculates the rate of growth of the crop and the amount of water it will have used, then tells how much water should be left in the soil and when more will be needed. (Baker-IVI)

CROP YIELD - IRRIGATION RELATIONSHIPS IN A GYPSIFEROUS-SODIC SOIL,
Agricultural Research Organization, Bet-Dagan (Israel). Div. of Soil Physics.
D. Russo.
Agronomy Journal, Vol. 75, May-June, p 427-434, 1983. 6 Fig, 4 Tab, 15 Ref.

Descriptors: *Crop yield, *Irrigation effects, *Gypsiferous-sodic soil, Soil water suction, Salinity, Soil water potential, Bell pepper, Tomatoes.

Many desert soils in the Arava Valley of Israel contain appreciable amounts of stones, gypsum, and exchangeable Na, and very high salinity . Plant growth in such soils is dependent primarily on the possibility of leaching the soil prior to the growing season as well as on controlling the soil water content and salinity within the root-zone during the growing season. Three different amounts of water (in terms of pan evaporation) at two different irrigation frequencies (daily irrigation and irrigation every 3 days) resulted in different soil water suction and salinity profiles, each of which can be characterized by a time average and the variance about this average. Average (over

ne) soil water potential (ave psi) increased as
)th the amount of irrigation water (Q') and the
igation frequency (I) increased. For a given I,
e (ave psi)-Q' relationships can be described by a
perbolic function. In the gypsiferous-sodic soil
e salinity of the soil solution was highly correlat-
with the exchangeable Na of the soil, which, in
rn, was reduced with added irrigation water.
elative yields, Y, of the two crops were linearly
pendent on the variance of the soil-water poten-
l, independent of the irrigation regime. This
plies that the yield-soil-water potential relation-
ip can be described by a quadratic function. As
posed to the unique Y-(ave psi) relationships, the
-Q' relationships depend on the irrigation fre-
iency. For a given Q', yields of both crops ob-
ined under daily irrigation were higher than the
elds obtained under irrigation once in 3 days.
ighest fruit yields were 126.1 Mg/ha of tomatoes
d 62.7 Mg/ha of bell pepper; the respective
nounts of irrigation water were 1,013 and 2,164
m (109%) and 160% of the evaporation from a
lass A pan). (Murphy-IVI)

EAF AND CANOPY TEMPERATURES OF EARL MILLET GENOTYPES UNDER IRRI-ATED AND NONIRRIGATED CONDITIONS,
nternational Crops Research Inst. for the Semi-rid Tropics, Patancheru (India).
. Singh, and E. T. Kanemasu.
gronomy Journal, Vol. 75, p 497-501, May-June, 983. 5 Fig, 4 Tab, 19 Ref.

Descriptors: *Irrigation effects, *Leaf tempera-ures, *Canopy temperatures, *Pearl millet, Water tress, Plant water potential, Transpiration, Drought resistance.

Previous research reports that leaf and canopy emperatures correlate with the level of water tress in a plant. If genotypes of a given species iffer in their response to water stress, then leaf nd canopy temperatures could serve as indices of heir drought resistance. To test this hypothesis, 10 earl millet (Pennisetum americanum (L.) Leeke) genotypes differing in plant morphology were grown on a Eudora silt loam soil (fine silty, mixed, mesic, Pachic Haplustoll) under both irrigated and nonirrigated conditions. Leaf temperature (Tl), canopy temperature (Tc), canopy minus air temperature (Tc - Ta), leaf-water potential (psi sub l),leaf-diffusion resistance (LDR), water use (WU), and crop yields were observed in both irrigated and nonirrigated treatments. Significant differences ($P<0.05$) were in the grain yield, Tc, and Tc-Ta of genotypes, only in the irrigated treatment. Grain yield was negatively and significantly correlated with average afternoon Tc($r = -0.81$) and average afternoon Tc - Ta($r = -0.78$). Grain yield ratio (nonirrigated grain yield/ irrigated grain yield) was positively and significantly correlated with average afternoon Tl($r = 0.64$), average afternoon Tc($r = 0.64$), and average afternoon Tc - Ta($r = 0.75$). In the nonirrigated treatment, however, correlations of grain yield and grain yield ratio with various stress indices were insignificant. Average afternoon Tc and Tc - Ta was significantly correlated with average afternoon LDR only in the irrigated treatment. Average afternoon Tc and Tc - Ta in a nonstressed environment with an infrared thermometer could effectively be used as a technique to screen millet genotypes for their grain yield and grain-yield stability (nonirrigated grain yield/irrigated grain yield). W84-03251

FERTILIZER APPLICATION AND IRRIGATION MANAGEMENT OF BROCCOLI PRODUCTION AND FERTILIZER USE EFFICIENCY,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
J. Letey, W. M. Jarrell, N. Valoras, and R. Beverly.
Agronomy Journal, Vol. 75, p 502-507, May-June, 1983. 5 Fig, 4 Tab, 6 Ref. OWRT project B-203-CAL. WRC project UCAL-WRC-W-564. OWRT and USDI grant Public Law 88-379. California Water Resources Control Board contract 9-029-400-0.

Descriptors: *Fertilization, *Irrigation management, *Broccoli, Irrigation efficiency, Nitrogen, Furrow Irrigation, Crop yield, Irrigation effects, Evapotranspiration.

Fertilizer and irrigation must be managed for efficient resource use and preservation of environmental quality as well as maximum production. Two furrow irrigation experiments growing broccoli (Brassica oleracea) were conducted. The first consisted of three N rates (90, 180, and 270 kg/ha), two irrigation treatments (replenishment of water lost by evapotranspiration and evapotranspiration plus 30%), and two N application procedures (application to the soil and in the irrigation water) on a sandy loam soil (coarse-loamy, mixed, thermic Typic Xerofluvent). Plant growth increased with increasing N application. For a given N application, there was higher average production with the lesser amount of water application. The method of N application had very little effect on production under the lower irrigation treatment, but production was consistently higher for N application with water rather than to the soil when the higher water application treatment was used. The ratio of N in the plant to N applied decreased with increasing N application, decreased with higher water application, and decreased with application in the irrigation water as compared to soil application. The second experiment consisted of two N rates (115 and 225 kg/ha) and two N application procedures (application to soil and in the irrigation water) on a loamy soil (fine-loamy mixed, thermic Calcic Haploxeroll). Yield and N uptake were significantly higher with 225 as compared to 115 kg/ha of N. Conventional preplant and side-dress N application to the soil resulted in significantly higher broccoli head yield than injecting N in the irrigation water. Leaching of N was not a factor under the experimental conditions. (Author's abstract)

EFFECT OF FOLICOTE ANTITRANSPIRANT APPLICATION ON FIELD GRAIN YIELD OF MOISTURE-STRESSED CORN,
New Mexico State Univ., Las Cruces.
H. D. Fuehring, and M. D. Finkner.
Agronomy Journal, Vol. 75, No. 4, p 579-582, July-August, 1983. 1 Fig, 2 Tab, 9 Ref.

Descriptors: *Folicote antitranspirant, *Crop Yield, *Moisture stress, *Corn, Antitranspirants, Environmental effects, Evapotranspiration, Transpiration, Drought, Moisture retention, Soil moisture retention, Optimum development plans.

Drought is one of the most important factors limiting the production of field crop. It has been established that the proportion of stomatal resistance to total resistance is less for carbon dioxide diffusion into the leaf than for water diffusion out of the leaf. Folicote, a hydrocarbon film-type antitranspirant, was foliarly applied on moisture-stressed field corn (Zea mays L.) grown on Pullman silty clay loam (fine, mixed, thermic Torrertic Paleustoll) soil. Single seasonal applications (foliar spray with ground rig just prior to tasseling) resulted in average yield increases of 11 and 17%. Fields where both the upper and lower leaf surfaces were sprayed required 1.93 L/ha for maximum yield responses, 42% less than required where spraying was from the top only. The response was curvilinear with definite yield depression when rates were too great, indicating the need to determine optimum application rates according to the method of application. It was concluded that antitranspirant application is a feasible method of increasing corn yield under the conditions of this study. (Murphy-IVI)

RESPONSE OF DRY BEANS TO DAILY DEFICIT SPRINKLER IRRIGATION,
Agricultural Research Service, Prosser, WA.
D. E. Miller, and D. W. Burke.
Agronomy Journal, Vol. 75, p 775-778, September-October, 1983. 1 Fig, 3 Tab, 9 Ref

Descriptors: *Beans, *Sprinkler irrigation, *Water deficit, Irrigation requirements, Water requirements, Soil moisture retention, Water stress, Soil texture.

Dry beans (Phaseolus vulgaris L.) are an important irrigated crop in the Pacific Northwest, but no information is available as to their water requirements under high-frequency sprinkler irrigation. The present study evaluates the response of dry beans to variable amounts of water applied daily by sprinkler, as affected by soil water-holding capacity. Studies were conducted on a Warden loam (coarse-silty, mixed, mesic Xerollic Camborthids) near Prosser, Wash., and on a Quincy sand to loamy sand (mixed, mesic Xeric Torripsamments) near Paterson, Wash. Irrigated was uniformly by solid-set sprinklers until near the time of full canopy, when irrigation variables were initiated and continued until harvest. On the loam soil yields were not reduced when daily sprinkler irrigation was much less than estimated evapotranspiration (ET). No more than 10 to 15 cm of water need be applied from full cover until harvest. On the sandy soil, yields increased with water applied up to the equivalent of nearly 100% estimated ET. On the sandy soil, with limited water holding capacity, it is not possible to reduce irrigation to much below estimated ET without loss in yield. (Murphy-IVI)

RESPONSE OF SOYBEAN CULTIVARS TO IRRIGATION OF A CLAY SOIL,
Agricultural Research Service, Stoneville, MS.
L. G. Heatherly.
Agronomy Journal, Vol. 75, p 859-864, November-December, 1983. 2 Fig, 6 Tab, 29 Ref.

Descriptors: *Soybeans, *Irrigation effects, *Clay soil, Soil texture, Soil water potential, Crop yield, Soil-water-plant relationships.

Numerous investigations have shown that soybeans 'Glycine max (L.) Merr.' will give a significant yield response to irrigation, especially when the supplemental water is applied during reproductive development. However, the majority of these results have been obtained with soils ranging in texture from silt loam to sandy loam. Since soybeans are frequently grown on finer-textured soils, we conducted field experiments in 1979 and 1980 on Sharkey clay (Vertic Haplaquept, very-fine, montmorillonitic, thermic), a soil representative of that occurring in about 3 750 000 ha of the alluvial plain of the Mississippi River. Variables included initiation of furrow irrigation at the prebloom (V), beginning of bloom (BL), beginning of pod set (PS), and beginning of pod fill (PF) stages, plus a nonirrigated (NI) treatment, and three cultivars representing Maturity Groups V ('Bedford'), VI ('Tracy'), and VII ('Bragg'). Data were collected for seed yield, mature plant height, lodging, xylem pressure potential, leaf area, and seasonal soil moisture status. In the 'wet' year of 1979, yields from irrigated Bedford and Tracy were not significantly greater than the respective NI yields of 2754 and 3368 kg/ha. The PF treatment of Bragg produced a yield of 36.30 kg/ha, however, and this was significantly higher than the yields of all other treatments of Bragg, as well as all treatments of Bedford. In the dry year of 1980, all irrigation treatments of all cultivars increased yields about the NI treatment, although the PF treatment yields were only about one-half of those from PB or BL treatments, which were nearly equal. Seed yield was highest from Bragg and lowest from Bedford

in all cases. Lodging was not significantly affected by any irrigation treatment. Mature plant height was significantly increased only in the BL treatment of Bedford in 1980. Measurements of xylem pressure potential, leaf area, and soil water potential in 1980 indicated that the NI plots were severly stressed; thus, response to irrigation should have been expected. Irrigation of soybeans growing in a clay soil should be initiated at or near bloom in a dry year, and at any period of stress during reproductive development in a 'wet' year. (Murphy-IVI)

Punjab Agricultural Univ., Ludhiana (India). Dept. of Soils.
P. R. Gajri, and S. S. Prihar.
Agricultural Water Management, Vol. 6, No. 1, p 31-41, 1983. 3 Fig, 6 Tab, 6 Ref.

Descriptors: *Crop yield, *Wheat, *Supplemental irrigation, Dry farming, Soil texture, Runoff, Water stress.

In dryland agriculture the amount of water accessible to crops depends upon the amount of stored water in the potential rooting zone and rainfall during the growing season. Where rainfall exceeds the water storage capacity of the soil or its intensity exceeds the infiltration capacity of the soil, the surface runoff may be collected during part of the year and stored for supplemental irrigation. Field experiments were conducted over a period of 4 years on loamy sand and 3 years on sandy loam to study the effects of pre-seeding, post-seeding and split application of limited amounts of water on dry matter accumulation and grain yield of wheat. Early season water stress decreased the rate of dry matter accumulation. Grain yield responded significantly to irrigation 30 days after seeding irrespective of the amount of water, year and soil type. Yield with post-seeding irrigation averaged 3518 kg/ha against 2317 kg/ha for unirrigated control in loamy sand and 4440 kg/ha against 3391 kg/ha in sandy loam. The increase in yield was manifested by a significant increase in the number of effective tillers per m row length, number of grains per ear and thousand grain weight. Under dryland conditions wheat yields can be increased and stabilized by a small irrigation of stored water. This irrigation is more crucial in coarse textured than in fine textured soils. For maximum benefit the stored water must not be applied until a few weeks after seeding in coarse textures soils. On finer textured soils the entire available water may be applied at the time of seeding. (Moore-IVI)

Descriptors: *Subsurface irrigation, Irrigation, Water supply, Netherlands, Water loss, Seepage, Groundwater flow, Water table, Model studies, Drought.

In humid areas such as northwestern Europe an excess of water occurs during winter. In the Netherlands, where drainage systems are usually well developed, damage to crops because of waterlogging of the soil rarely occurs, but during summer a water shortage may occur, caused by high evapotranspiration rates. In order to overcome possible damage from a water shortage in summer, the water level in the ditch and canal system in several areas is kept high by letting water in. Filling the drainage system with water causes an inflow into the soil, preventing a groundwater table drop, so the crops are fed by groundwater throughout the growing season. Subsurface irrigation is used in the northeastern part of the Netherlands to prevent drought damage to crops on reclaimed peat soils. Even so, high water losses due to deep seepage often prevent the building up of sufficiently high groundwater tables. Field data from a subsurface irrigation experimental field are presented to construct resistor network models to simulate the groundwater flow in the field and its surroundings. The model shows very good agreement with field data. Models were also used to simulate other conditions in order to detect the influence of ditch water levels and the effect of irrigation applied over a larger area. (Baker-IVI)

SOIL MANAGEMENT FOR SEMIARID REGIONS,
Minnesota Univ., St. Paul. Dept. of Soil Science.
W. E. Larson, J. B. Swan, and M. J. Shaffer.
Agricultural Water Management, Vol. 7, No. 1-3, p 89-114, 1983. 16 Fig, 1 Tab, 86 Ref.

Descriptors: *Semiarid lands, *Soil management, Water storage, Water use, Climate, Computer models, Simulation, Soil properties, Crop yield, Residue management, Tillage, Fallowing.

Water related climatic factors and soil physical and chemical properties exert a dominant effect on crop production in semiarid regions. Soil management practices which beneficially affect crop production by increasing water storage or through more efficient water use have been intensively studied at a number of locations with their associated soil conditions and under the climatic conditions encountered. The practical benefits of such research have been extensive. The application of field research to specific sites is restricted by the extreme variations in climatic conditions, by the large differences in soil physical and chemical properties, and by the variation in management practices which occur in the region. Because of these soil and climatic differences, the probability levels of expected responses to management practices generally have not been determined. Part of the difficulty has been due to the inability to precisely define and numerically describe the soil and climatic characteristics involved for sites and years other than those in which the research was conducted. Computer-based simulation techniques permit the development of long- and short-term site specific soil management recommendations with expected results expressed on a probability basis. The research results from specific geographic locations measured under a specific set of climatic conditions can thus be generalized to a much wider range of soils and expressed on a probability basis using long-term climatic records. Examples are given where crop yield frequencies are computed as a function of long-term climatic conditions involving various management practices. These results illustrate the impacts of a range of residue management, deep tillage, and fallowing practices on crop production in the semiarid environment. The modeling techniques presented can be used with a range of models and potential management practices. (Author's abstract)

PRINCIPLES OF WATER MANAGEMENT UNDER DROUGHT CONDITIONS,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
W. R. Gardner, and H. R. Gardner.
Agricultural Water Management, Vol. 7, No. 1-3, p 143-155, 1983. 8 Fig, 8 Ref.

Descriptors: *Water management, *Drought, *Dry farming, Crop yield, Summer fallow, Water harvesting, Surface water management.

In rain-fed agriculture the options for water management are much more limited than for irrigated agriculture and the management tools available to the farmer are few. The major variable at his disposal is the selection of the crop to be grown. The economic return per unit of water is the major factor to be considered. This usually implies the maximum possible ratios of grain or other harvested plant part to total dry matter. When the rainfall is just below amount needed for maximum dry matter production, this maximum can be achieved through appropriate manipulation of the plant population. The optimum population depends both upon the characteristics of the plant and the amount and distribution of the precipitation. When the amount of precipitation is significantly less than about 25% of the optimum, then other management approaches are required. A widespread solution to this problem has been summer-fallowing. However, in certain circumstances some variation on surface water management or water harvesting may be more advantageous. Criteria for decision making for optimum production under dry-land conditions are given. (Author's abstract)

IRRIGATION IN THE GREAT PLAINS,
Kansas State Univ., Manhattan. Dept. of Agronomy.
E. T. Kanemasu, J. L. Steiner, A. W. Biere, F. D. Worman, and J. F. Stone.
Agricultural Water Management, Vol. 7, No. 1-3, p 157-178, 1983. 4 Fig, 3 Tab, 102 Ref.

Descriptors: *Irrigation scheduling, *Great Plains, Soil water, Root zone, Evaporation, Transpiration, Hydrologic budget, Water stress, Economic aspects, Model studies.

Irrigation scheduling answers the question of when to irrigate and how much. The techniques used for scheduling include the monitoring of soil moisture, physiological indicators and water balance models. The areas of major concern are: a soil moisture sensor which is inexpensive, rapid and accurate; a means of assessing the upper and lower limits of soil water content in the changing root zone; development of a rapid technique for estimating leaf area; and a means of measuring canopy transpiration. A major research thrust than can be identified is the separation of evaporation from the soil surface and transpiration by the canopy. As one manipulates the canopy geometry to assess the culturral practices and irrigation systems, the need to clearly identify the contribution of evaporation and transpiration becomes increasingly important. The objective for irrigation for the farmer is to maximize his net returns. There are three components of an economic model for determining that decision: a water balance; a growth response function; and an economic optimization function. A few of the problem areas in such a scheme are: adaptation by the plant to water stress; dynamics of the root system; interaction between fertility and water; and risk analysis. (Author's abstract)

4. WATER QUANTITY MANAGEMENT AND CONTROL

4A. Control Of Water On The Surface

OPERATIONAL FLOOD ROUTING FOR HYDROELECTRIC PLANTS,
National Technical Univ., Athens (Greece). Dept. of Civil Engineering.
M. Mimikou.
International Water Power and Dam Construction, Vol. 35, No. 9, p 24-27, September, 1983. 2 Fig, 2 Tab, 8 Ref.

Descriptors: *Flood control, *Design criteria, *Powerplants, Construction, Model studies, Flood routing, Stochastic process, Hydraulic models, Greece.

A stochastic model is presented for transferring flood streamflows with lateral inflows. The model overcomes former difficulties and has been used successfully in the design and operation of hydroelectric plants. Calibration of hydraulic flood routing models is based on field information which is limited and extremely variable in space and time for most large natural streams. Thus, serious difficulties and inaccuracies are caused when hydraulic flood routing is used in such cases. The developed operational flood routing stochastic model can be calibrated with data from a very short period of time and successfully overcomes the hydraulic flood routing application difficulties. There are some limitations on the use of the model, such as when the flow velocity is needed, or there is no outflow information. The successful application of the model to several natural streams in Greece has shown its validity for the design and operation of hydroelectric plants. (Baker-IVI)

SHORT-TERM CLIMATE PREDICTIONS FOR WATER MANAGEMENT,
California State Dept. of Water Resources, Diamond Springs.
C. A. McCullough.
Bulletin of the American Meteorological Society, Vol. 64, No. 11, p 1273-1275, November, 1983.

Descriptors: *Short-term planning, *Climate, *Prediction, *Water management, Management planning, Forecasting, Water supply, Flood control, Reservoir releases.

Short-term climate predictions (two weeks to two years) have many applications to operation of water supply and flood control facilities. They influence use of water for irrigation, hydroelectric power production, flood control operation, recreational use of reservoirs, and numerous related water operations. The climate predictions now available have some limited usefulness. Those given an average skill factor of 65% can influence water management decisions. Short-term climatic predictions will be particulatly useful to operators of large water projects who must often base decisions for reservoir releases on expected weather conditions over the next 15-30 days. URBAN DESIGN-STORM SENSITIVITY AND RELIABILITY,
Prickett (Thomas A.) and Associates, Urbana, IL.
M. L. Voorhees, and H. G. Wenzel, Jr.
Journal of Hydrology, Vol. 68, p 39-60, 1984. 12 Fig, 5 Tab, 25 Ref. OWRT project A-095-ILL.

Descriptors: *Urban runoff, *Design storms, *Sensitivity, *Reliability, Computer models, Digital computers, Soil water, Model studies.

Urban-runoff design-storm selection has in the past been arbitrary at times, leading to inadequate and unreliable capacity design of urban-runoff structures. By utilizing a continuous urban-runoff digital computer model, the frequency response of selected urban basins to a selected historical point-rainfall record is generated. The model evaluates the sensitivity of the frequency response to design-storm parameters and antecedent soil moisture. This frequency response is used as a criterion for the selection of design storms. Sensitivity was exhibited by all the design-storm elements, confirming the feasibility of design storm reliability analysis Expectation analysis is applied to obtain estimates of reliable design storms. Expectation analysis yields reliable design storms. Application of expectation analysis to a two-parameter design-storm model is one practical recommendation. (Murphy-IVI)

ESTIMATING RESIDENTIAL FLOOD CONTROL BENEFITS USING IMPLICIT PRICE EQUATIONS,
Union Pacific Railroad, Omaha, NE.
E. Thompson, and H. H. Stoevener.
Water Resources Bulletin, Vol. 19, No. 6, p 889-895, December, 1983. 2 Tab, 10 Ref.

Descriptors: *Flood control, *Economic factors, Model studies, Mathematical equations, Land appraisals.

Estimating the value of changes in the quality of the environment has proven to be a difficult task. Public good characteristics typical of environmental attributes, such as the quality of the air, preclude the development of markets for these attributes. Without market transactions the economic value of environmental amenities cannot be observed directly. The application of implicit price equations to estimate the benefits from changes in the level of price determining characteristics such as air quality are numerous. However, empirical studies of flood control induced benefits are rare. An implicit price model relating residential lot value to price determining characteristics of land can measure the benefits of a structural flood control project. Special attention is given to the selection of relevant price determining characteristics of residential lots. An implicit price equation is estimated for both the with and without project conditions. Flood damages are quantified through the use of a dummy variable indicating a flood plain location. The analysis shows that annual flood damages were reduced by $15,275. Regression analysis results indicate that residential lots exposed to the flood hazards of Sutherlin Creek are valued less than lots not exposed to the threat of flooding. The value differential reflects the discounted value of expected damages associated with an unprotected flood plain location. Alternatively, it reflects the benefits derived from flood control. MICROCOMPUTER MODEL OF ARTIFICIAL RECHARGE USING GLOVER'S SOLUTION,
D. Molden, D. K. Sunada, and J. W. Warner.
Ground Water, Vol. 22, No. 1, p 73-79, January-February, 1984. 12 Fig, 9 Ref. Office of Water Resources Technology and Colorado State University Experiment Station project 1-51101.

Descriptors: *Computer models, *Artificial recharge, Discharge measurement, Groundwater recharge, Computer programs, Groundwater mounding.

An interactive program written for an APPLE II 48 microcomputer provides an analytical solution for recharge from a rectangular basin. R. E. Grover published in 1960 through the USDA Agricultural Research Service in Ft. Collins, Colorado, a paper offering a solution to mathematical derivations in groundwater recharge. This microcomputer model written in BASIC adapts Glover's solution to computerized application. The model is capable of graphically displaying the rise and decline of the recharge mound for either an infinite homogeneous medium or for a stream aquifer system. Using this program a large number of recharge strategies can be graphically worked out by hydrologists, including soil parameters and characteristics, plus unusual boundary conditions. (Wheatley-IVI)

Ground Water, Vol. 22, No. 1, P 86-93, January-February, 1984. 9 Fig, 17 Ref.

Descriptors: *Groundwater mounding, *Groundwater recharge, *Water level fluctuations, *Artificial recharge, Infiltration, Ontario, Norwood, Leaching, Mathematical models, Hydraulic loading.

An 84 m (276 ft) by 64 m (205 ft) experimental leaching bed was constructed to receive the secondary effluent from the Norwood, Ontario sewage treatment plant. The distribution system consisted of 100 mm diameter perforated pipes laid 2.1 m apart in 0.45 m wide trenches. The main soil layer at the test site was sandy silt. Ground-water levels at the site were measured approximately weekly at 36 piezometers for a period of about 2 1/2 years. An initial hydraulic loading of 122,700 l/day caused surface ponding. A reduced loading of 40,900 l/day was then used for most of the study period. Ground-water level fluctuations beneath and adjacent to the leaching bed were attributed to seasonally varying infiltration and hydraulic loading. The experimental data were simulated using a transient two-dimensional, phreatic integrated depth finite-element model and an analytic solution for ground-water mounding. Results from the study indicated that seasonal infiltration was a controlling factor in determining leaching bed design loads. Both mathematical models were found adequate for design. PRELIMINARY STUDY OF THE DIVERSION OF 283 CU M/S (10,000 CFS) FROM LAKE SUPERIOR TO THE MISSOURI RIVER BASIN,
Michigan Univ., Ann Arbor. Dept. of Civil Engineering.
J. W. Bulkley, S. J. Wright, and D. Wright.
Journal of Hydrology, Vol. 68, p 461-472, 1984. 2 Fig, 5 Tab, 13 Ref.

Descriptors: *Baseline studies, *Diversion, *Lake Superior, *Missouri River Basin, Groundwater depletion, Groundwater recharge, Diversion channels, Diversion structures, Economic aspects, Recharge Basins, Ogallala aquifer, Static head.

Trans-basin diversion is an established practice in this country. The High Plains Study authorized by the U.S. Congress in 1976 examined large-scale intra-basin diversion to replenish the depleted groundwater resources of the Ogallala aquifer. A portion of this intra-basin diversion could come from the Missouri River basin. This is the preliminary engineering associated with a large-scale diversion of Lake Superior water out of the Great Lakes and into the Missouri River basin in order to replace intra-basin water diverted for recharge of the Ogallala aquifer. The magnitude of the diversion is 283 cu m/s (10,000 cfs). The first cost of the conveyance structure is estimated at US $19.6 billion. The total length is estimated at 984 km and the total static lift including friction losses, static head, and pumping plant losses is 1130 m. An estimated 18 pumping plants will be required to lift the water from Lake Superior and transport it to the Missouri Basin. As estimated energy requirement to move this water is equivalent to the annual energy production from seven 1000-Mw plants. Initial costs of these power plants is estimated at $7 billion. Water Resources Bulletin, Vol. 19, No. 6, p 967-975, December, 1983. 9 Fig, 4 Tab, 5 Ref, 1 Append.

Descriptors: *Artificial recharge, *Columbia Basin Project, *Washington, *Groundwater irrigation, Surface irrigation, Energy costs, Cost analysis, Water importing, Water conveyance, Water distribution.

Appraisal-level, engineering economic analyses for two types of irrigation systems are compared: a surface-water irrigation system, and a groundwater recharge irrigation system. The study area is in the southern part of the Columbia Basin Project, where development of irrigable land is in the planning stage. The proposed plan is to import water from Franklin D. Roosevelt Lake in northeastern Washington through an extension of the East Low Canal and to apportion the water to farm units using a lateral distribution system. An artificial recharge irrigation alternative would divert water from the lateral system and deliver it to recharge facilities, using the same supply facility and canal extension. The aquifer would then be used to convey water to individual agricultural units for irrigation pumping. An artificial recharge irrigation system is an economically viable alternative to surface-distributed irrigation in a conjunctive irrigation plan if electric power rates remain sufficiently low. As electric rates increase, this viability generally decreases until it becomes completely unattractive at rates of about $0.012/kwh. (Moore-IVI)

CROSS-COMPLIANCE TO ENFORCE SOIL AND WATER CONSERVATION,
Wisconsin Univ.-Madison. Dept. of Urban and Regional Planning.
J. I. K. Wildmann.
Journal of Soil and Water Conservation, Vol. 38, No. 2, p 75-78, March-April, 1983. 1 Fig, 2 Tab, 20 Ref.

Descriptors: *Erosion control, *Cross-compliance, Planning, Conservation, Soil conservation, Water conservation, Soil and Water Resources Conservation Act, Legislation, Government finance.

Among the strategies proposed in the Soil and Water Resources Conservation Act process was cross-compliance. This strategy would require that farmers carry out a program of soil and water conservation acceptable to the US Department of Agriculture in order to participate in USDA's commodity, loan, and insurance programs. Such a policy raises several conservation policy questions. The advantages of cross-compliance include the avoidance of practices that cause erosion and sedimentation, thus yielding increased soil conservation benefits for all. New cropping and tillage combinations include minimum tillage, residue management, lengthening and changing crop rotations, and changing the timing of cultivation. Alternative land treatment practices include contouring, stripcropping, and terracing. Some practical problems inherent in the cross-compliance scheme are discussed. (Baker-IVI)

WHAT IS CONSERVATION TILLAGE,
Purdue Univ., Lafayette, IN. Dept. of Agronomy.
J. V. Mannering, and C. R. Fenster.
Journal of Soil and Water Conservation, Vol. 38, No. 3, p 140-143, May-June, 1983. 1 Fig, 5 Ref.

Descriptors: *Erosion control, *Soil conservation, Conservation tillage, Farming, Farm practices, Farm management, Tillage, Planning.

The suggestion is made that conservation tillage be used as an umbrella term, and that all tillage practices that conserve soil and water be listed under that term. Forms of row crop tillage include narrow strip tillage, no-tillage, strip rotary tillage, ridge planting, till-planting, full-width no-plow tillage, fall or spring chiseling, fall-spring disking, full-width plow tillage and wheel-tack planting. Forms of small grain tillage discussed include stirring and mixing machine tilling and stubble-mulch farming. People discussing conservation tillage are really talking about a system of farming. Equipment needs must be approached as a system based on soil and climatological conditions. The system must adequately control soil erosion, conserve moisture, and accommodate the crops grown. Weed, disease and insect control chemicals must be better understood. The fertility needs of crops grown with conservation tillage systems must be met efficiently. How conservation tillage affects labor and energy demands must be learned. (Baker-IVI)

CONSERVATION TILLAGE FOR EROSION CONTROL,
National Soil Erosion Lab., West Lafayette, IN.
W. C. Moldenhauer, G. W. Langdale, W. Frye, D. K. McCool, and R. I. Papendick.
Journal of Soil and Water Conservation, Vol. 38, No. 3, p 144-151, May-June, 1983. 4 Fig, 6 Tab, 25 Ref.

Descriptors: *Erosion control, *Soil conservation, Tillage, Farm management, Agriculture, Soil erosion, United States, Vegetation, Vegetation effects.

A region-by-region assessment is given of conservation tillage's effectiveness in controlling soil loss. In 1981 conservation tillage was used on one-third of the harvested cropland in the Corn Belt. The percentage of cropland in no-till was near the national figure of 2.5%. In the Corn Belt reduction of erosion seems to be a matter of leaving sufficient residue on the surface. In the Southeast it is important to break up the pan that forms each year in soil that is moldboard-plowed or even disked. Chiselling in the row breaks up the pan and allows moisture to get into the root zone, reducing runoff and erosion. In the Great Plains wind erosion is generally more serious than water erosion. Living or dead vegetation, again, is more effective than surface roughness in reducing erosion. Vegetation lifts the wind and also increases the percentage of nonerodible aggregates in conservation tillage practices. In the Pacific Northwest, growing vegetation effectively reduces erosion once the vegetation is established. No-tillage seeding of wheat has proved successful in reducing erosion, though under deep frozen soil conditions it may not reduce runoff. Surface roughness and surface residue prevent a continuous frost layer under shallow frozen soil conditions and help to reduce runoff. (Baker-IVI)

WATER QUALITY CONSEQUENCES OF CONSERVATION TILLAGE,
Iowa State Univ., Ames.
J. L. Baker, and J. M. Laflen.
Journal of Soil and Water Conservation, Vol. 38, No. 3, p 186-193, May-June, 1983. 4 Tab, 53 Ref.

Descriptors: *Water quality, *Water pollution sources, *Conservation tillage, Tillage, Erosion control, Soil conservation, Farm management, Vegetation, Agriculture, Runoff, Agricultural chemicals, Pesticides, Fertilizers.

Conservation tillage, which leaves some of all of the residue from the previous crop on the soil surface, effectively protects the soil against erosion. However, in order to maintain crop residues on the soil surface the use of fertilizers and pesticides is somewhat limited, affecting chemical concentrations and losses in surface water and sediment. Crop residue on the soil surface reduces runoff from all storms and eliminates runoff from most small storms. The slight to moderate reduction in runoff expected with conservation tillage

ystems will not alone have large impacts on the quality of receiving waters relative to chemicals ost in surface runoff. Of more importance in improving water quality is the soil conservation potential of conservation tillage and its impact on chemical losses with sediment. What impact conservation tillage has on chemical concentrations in runoff relates to the placement of agricultural chemicals during application and to the impact of conservation tillage on infiltration and runoff, particularly during the first storm after application, when most soluble losses occur. (Baker-IVI)
W84-03060

IRRIGATION + DRYLAND FARMING + LIMITED TILLAGE: A PROFITABLE COMBINATION,
Agricultural Research Service, Bushland, TX. Conservation and Production Lab.
A. F. Wiese, and P. W. Unger.
Journal of Soil and Water Conservation, Vol. 38, No. 3, p 233-236, May-June, 1983. 3 Fig, 4 Tab, 15 Ref.

Descriptors: *Erosion control, *Irrigation practices, *Crop yield, Economic aspects, Agriculture, Irrigation, Water conservation, Soil conservation.

Current research has produced new insights into methods of combining limited irrigation, dryland farming, and limited tillage into profitable conservation farming systems for the 1980s. Attempts have been made to exploit the advantage of mulch on the soil surface in the Southern High Plains. Because soil water storage and crop yields increased with an irrigated straw mulch and because not enough mulch could be grown under dryland farming conditions, it seemed logical that by alternating irrigated and dryland cropping, dryland crops could be forced to yield more. Several advantages have been noted through several studies performed in the Southern High Plains. Because of increased soil water storage, dryland crop yields not only increased, but crop failures were less frequent. Increased yields and lower production costs increased the profits. Finally, high levels of crop residue on the soil surface greatly reduced the threat of soil erosion by wind and water. (Baker-IVI)

LONG-TERM ANNUAL RUNOFF AND SOIL LOSS FROM CONVENTIONAL AND CONSERVATION TILLAGE OF CORN,
Agricultural Research Service, Columbia, MO.
R. E. Burwell, and L. A. Kramer.
Journal of Soil and Water Conservation, Vol. 38, No. 3, p 315-319, May-June, 1983. 5 Fig, 1 Tab, 14 Ref.

Descriptors: *Soil conservation, *Tillage, Runoff, Erosion control, Erosion, Missouri, Claypan, Soil loss, Corn, Farm management.

Conservationists recognize that maximum average soil loss rates that would permit maintenance of crop production need to be specified for conservation system design. A central Missouri claypan soil had runoff and soil loss for conservation tillage 85 and 42%, respectively, of that for conventional tillage. Annual soil loss was 54 and 63% of the average annual predicted soil loss for conventional and conservation tillage, respectively. Runoff for corn after corn using conservation tillage was 13% less than that for conventional tillage. Soil loss for corn after corn using conservation tillage was 58% less than that for conventional tillage. Average annual soil losses for both tillage treatments on a 27.4 m long slope were less than the T-value of 6.7 metric tons per hectare per year currently used in conservation planning. (Murphy-IVI)
W84-03064

RESIDUE MANAGEMENT TO REDUCE FURROW EROSION,
Agricultural Research Service, Prosser, WA. Irrigated Agriculture Research and Extension Center.
D. E. Miller, and J. S. Aarstad.
Journal of Soil and Water Conservation, Vol. 38, No. 4, p 366-370, July-August, 1983. 1 Fig, 7 Tab, 15 Ref.

Descriptors: *Erosion control, *Irrigation practices, Soil conservation, Water conservation, Tillage, Herbicides, Turbidity, Runoff, Erosion.

Proper use of crop residue is the most powerful tool available for reducing runoff, erosion and sedimentation. Controlled streams applied to irrigation furrows containing various amounts of plant residue controls erosion and reduces turbidity of runoff water. Nonuniformity of infiltration rates pose a problem along a furrow. The use of surge furrow inflow in combination with furrow residue to control erosion may improve infiltration uniformity. Relatively small amounts of residue effectively reduce erosion. Thus, limited tillage to prepare a seedbed and incorporate herbicides is possible, while leaving adequate residue in the furrows to control erosion. (Murphy-IVI)

SOIL CONSERVATION STRATEGIES IN THE THIRD WORLD,
National Coll. of Agricultural Engineering, Silsoe (England).
N. W. Hudson.
Journal of Soil and Water Conservation, Vol. 38, No. 6, p 446-450, November/December, 1983. 1 Fig, 1 Tab, 14 Ref.

Descriptors: *Soil conservation, *Developing countries, Water supply, Water conservation, Agriculture, Farming, Conservation, Soil erosion, Erosion control.

Third World countries are facing tough problems in the area of soil conservation that require different solutions than do problems in developed countries. An approximate picture of the erosivity of rainfall can be gathered from data sources around the world. But the data is far from complete in the region of the Third World countries. It is even more difficult to produce a worldwide comparative study of erodibility because of the lack of a universally applicable index of erodibility of the soil. The risk of high soil loss from steep land is compounded by inappropriate use of the land. Non-technical problems encountered in the developing nations include political problems, reserved land, legislation, social features, fragmentation, a social significance attached to cattle, and the reluctance to move. (Baker-IVI)
W84-03068

RUNOFF CURVE NUMBERS FOR CONSERVATION TILLAGE,
Agricultural Research Service, Beltsville, MD. Hydrology Lab.
W. J. Rawls, and H. H. Richardson.
Journal of Soil and Water Conservation, Vol. 38, No. 6, p 494-496, November/December, 1983. 1 Fig, 1 Tab, 19 Ref.

Descriptors: *Soil conservation, *Erosion control, Conservation tillage, Tillage, Conservation, Water conservation, Erosion, Runoff velocity, Runoff.

Conservation tillage effects on runoff vary. A new set of Soil Conservation Service runoff curve numbers reflect these effects, based on residue cover. The relative effectiveness of conservation tillage practices in controlling runoff depends on how much runoff velocity is reduced, how much surface storage is increased, how much conductivity and moisture storage is increased, and how much raindrop impact is reduced. The SCS procedure for predicting runoff uses total-event rainfall. The amount of residue left on the soil surface or the percentage of the soil surface covered by residue indicates the effectiveness of conservation tillage practices in reducing runoff. Conservation tillage causes a decline of 1 to 4 runoff curve numbers, translating into a reduction in runoff from 9 to 16% associated with fallow land in good hydrologic conditions. The 9% reduction is associated with small grain, contoured and terraced with a good hydrologic condition. (Baker-IVI)

EVALUATING RIPRAPPING AND OTHER STREAMBANK STABILIZATION TECHNIQUES,
California Univ., Berkeley. Dept. of Forestry and Resources Management.
J. R. McBride, and J. Strahan.
California Agriculture, Vol. 37, No. 5 and 6, May-June, 1983. 8 Fig.

Descriptors: *Bank stabilization, *Erosion control, Streams, Stream stabilization, Dry Creek, California, Sonoma County, Warm Springs, Russian River.

Stabilization of streambanks along creeks and rivers throughout Califonia is an important means of protecting agricultural land from erosion. Bank stabilization treatments have been installed in various locations along Dry Creek, primarily at meanders to absorb the erosional energy of the stream, deflect the current or both. The 14 mile long lower section of the creek, from Warm Springs Dam to the Russian River in Sonoma County was studied. Both the stabilization technique used and the harshness of the site determine the success of establishment. Bank stabilization with car bodies, wire fencing, and willow planting have not prevented the establishment of native riparian woodland species along Dry Creek. Wood fencing and the use of concrete rubble have led to the establishment of willow types without further successional development so far. Tire and rock riprapping and bamboo planting, however, have not provided environments where native riparian species can become established. Factors found to influence the establishment potential on stabilized areas include the erosional environment, available soil moisture, light, competition, position of the bank, and flow velocity. 5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

TOC DETERMINATIONS IN GROUND WATER,
Illinois State Water Survey Div., Champaign.
M. J. Barcelona.
Ground Water, Vol. 22, No. 1, p 18-14, January-February, 1984. 1 Fig, 4 Tab, 26 Ref.

Descriptors: *Organic carbon, *Groundwater pollution, *Pollutant identification, Chemical analysis, Volatile solids, Organic compounds, Monitoring.

Determinations of total organic carbon (TOC) can provide valuable diagnostic evidence of the extent of ground-water contamination by organic compounds. The usefulness of conventional TOC results in monitoring efforts is limited by the bias introduced during the purging of inorganic carbon prior to analysis. A modified TOC procedure permits the quantitation of the volatile organic carbon (VOC) fraction in water samples. The methodology consists of trapping the VOC in a manner analogous to commercial purge and trap instruments which are used for specific organic compound separations. The method is sensitive, accurate and reasonably precise for TOC determinations of standard solutions as well as on groundwater samples. Volatile organic carbon levels can range from 9-50% of the TOC in both uncontaminated and contaminated ground waters. The reporting of the volatile and nonvolatile fractions of the TOC will enhance both monitoring and research efforts, since it permits more complete characterization of the organic carbon content of groundwater samples. (Murphy-IVI)

RELATIONSHIPS BETWEEN GROUNDWATER SILICA, TOTAL DISSOLVED SOLIDS, AND SPECIFIC ELECTRICAL CONDUCTIVITY,
Agricultural Research Service, Fresno, CA. Water Management Research Lab.
B. A. Day, and H. I. Nightingale.
Ground Water, Vol. 22, No. 1, p 80-85, January-February, 1984. 4 Fig, 6 Tab, 19 Ref.

Descriptors: *Conductivity, *Groundwater, *Water quality, *Dissolved solids, *Silica, California, Fresno, San Joaquin Valley.

Specific electrical conductivity (SEC), total dissolved solids (TDS), and silica (SiO2) are groundwater quality parameters routinely measured in a laboratory. Electrical conductivity measurements are made quickly and are less costly than TDS measurements. Once the relationship between the parameters is determined by regression analysis, TDS can be estimated quickly from the SEC and SiO2 measurements. Water quality data from 25 city wells in Fresno, California, and historical ground-water quality data from the adjacent San Joaquin River/Kings River alluvial interfan (central San Joaquin Valley, California), the Kaweah River alluvial fan, and the Kern River alluvial fan (southern San Joaquin Valley) were used in this investigation. For the specific hydrologic areas studied, the model's TDS predictive ability is improved when SiO2 is included with SEC as the independent variables. (Author's abstract)

LONGITUDINAL DISPERSION IN NATURAL STREAMS,
Natural Systems Research, Hawthorn (Australia).
T. Beer, and P. C. Young.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1049-1067, October, 1983. 6 Fig, 48 Ref.

Descriptors: *Longitudinal dispersion, *Natural streams, Time series analysis, Pollution load, Comparison studies, Fikian model.

When time-series methods of parameter estimation are used to model the concentration of a pollutant in a natural waterway, the results may be grouped into a restricted class of models which are termed (j,n,m) models. The dispersion, as represented in conservative forms of these models, has a temporal variance that increases linearly with time (thus mimicking the variance of a Fickian process) and is consistent with dead zone mixing within rivers and streams. A variety of rivers demonstrate that the (j,n,m) model provides an explanation of actual data that is superior to those obtained by manipulation of a Fickian equation. In addition, the model greatly simplifies computation of dead zone dispersive effects, is able to simply deal with non-conservative pollutants and the results suggest that residence times are more meaningful physical parameters than dispersion coefficients in explaining dispersive phenomena. COMPARISON OF BASIN PERFORMANCE MODELING TECHNIQUES,
Espey, Huston and Associates, Inc., Austin, TX. Environmental Engineering Div.
G. F. Goforth, J. P. Heaney, and W. C. Huber.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1082-1098, October, 1983. 10 Fig, 6 Tab, 10 Ref.

Descriptors: *Comparison studies, *Basins, *Performance evaluation, *Model testing, Water pollution control, Storm water, Water management, Runoff volume, Stormwater detention basins, Drawdown, Drainage area.

Combined and separate storm sewer overflows contribute similar magnitudes of contaminant loads to receiving waters as does secondary treatment effluent. A comparison of methods used for analyzing the long-term pollutant removal efficiency in a stormwater detention basin points out some fundamental differences between simulation, using EPA's Storm Water Management Model, and a statistical technique advanced by Hydroscience, Inc. For the 24.6-yr record of Atlanta, Georgia hourly rainfall, the mean runoff event volume predicted by each method is similar. However, the inability of the statistical method to account for the reduction in the number of events (due to indigenous catchment storage) results in an estimate of total runoff 30% greater than the simulation results. The statistical technique employs a pollutant removal expression applied to the total flow captured in the detention basin, as contrasted to the simulation utilization of intra-event pollutant kinetics for removal within the basin. Solution surfaces of runoff flow capture and pollutant removal efficiencies are developed for each method as a function of basin volume and drawdown rate. The differences in performance estimates between the two methods increase as the basin volume and drawdown rate increase, with the statistical technique yielding the lower estimate of flow capture. For a long-term pollutant removal efficiency of 70%, the annual cost associated with a basin designed by the statistical technique is approximately twice that of a basin designed by simulation. The program SYNOP generates rainfall event statistics which may be incorporated with simulation, providing a coordinated approach for analyzing the performance of stormwater detention basins. SPECTROPHOTOMETRIC DETERMINATION OF NITRITE IN NATURAL WATERS BY FLOW INJECTION ANALYSIS,
Okayama Univ., Kurashiki (Japan). Inst. for Agricultural and Biological Sciences.
S. Nakashima, M. Yagi, M. Zenki, A. Takahashi, and K. Toei.
Analytica Chimica Acta, Vol. 155, p 263-268, December, 1983. 5 Fig, 1 Tab, 8 Ref.

Descriptors: *Nitrite, *Pollutant identification, Water analysis, Spectrophotometry, Flow injection, Natural waters, Lakes, Ponds, Irrigation water, Rain water, Well water.

Rapid, sensitive, and accurate methods of determining nitrite in natural waters are essential in environmental chemistry, geochemistry and limnology. This method is suitable for the determination of low microgram/liter levels of nitrite in waters. Nitrite diazotizes p-aminoacetophenone and the product is coupled with m-phenylenediamine at 30 degerees C. The limit of detection is 0.2 micrograms/liter for sample injections of 650 microliters. The sampling rate is about 30/hr and the relative standard deviation is less than 1.3%. This method was successful in determining nitrite at low micrograms per liter levels in natural waters taken from rivers, lakes, ponds, and wells as well as rain water and irrigation water samples. (Murphy-IVI)
W84-03109

ROUND ROBIN INVESTIGATION OF METHODS FOR THE RECOVERY OF POLIOVIRUS FROM DRINKING WATER,
Baylor Coll. of Medicine, Houston, TX.
J. L. Melnick, R. Safferman, V. C. Rao, S. Goyal, and G. Berg.
Applied and Environmental Microbiology, Vo 47, No. 1, p 144-150, January, 1984. 6 Tab, 30 Re

Descriptors: *Experimental design, *Poliovirus *Potable water, Water quality control, Water qua ity, Water analysis, Hydrologic data collection Adsorption, Viradel-organic flocculation, Filter Filtration.

Six laboratories actively involved in water virolo gy research participated in a methods evaluatio study, conducted under the auspices of the Ameri can Society for Testing and Materials Committe on Viruses in the Aquatic Environment, Tas Force on Drinking Water. Each laboratory exam ined the Viradel (virus adsorption-elution) metho with cartridge-type Filterite filters for virus ad sorption and organic flocculation and aluminum hydroxide-hydroextraction for reconcentration The quantity of virus recovered from four 100-lite samples of dechlorinated tapwater seeded with lov (350 to 860 PFU) and high (1,837 to 4,689 PFU doses of poliovirus type 1, were in considerabl variation. The Viradel-organic flocculatio method had an average percentage virus recover for low-input experiments of 66%, with a range o 8 to 20% in two laboratories, 49 to 63% in thre laboratories, and 198% in one laboratory. For th high-input experiments, two laboratories had re coveries of 6 to 12%, and four laboratories had recoveries of 26 to 46%. For the Viradel aluminum hydroxide-hydroextraction procedure, two labora tories recovered 9 to 11%, whereas four obtained 17 to 34% for low-input experiments. For the high input tests, two laboratories had a recovery of 3 t 5%, and four recovered 11 to 18% of the seeded virus. Each laboratory was also encouraged to tes other methods reported to be useful and reliable but which had not been widely used. Other meth ods tested such as magnetic iron oxide, 'Virozorb electropositive filters, Virozorb filters in combina tion with membrane filters, and membrane disks alone, had average virus recoveries of 36, 20, 0.4 and 5%, respectively. Possible differences in qual ity of the water in which the virus was diluted and in the quality of the eluents are some of the varia bles suspected for the wide differences in virus recovery results from different laboratories. Nev ertheless, there was sufficient consistency among four of the six laboratories for the task force to recommend the Viradel-organic flocculation pro cedure as a provisional method for the recovery of human enteroviruses from drinking water. A COLUMN TECHNIQUE FOR DETERMINING SORPTION OF ORGANIC SOLUTES ON THE LITHOLOGICAL STRUCTURE OF AQUIFERS,
Geological Survey, Menlo Park, CA.
D. F. Goerlitz.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 1, p 37-44, January, 1984. 2 Fig, 1 Tab, 15 Ref.

Descriptors: *Organic compounds, *Aquifers, *Pollutant identification, Contaminants, Chromatography, Groundwater pollution.

It is estimated that presently some 6.5 billion cubic meters of contaminated liquids infiltrate our ground water each year. Waste dumps and chemical impoundments are primary contributors to the contamination. There are apparent problems in the batch sorption determination and uncertainties in the indirect octanol-water partition, organic-carbon method. Alternative sediment-column technique uses readily available high performance liquid chromatography equipment thus permitting automation of the elution and effluent monitoring. This method was convenient, reproducible, and closely resembles ground water-transport mechanism. The sorption behavior of organic solutes in aquifer material was readily determined by evaluation of the elution histories of sediment columns. The heretofore difficult technique has been made practical through the use of high pressure liquid

hromatography technology. The ability to select solution concentration of column to the sediment est column permits wide flexibility for evaluation. The need for a minimum amount of attention uring the experiment is also a valuable feature of his technique. (Murphy-IVI)

BAKER'S YEAST ASSAY PROCEDURE FOR TESTING HEAVY METAL TOXICITY,
Florida Univ., Gainesville. Dept. of Environmental Engineering Sciences.
G. Bitton, B. Koopman, and H. D. Wang.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 1, p 80-84, January, 1984. Fig, 2 Tab, 14 Ref.

Descriptors: *Pollutant identification, *Water analysis, Yeast, Cultures, Heavy metals, Copper, Zinc, Mercury, Nickel, Silver, Metals.

As a result of the entry of thousands of chemicals into the aquatic environment, there is a need for rapid screening of chemical toxicity. A toxicity assay for heavy metals using commercial dry yeast as the test microorganism was most sensitive for copper and was intermediate in sensitivity for mercury, zinc, and nickel. Only in the case of mercury was the sensitivity of the bakers' yeast assay procedure less than 40% that of the most sensitive alternative toxicity assay. Bakers' yeast is readily available from commercial sources, is inexpensive and stable at room temperature for long periods. No tedious and time consuming culture technqiues are needed. The cells can be easily observed using a low cost compound microscope. (Murphy-IVI)
W84-03131

DETERMINATION OF CHLORINE DIOXIDE, CHLORINE, CHLORITE AND CHLORATE IN WATER,
Stanford Univ., CA. Dept. of Civil Engineering.
E. M. Aieta, P. V. Roberts, and M. Hernandez.
Journal of American Water Works Association, Vol. 76, No. 1, January, 1984. 7 Tab, 24 Ref. EPA grant R-808686.

Descriptors: *Pollutant identification, *Monitoring, Wastewater treatment, Chlorine, Chlorine dioxide, Chlorite, Chlorate, Drinking water, Disinfection, Water treatment, Titration, Potentiometry, Amperometry.

Chlorine dioxide is an attractive alternative for chlorine in drinking water disinfection, because it effectively inactivates bacteria and viruses over a broad pH range, does not produce trihalomethanes and provides a measurable residual. A procedure herein which is used for either amperometric or potentiometric determination of iodine is formed by the oxidation of iodide by chlorine dioxide, chlorine, chlorite, and chlorate. Either phenylarsine oxide or sodium thiosulfate can be used as the titrant. Sample pretreatment and pH adjustment differentiate among the various chlorine species. The method can be adapted to characterize either feed and product streams of chlorine dioxide generators (typical concentration range of individual species: 10-1000 mg/L) or treated drinking water (typical concentration range: 0.1-1 mg/L). The detection limits in drinking water are felt to be about 0.05, 0.02, 0.02, and 0.25 mg/L for chlorine dioxide, chlorine, chlorite, and chlorate, respectively. The sensitivity and precision represent a substantial improvement over other methods in use. In the high concentration range precision was good. In the low concentration range the method should prove helpful in monitoring the dosage of chlorine dioxide and in studying the transformations of oxidized chlorine species in treated waters and distribution systems. (Murphy-IVI)

RECULTIVATION OF LAKE MUTEK - ENVIRONMENTAL AND FISHERY ASPECTS,
Instytut Rybactwa Srodladowego, Olsztyn-Kortowo (Poland).
J. A. Szczerbowski, K. Lossow, H. Gawronska, S. Niewolak, and J. Sosnowska.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 2, p 103-140, 1983. 17 Fig, 6 Tab, 82 Ref.

Descriptors: *Lake Mutek, *Poland, *Environmental effects, *Lake fisheries, *Aeration, *Lake restoration, Chemical properties, Microorganisms, Phytoplankton, Macrophytes, Zooplankton, Benthic fauna, Aquatic environment.

Lake aeration and intensive fishery management allowed for better and more effective utilization of the existing production potential. The aeration process at Lake Mutek (1977-1980) prevented formation of the thermocline and increased temperature of over-bottom water layers to about 17 C. Lake aeration induced only slight changes in the sediments from shallow lake areas, accelerating processes of mineralization. The number of phytoplankton species decreased during aeration, while phytoplankton biomass doubled in 1978, increased four-fold in 1979, but decreased in the last year to levels lower than in the control year. The biomass of emerged and submerged vegetation increased by about 25%. The annual biomass of planktonic crustaceans almost doubled, and the vertical range of zooplankton occurrence became wider. The density and biomass of bottom fauna in the littoral and sublittoral zone noticeably increased, but in the profundal zone they decreased. Aeration, as a method of lake recultivation, had an effect upon physical and chemical properties of water, microorganisms, phytoplankton, macrophytes, zooplankton, bottom fauna and fishes. IDENTIFICATION AND DETERMINATION OF POLYCHLORINATED BIPHENYLS BY HIGH-RESOLUTION GAS CHROMATOGRAPHY,
National Water Research Inst., Burlington (Ontario). Analytical Methods Div.
F. I. Onuska, R. J. Kominar, and K. A. Terry.
Journal of Chromatography, Vol. 279, p 111-118, 1983. 3 Fig, 4 Tab, 11 Ref.

Descriptors: *Polychlorinated biphenyls, High-resolution gas chromatography, Computers, Chemical analysis, Water sampling, Pollutant identification, Sediments.

An integrated analytical procedure for polychlorinated biphenyl (PCB) multiresidues in sediment samples enables quantitation of PCB residues at levels as low as 0.1 microgram/kg in sediments. PCB residues are characterized and quantified by wall-coated open-tubular column gas chromatography with electron-capture detection. An automated data system, based on a Spectra Physics SP-4100 computing integrator, selects and quantitates peaks of individual isomers and homologous groups of PCBs. Interferences from the DDT group, organochlorine compounds and Mirex can easily be identified and subtracted from the chromatogram. The procedure consistently yields results with a reproducibility within 3%. (Murphy-IVI)

POSSIBILITIES AND LIMITATIONS OF TRACING INDUSTRIAL EFFLUENTS IN THE SEA BY MEANS OF CAPILLARY CHROMATOGRAPHY,
Chalmers Univ. of Technology, Goeteborg (Sweden). Dept. of Analytical and Marine Chemistry.
B. Josefsson.
Journal of Chromatography, Vol. 279, p 119-123, 1983. 1 Fig, 13 Ref.

Descriptors: *Tracers, *Effluents, *Chromatography, *Industrial wastes, Capillary chromatography, Water analysis, Seawater, Chlorophenols, Halogenated hydrocarbons.

Certain organic constituents of waste water, such as halocarbons and chlorophenols, can be used to establish the distribution pattern of effluents discharged into the sea. The approach requires simple sampling techniques and highly sensitive and rapid analytical methods. The combination of glass capillary column gas chromatography and electron-capture-detection meets the analytical requirements. The selectivity of the detector, together with the high resolving power of the column, makes it possible to handle the complex sea-water matrix. Selective derivatization directly in the water sample is combined with simultaneous extraction to increase the number of suitable tracers. Halocarbons can be measured at pg/l levels. Chlorophenols are determined at ng/l concentration levels. (Author's abstract)
W84-03158

DIRECT DETERMINATION OF TRACE AMOUNTS OF CHLOROPHENOLS IN FRESH WATER, WASTE WATER AND SEA WATER,
Chalmers Univ. of Technology, Goeteborg (Sweden). Dept. of Analytical and Marine Chemistry.
K. Abrahamsson, and T. M. Xie.
Journal of Chromatography, Vol. 279, p 199-208, 1983. 8 Fig, 2 Tab, 11 Ref.

Descriptors: *Chlorinated phenols, *Water analysis, *Wastewater analysis, *Seawater, Gas chromatography, Phenols, Pulp wastes, Drinking water, Acetylation.

Chlorophenols were acetylated and the derivatives extracted by the simultaneous addition of acetic anhydride and hexane directly to the water sample. The extracts were then analysed by glass capillary column gas chromatography with electron-capture detection. Determination of chlorinated phenols at micro g/l concentration levels requires only 5 ml of sample. At ng/l levels a 100-ml sample is sufficient. The total time of analysis is 18 min per sample. A comparison between pentafluorobenzoylation and acetylation showed that the acetylated derivatives of chlorophenol isomers separated better on the column. The method has been applied to drinking water, sea water and waste water from a sulfate pulp mill. (Author's abstract)
W84-03160

QUANTITATION OF ENVIRONMENTAL CONTAMINANTS BY FUSED-SILICA CAPILLARY COLUMN GAS CHROMATOGRAPHY-MASS SPECTROMETRY WITH MULTIPLE INTERNAL STANDARDS AND ON-COLUMN INJECTION,
Freshwater Fisheries Lab., Pitlochry (Scotland).
D. E. Wells, and A. A. Cowan.
Journal of Chromatography, Vol. 279, p 209-218, 1983. 1 Fig, 6 Tab, 14 Ref.

Descriptors: *Pollutant identification, *Gas chromatography, *Mass spectrometry, *Internal standards, Pesticides, Herbicides.

The on-column injector to the gas chromatographic-mass spectrometric (GC-MS) instrument had superior quantitative results when compared with the splitless injection, particularly for less volatile, non-polar herbicides and pesticides. The final sample solvent can be selected on the basis of the desired chromatographic separation to give shorter analysis times and minimal delay between injections. The precision in peak retention times and areas in markedly improved by the use of multiple internal standards, eluted within ten minutes of the analyte. Many of the internal standards selected may be used with GC-MS, gas chromatography-electron capture detection and high-performance liquid spectrometry with ultraviolet and fluorescence detection. (Murphy-IVI)
W84-03161

INVESTIGATION OF A COMPREHENSIVE APPROACH FOR TRACE ANALYSIS OF DISSOLVED ORGANIC SUBSTANCES IN WATER,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
M. Giabbai, L. Roland, M. Ghosal, J. H. Reuter, and E. S. K. Chian.
Journal of Chromatography, Vol. 279, p 373-382, 1983. 3 Fig, 3 Tab, 18 Ref.

Descriptors: *Organic compounds, *Water analysis, Drinking water, Natural waters, Trace substances, Adsorption, Gas chromatography, Hydrogen ion concentration.

An isolation-fractionation scheme for the analysis of dissolved trace organic substances in natural and drinking waters was developed. The principle behind this scheme was to concentrate dissolved organic solutes and separate them into fractions by adsorption on different adsorbents (XAD-8 resin, AG-MP-50 cation-exchange resin and Carbopack B graphitized carbon black) under varying pH conditions. Test solutions containing 22 model organic substances and inorganic salts were used to monitor process performance. High-resolution gas chromatography was employed for the separation and quantitation of each model compound. Chemical derivatization procedures were established for several highly polar model compounds. Gas chromatography-mass spectrometry was used for the confirmation of compound identity in each separated fraction. (Author's abstract)
W84-03162

EVALUATION OF SAMPLING METHODS FOR THE DETERMINATION OF TRACE ORGANICS IN WATER,
Alabama Univ., University. Dept. of Chemistry.
M. M. Thomason, and W. Bertsch.
Journal of Chromatography, Vol. 279, p 383-393, 1983. 5 Fig, 3 Tab, 27 Ref.

Descriptors: *Organic compounds, *Water analysis, *Gas-phase stripping, *Sampling, Solvents, Thermal desorption.

The applicability of a closed-loop gas-phase stripping apparatus for the determination of trace organics in water was evaluated. Recoveries were determined for a series of n-alkanes. The effects of extraction solvent, stripping temperature, stripping time, pH and salt content on the closed-loop system were investigated. Carbon disulfide was found to be the best extraction solvent, and an extraction temperature of 40 degrees C was found to be optimal. Two water samples spiked with 0.1-0.2 and 1.0-2.0 micro g/l of each U.S. Environmental Protection Agency base neutral priority pollutant were investigated. Recoveries for the base neutrals of the more concentrated sample were determined at 25 and 40 degrees C. A direct comparison of the closed-loop gas-phase stripping method and the purge-and-trap method with Tenax GC was performed on a river water sample. Recoveries for the thermal desorption of base neutrals from Tenax were determined at five different desorption temperatures. A new microextraction vessel, which allows the use of solvents heavier than water, was constructed and evaluated. Distribution coefficients and recoveries for compounds of different functionalities were determined at three different water to solvent ratios and at concentration levels of 100 ppb and 0.5 ppm. (Author's abstract)

RESEARCH IN ENVIRONMENTAL POLLUTION; I. DETERMINATION OF POLYCHLORINATED STYRENES (PCS'S) IN RHINE FISH,
Hessische Landwirtschaftliche Versuchsanstalt, Darmstadt (Germany, F.R.).
H. Steinwandter, and L. Zimmer.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 316, No. 7, p 705-710, December, 1983. 8 Fig, 7 Ref.

Descriptors: *Polychlorinated styrenes, *Rhine River, *Fish, *Pollutant identification, Polychlorinated biphenyls, Metabolism.

In chromatograms of extracts from fish from the Rhine River, in addition to chlorinated pesticides, the well know pattern of polychlorinated biphenyls can be seen. In the region of di-, tri- and tetrachlorobiphenyls the disappearance of certain polychlorinated biphenyl peaks indicates metabolic breakdown. The similarities between the ECD-chromatograms and HCB detect a very non-polar substance group to be present. By mass spectra and mass fragmentography the peaks were identified as polychlorinated styrene compounds. From 159 possible isomeric polychlorinated styrene compounds, 14 isomers were identified in fish. (Murphy-IVI)

BIOASSAYS WITH STIGEOCLONIUM KUTZ. (CHLOROPHYCEAE) TO IDENTIFY NITROGEN AND PHOSPHORUS LIMITATIONS,
Vrije Univ., Amsterdam (Netherlands). Biological Lab.
P. J. R. De Vries, M. Torenbeek, and H. Hillebrand.
Aquatic Botany, Vol. 17, No. 2, p 95-106, October, 1983. 3 Fig, 2 Tab, 37 Ref.

Descriptors: *Bioassay, *Stigeoclonium, *Nitrogen, *Phosphorus, *Nutrients, Chlorophyta, Eutrophication, Water quality, Seasonal variation, Polders, Netherlands.

In polder ditches, which are a characteristic of the Netherlands, eutrophication often results in abundant growth of periphyton and aquatic macrophytes. These organisms are the main producers and provide an indication of the water quality. Primarily for this aquatic environment, a suitable bioassay organism is needed and periphytic filamentous algae may be a useful addition to the range of test algae. Eleven strains of the filamentous algae genus Stigeoclonium were tested as bioassay organisms to identify nitrogen and phosphorus limitations to growth in a variety of waters. The assay results were related to the nutrient status of the waters during the year. Optimal growth was obtained at an inorganic phosphorus concentration of 0.65 mg P/l and an inorganic nitrogen concentration of 3.75 mg N/l. The algal growth potentials were generally higher in November and February than in August. Nitrogen became important as a limiting nutrient in the summer. When ratios of inorganic nitrogen to inorganic phosphorus (N/P) were above 6.2, phosphorus was primarily limiting and at lower N/P ratios nitrogen became the important limiting factor. Stigeoclonium proved to be a suitable bioassay organism to identify nutrient limitation in shallow freshwaters. (Moore-IVI)

A HIGH-SPEED LIQUID CHROMATOGRAPHY OF PHOSPHORUS IN ANOXIC WATERS OCCURRING IN A BAY USING SOLVENT EXTRACTION OF MOLYBDOHETEROPOLY YELLOW,
Hamamatsu Univ. (Japan). Dept. of Chemistry.
N. Ichinose, C. Shimizu, H. Kurokura, and T. Inui.
Fresenius's Zeitschrift fur Analytische Chemie, Vol. 316, No. 8, p 791-792, 1983. 3 Tab, 4 Ref. Japanese Scientific Research grant 1-R16-2.

Descriptors: *Chromatography, *Pollutant identification, *Phosphorus, Molybdoheteropoly yellow, Anoxic conditions, Lakes.

The deepest bottom of brackish water in lake Hamana of Japan forms an ocean basin. In this area anoxic waters are occurring in the summer with appreciable elutions of dissolved inorganic phosphorus, dissolved organic phosphorus, ferrous and ferric iron, soluble silica, hydrogen sulphide and other substances from the sludge in this anoxic waters. The application of high-speed liquid chromatography method can be widely employed for the rapid determination of microamounts of phosphorus, without the interference of co-existing silica, in sea and river water as well as anoxic waters. The interference of co-existing soluble silica is effectively eliminated by an extraction step. Micro-amounts of phosphrous ranging from 0.015 to 0.2 ppm in the anoxic waters can be determined rapidly and exactly (coefficient of variation 4.4%). The results agreed well with those obtained by spectrophotometry. (Baker-IVI)

A SIMPLIFIED 1,10-PHENANTHROLINE TECHNIQUE SUITABLE FOR THE DETERMINATION OF DISSOLVED IRON IN REMOTE SOUCES OF WATER,
Njala Univ. Coll., Freetown (Sierra Leone). Analytical Lab.
R. C. Wright.
Freshwater Biology, Vol. 13, No. 3, p 293-296, June, 1983. 2 Tab, 4 Ref.

Descriptors: *Iron, *Pollutant identification, Water quality, Remote areas, Sampling.

When testing remote water sources for dissolved iron, the investigator must either use a field method or reserve a sample for subsequent laboratory determination. The latter may produce a significant alteration in the relative amounts of the different iron fractions which occur in most samples. A simplified 1,10-phenanthroline technique is useful for investigating remote sources and avoids errors due to post-sampling precipitation of hydrated ferric oxides. A small sample is added to a mixed 1,10-phenanthroline + acetate buffer solution in the field and this developed sample can then be stored for up to 4 weeks before the absorbance value is read. Average within batch precision of the technique was about 4%. Accuracy was good for streams and river samples, although a relatively large negative bias was noted for shallow-pond sample replicates. (Baker-IVI)

METALS IN THE PACIFIC SARGASSUM ALGAE AS RELATED TO WATER POLLUTION MONITORING (METALLY V SOSTAVE TIKHOOKEANSKIKH SARGASSOVYKH VODOROSLEI V SVYAZI S PROBLEMOI MONITORINGA EAGRYAENENIYA VOD),
N. K. Khristoforova, N. N. Bogdanova, and L. M. Tolstova.
Okeanologiia, Vol. 23, No. 2, p 270-275, March-April 1983. 2 Tab, 27 Ref.

Descriptors: *Sargassum, *Metals, *Monitoring, Water pollution effects, Marine algae, Iron, Manganese, Copper, Zinc, Lead, Cadmium, Pacific Ocean.

The concentrations of the metals Fe, Mn, Cu, Zn, Pb and Cd, in sargassum are discussed in connection with the intensity of anthropogenic loading on their habitats. According to the mineral composition of algae, the quality of coastal waters of some Pacific regions is characterized. It is shown that Mn concentration in the algae depends on the illumination conditions rather than on the environmental geochemical factors, and that sargassums seem to be capable of regulating the accumulation of this metal. W84-03312

AUTOMATED RAIN SAMPLER FOR TRACE ORGANIC SUBSTANCES,
National Water Research Inst., Burlington (Ontario). Environmental Contaminants Div.
W. M. J. Strachan, and H. Huneault.
Environmental Science and Technology, Vol. 18, No. 2, p 127-130, February, 1984. 1 Fig, 2 Tab, 17 Ref. Department of Environment grant 9-904-EM-IWD.

Descriptors: *Measuring instruments, *Rainfall, *Organic compounds, Sampling, Water sampling, Polychlorinated biphenyls, Benzene hexachloride, Lindane, Chemistry of precipitation.

An automated rain sampler was designed, built, and evaluated as a collecting device for persistent organic chemicals in rain. It consists of a large Teflon-coated funnel (0.209 sq m) with an automated lid and a Teflon column containing XAD-2 and -7 resin. The sampler was tested for recoveries and field precision with a number of organochlorine substances and PCBs frequently found at the nanogram per liter level in rain. Recoveries averaged 86% and the mean coefficient of variation for alpha-benzene hexachloride, lindane, and polychlorinated biphenyl was 33% under field conditions where samples of 0.4-22 L of rain were collected. While few quality control studies have been attempted for this type of sampler, it is felt that these results are at least as good as those from any other technique. The sampler also offers the advantage of unattended operation for extended periods, and it provides a simple method for field handling of samples since the columns can be readily exchanged and capped for delivery. A MODEL OF THE DISPERSION OF SOLUBLE OF PSEUDO-SOLUBLE SUBSTANCES IN

WATERWAYS. APPLICATION TO THE CASE OF THE SEINE UPSTREAM OF PARIS (MODELISATION DE LA DISPERSION DES SUBSTANCES SOLUBLES OU PSEUDO-SOLUBLES DANS UN COURS D. EAU. APPLICATION AU CAS DE LA SEINE A L'AMONT DE PARIS),
Compagnie Generale des Eaux, Paris (France).
G. Bujon.
Houille Blanche, No. 1, p 45-53, 1983. 7 Fig, 4 Ref.

Descriptors: *Model studies, *Dispersants, *Solubility, *Waterways, *Seine River, Mathematical models, Mathematical studies, Simulation analysis, Pollution load, Flow characteristics.

Technicians working with water often have to anticipate changes in water quality at a given point in a waterway as a result of the permanent or temporary discharge of a polluting effluent upstream of this point. Since it is not generally possible to find a solution to this problem by experimental means (projections are often desired for low-level flow rates), it is necessary to resort to the use of mathematical simulation models, which are calibrated by means of a few preliminary experiments. The dispersion model is a bi-dimensional model established on the basis of the influence of the bands, a certain transverse variation in the field of flow speeds and the disappearance of part of the pollutant in the course of time. APPLICATION OF ULTRACLEAN SAMPLING AND ANALYTICAL TECHNIQUES TO AN INVESTIGATION OF THE IMPACT OF POWER-PLANT DERIVED HEAVY METALS ON GROUNDWATER, RIVERWATER, BOTTOM SEDIMENTS AND BENTHIC ORGANISMS,
Connecticut Univ., Groton. Marine Sciences Inst.
D. G. Waslenchuk.
Water Science and Technology, Vol. 15, No. 11, p 223-237, 1983. 4 Fig, 8 Tab, 12 Ref.

Descriptors: *Sampling, *Ultraclean sampling, *Analytical techniques, *Powerplants, *Heavy metals, *Groundwater, *Riverwater, *Bottom fauna, Mathematical analysis, Ecological effects, Trace metals, Geochemistry, Effluents, Cooling water, Sample preparation.

At a Massachusetts power station, the routine trace metal analyses provided by private water-quality laboratories gave the impression that metal levels in stream and groundwaters adjacent to the plant were alarmingly high. The problem though is more perceived than real. Ultra-clean sampling and handling techniques from geochemical oceanographic practices, together with interpretive concepts from aquatic geochemistry had levels of metal enrichment in stream waters which were lower (eg. Cu, 2 ug/l) than implied by the evidently investigator-contaminated samples (eg. Cu, 20ug/l). Employing difficult but uncompromising procedures when dealing with metals in the aquatic environment is extremely important. With accurate analyses at hand, the geochemist's 'mixing diagram' concept allows interpretation of the fate of the power-plant derived excess metals in the cooling-water discharge. Excess dissolved copper disappeares due to simple and rapid dilution in the effluent river mixing zone. For bottom sediments from the adjacent Connecticut River natural processes largely explain the distribution of Cd, Cr, Cu, Fe, Mn, Ni, Pb, and Zn associated with the acid leachable fraction of the sediments. No anomalous metal concentrations were among the sediments, but oligochaete worms living in the sediments beneath the cooling-water plume had accumulated more metal than those elsewhere. Because tissue metal levels were unrelated to sediment metal levels, the worms may respond more to the dissolved metal load than to the sediment burden. (Murphy-IVI)

RHODAMINE WT DYE LOSSES IN A MOUNTAIN STREAM ENVIRONMENT,
Geological Survey, Menlo Park, CA.
K. E. Bencala, R. E. Rathbun, A. P. Jackman, V. C. Kennedy, and G. W. Zellweger.
Water Resources Bulletin, Vol. 19, No. 6, p 943-950, December, 1983. 5 Fig, 4 Tab, 18 Ref.

Descriptors: *Tracers, *Dye releases, *Rhodamine dye, Mountain streams, Chloride, Lithium, Sorption, Streambeds, Gravel, Groundwater.

A significant fraction of rhodamine WT dye was lost during a short term multitracer injection experiment in a mountain stream environment. The conservative anion chloride and the sorbing cation lithium were concurrently injected. In-stream rhodamine WT concentrations were as low as 45% of that expected, based on chloride data. Concentration data were available from shallow 'wells' dug near the stream course and from a seep of suspected return flow. Both rhodamine WT dye and lithium were nonconservative with respect to the conservative chloride, with rhodamine WT dye closely following the behavior of the sorbing lithium. Nonsorption and sorption mechanisms for rhodamine WT loss in a mountain stream were evaluated in laboratory experiments. Experiments evaluating nonsorption losses indicated minimal losses by such mechanisms. Laboratory experiments using sand and gravel size streamed sediments show an appreciable capacity for rhodamine WT sorption. The detection of tracers in the shallow wells and seep indicates interaction between the stream and the flow in the surrounding subsurface, intergravel water, system. The injected tracers had ample opportunity for intimate contact with materials shown in the laboratory experiments to be potentially sorptive. It is suggested that in the study stream system, interaction with streambed gravel was a significant mechanisms for the attenuation of rhodamine WT dye (relative to chloride). (Author's abstract)

SEDIMENT SAMPLING IN DIFFERENT AQUATIC ENVIRONMENTS: STATISTICAL ASPECTS,
National Swedish Environment Protection Board, Solna.
L. Hakanson.
Water Resources Research, Vol. 20, No. 1, p 41-46, January, 1984. 3 Fig, 5 Tab, 26 Ref.

Descriptors: *Sediments, *Sampling, *Statistical analysis, Lake sediments, River sediments, Lead, Copper, Cadmium, Erosion, Sediment transport.

The study is based on empirical data from three different sedimentological environments: a river, a river mouth area, and a lake. The first two environments are dominated by processes of erosion and transportation; the latter milieu is characterized by continuous accumulation of fine materials. The empirical data emanates from a regular grid of nine sites 15 m apart from the three environments. The sediment were analyzed for physical sediment character (water content and loss on ignition) and chemical/contaminational status (Pb, Cu, and Cd). The prevalent bottom dynamics influence the character of the sediments and the representativity and information value of sediment samples. An informative fraction is defined by the portion of a sediment sample that passes a 63-micro m mesh by wet sieving. This fraction corresponds approximately to deposits from areas of accumulation. Direct analysis of surficial sediment samples from areas of erosion or transportation, such as in rivers and river mouths, yield low information, i.e., many samples would be required to obtain a given statistical certainty. Correction with the water content (or similar parameters, e.g. grain size and bulk density) or organic content would improve the information but still not yield optimal results. Simple wet sieving through a 63-micro m mesh seems to yield best information, i.e., the lowest number of necessary analysis for the least amount of work. Fractionated centrifugation (or similar approach, e.g., ultrafiltration) would not improve the information value. (Moore-IVI)

NONPARAMETRIC TESTS FOR TREND IN WATER QUALITY,
Washington Univ., Seattle.
G. van Belle, and J. P. Hughes.
Water Resources Research, Vol. 20, No. 1, p 127-136, January, 1984. 2 Fig, 5 Tab, 22 Ref, 1 Append.

Descriptors: *Water quality, *Trend, *Statistical analysis, *Nonparametric tests, Data analysis, Seasonal variation, Errors.

Nonparametric tests for trends in water quality have been developed because the assumptions of classical parametric methods (i.e., normality, linearity, independence) are usually not met by typical water quality data. Additional idiosyncrasies of the data, such as missing values, censored data, and seaonality, compound the analysis problem. The nonparametric methods are more flexible and can handle these problems more easily. Two classes of procedures, intrablock methods (procedures that compute a statistic, such as Kendall's tau, for each block or season and then sum these to produce a single overall statistic), and aligned rank methods (procedures that remove the block effect from each datum, sum the data over blocks, and then create a statistic from these sums) are examined in detail. Aligned rank methods are asymptotically more powerful than intrablock methods, but intrablock methods are more adaptable. Procedures to analyze more general models, including multistation designs and models, which include a trend-season or trend-site interaction, are developed by using Kendall's tau and intrablock methods. For the analysis of data sets with missing values and multiple values per season values, some possible solutions are adjustment of season length by using a uniform site series consisting of summary statistics, discarding extra observations, filling in missing observations with estimated values, or considering data collected in the same season as tied and using a modified version of tau. The appropriate procedure will depend on the individual data set, but basic statistical concerns include retention of the properties of homoscedasiticy (equal residual errors) and independence. (Moore-IVI)

ENTERIC VIRUSES IN NEW ZEALAND WASTEWATERS,
Otago Univ., Dunedin (New Zealand).
R. S. Simmonds, M. W. Loutit, and F. J. Austin.
New Zealand Journal of Science, Vol. 26, No. 4, p 437-441, 1983. 2 Tab, 19 Ref.

Descriptors: *Viruses, *Wastewater, New Zealand, Pollutant identification, Water treatment, Chlorination, Disinfection, Public health.

The most important disease-causing enteric viruses cannot be readily cultured from environmental samples, but the examination of water and wastewater for the presence of enteroviruses does provide a reliable indication of the presence of infectious virus. Samples from wastewater and treatment plants were tested for human enteroviruses after concentration by adsorption to and elution from bentonite. Nine different viruses were detected in 36 samples at concentrations ranging up to 4000 plaque forming units per liter. Included in the 9 were poliovirus types 1, 2, and 3; coxsackievirus types B2, B4, and B5; and echovirus types 21, 24, and 25. While virus numbers were reduced by chlorine treatment they were still detectable in 11 of the 16 chlorinated samples. Viruses were detected at considerable distances from the point of discharge, and the possibility of sporadic undetected infection exists. (Baker-IVI)

THE DISTRIBUTION AND ACCUMULATION OF ALUMINUM IN RAINBOW TROUT FOLLOWING A WHOLE-LAKE ALUM TREATMENT,
Eastern Washington Univ., Cheney. Dept. of Biology.
P. M. Buergel, and R. A. Soltero.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 37-44, March, 1983. 3 Tab, 11 Ref.

Descriptors: *Bioaccumulation, *Aluminum, *Rainbow trout, *Whole-lake treatment, *Aluminum sulfate, Ecological effects, Bioindicators, Lake restoration, Chemical analysis, Chemical composition.

Medical Lake, Spokane County, prior to 1977, was subject to high phosphorus concentrations manifested by reduced sediments. Phosphorus inactivation was accomplished by the appliation of 936 metric tons of alum (aluminum sulfate). The immediate and long-term effects of an alum treated environment upon the food chain are generally unknown. Because there has been a deliberate alteration in the natural chemistry of Medical Lake by the alum treatment, there is potential for a bioacumulation of aluminum by organisms inhabiting the lake. Because the fish and their prey are dependent upon a habitat potentially higher in available aluminum than neighboring habitats, trout tissues, plankton and water were analyzed for total aluminum concentrations. Statistical comparisons of experimental and control tissues revealed few overall significant differences ($P = 0.05$) in the level of aluminum between alum-exposed and non-exposed fish, but significant differences existed between tissues within a given treatment and age class. RUNOFF FRACTION AND POLLUTION LEVELS IN RUNOFF FROM A WASTE ROCK DUMP UNDERGOING PYRITIC OXIDATION,
Australian Atomic Energy Commission Research Establishment, Sutherland. Environmental Science Div.
J. R. Harries, and A. I. M. Ritchie.
Water, Air and Soil Pollution, Vol. 19, No. 2, p 155-170, 1983. 9 Fig, 1 Tab, 20 Ref.

Descriptors: *Rainfall-runoff relationships, *Acid drainage, *Mine wastes, Pyritic oxidation, Oxidation, Water pollution sources, Mine drainage, Dumps, Waste dumps.

A series of measurements was carried out during the 1975-76 and 1976-77 wet seasons, in which the rainfall incident on a waste rock dump, the fraction of rain that appeared as runoff, and the pollution levels in the runoff during runoff events were determined. Rainfall/runoff data was scattered about a curve that could be used to predict the average runoff response of the waste rock dump to rainfall on it. Although a runoff fraction as high as 33% was observed, the runoff fraction was in general quite low, with an average of 15% over the two wet seasons monitored in detail. Although the concentration of pollutants in runoff varied in a characteristic way throughout the discharge events monitored, there were insufficient data of sufficient precision to produce a well defined concentration level/runoff relationship for the dump that could be used in modeling the interaction between runoff water and the dump surface. Present data do show, however, that pollutant levels are largely insensitive to the rainfall pattern during the wet season and to the long rainless period during the dry season. The insensitivity of pollutant levels to the history of rainfall on the dump allows meaningful average pollutant levels to be evaluated and used to predict the annual pollutant load in runoff from the dump. STUDIES ON BACTERIOLOGICAL QUALITY OF NAINITAL LAKE WATER IN DIFFERENT SEASONS,
Kumaun Univ., Naini Tal (India). MAB/DST Lakes Project.
J. Pande, S. M. Das, and D. S. Misra.
Water, Air, and Soil Pollution, Vol. 19, No. 2, p 149-154, 1983. 1 Fig, 1 Tab, 9 Ref.

Descriptors: *Water quality, *Coliforms, *Bacteria, *Public health, Recreational water, India, Fecal contamination, Rain, Monsoons.

The density of total coliforms and E. coli in Nainital lake was measured in different seasons during 1978-79. The study was undertaken as a public health investigation as Lake Nainital is visited by more than 100,000 tourists each year and has a local population of 30,000. The raw water of this lake is used for domestic supplies as well as for recreational purposes by tourists and residents. The coliform count of entire lake water showed a distinct seasonal variation. The highest value of coliforms was observed during the rainy season while it was lowest in the winter months. It is believed that during the monsoon months the surface water drained from the surrounding areas of the lake probably added additional waste water from human habitation which could be the main cause for the high coliform count of lake water during the rainy season. This increase was probably due to increased human or animal activity. While there are no Indian Standards for recreational water quality, it is recommended that the total coliform count of 1000 and 5000/100 ml be the limiting values for contact and noncontact recreational waters, respectively, and that the corresponding values of 150 and 750/100 ml for E. coli be established for assessing the probable exposure to pathogenic organisms. The present high values of coliforms and E. coli of Nainital Lake could be considered a direct health menace, particularly in the summer season. (Baker-FRC)

PCB CONTAMINATION IN AND AROUND NEW BEDFORD, MASS,
Norwich Dept. of Public Utilities, CT.
G. Weaver.
Environmental Science and Technology, Vol. 18, No. 1, p 22A-27A, January, 1984. 1 Fig, 2 Tab, 5 Ref.

Descriptors: *Polychlorinated biphenyls, *Harbors, New Bedford, Massachusetts, Wastewater treatment facilities, Industrial wastes, Hudson River, Waukegan, Illinois, Bloomington, Indiana, Georges Bank.

New Bedford is the largest revenue-producing fishing port on the United States Atlantic seaboard. This community is bounded by the Acushnet River estuary, New Bedford Harbor, and Buzzards Bay. Past use of polychlorinated biphenyls has left a lasting effect on the vibrant port. Contamination of the Harbor was first noted in 1976. Testing revealed two industrial operations discharging wastewaters containing PCBs. Sediments underlying the entire 440 harbor contain elevated levels of PCBs. Widespread contamination of the Acushnet River estuary and environs resulted in the closing of the area to fishing. Located at the southern terminus of Clark's Point, the New Bedford wastewater treatment plant discharges a daily average of 10 to the 8th power liters of primary treated wastewater to Buzzards Bay. No decrease in PCB content is obvious following treatment. In addition to these sources of PCB contamination, other as yet unidentified dischargers exist. Some abatement procedures have been implemented but the fate of the extensive harbor water quality is still unknown. (Baker-IVI)

NONREVERSIBLE SORPTION OF PHENOLIC COMPOUNDS BY SEDIMENT FRACTIONS: THE ROLE OF SEDIMENT ORGANIC MATTER,
Connecticut Agricultural Experiment Station, New Haven.
P. J. Isaacson, and C. R. Frink.
Environmental Science and Technology, Vol. 18, No. 1, p 43-48, January, 1984. 6 Fig, 2 Tab, 29 Ref.

Descriptors: *Sediments, *Organic matter, *Phenols, Sorption, Hydrogen, Bonding, Chlorophenol, Dichlorophenol, Fate of pollutants.

The environmental fate of many organic chemicals will be determined largely by their sorption interactions with soils or sediments. The organic matter content of natural sorbents is shown to be an important factor in determining their sorption properties. The sorption and desorption of phenol, 2-chlorophenol, and 2,4-dichlorophenol by a fine and coarse sediment fraction were measured in a continuous flow stirred cell. The sorption of up t 0.3 mmol/g of sorbent was not due solely to hy drophobic interactions. Desorption was slowe than sorption, and in some cases up to 90% of th sorbate was irreversibly held. The extensive hys teresis between sorption and desorption shows tha the desorption process is affected by the previou sorption. The penetrability and accessibility of or ganic matter associated with sediment are a majo influence in the sorption of compounds which tak part in extensive hydrogen-bond interactions (Murphy-IVI)

TURBIDITY INTERFERES WITH ACCURACY IN HEAVY METALS CONCENTRATIONS,
S. Stausberg.
Industrial Wastes, Vol. 29, No. 2, p 16-21, March, April, 1983. 2 Fig.

Descriptors: *Industrial wastes, *Heavy metals *Turbidity, Monitoring wells, Wells, Groundwat er, Groundwater pollution, Groundwater manage ment.

Heavy metal concentrations in groundwater at nine-acre non-ferrous metal plant in the northen part of the Atlantic Coastal Plain are largely at tenuated by interstitial claysand silts in the shallov aquifer underlying the plant. Most of the ground water originating from infiltration in the plant' grounds is discharged through the shallow aquife consisting of Pleistocene silty sands and gravel that are interspersed with silty clay lenses. T improve water quality samples taken in the area, a intensive well redevelopment program was under taken in the spring of 1980 to increase well diame ters by removing silt and clay from the aquife outside the gravel pack and stabilize the aquife sand, mainly at the interface. After redevelopment sample analysis indicated that the 1979 water sam ples had turbidity levels more than one order o magnitude higher. (Baker-IVI)

CATTLE GRAZING IMPACT ON SURFACE WATER QUALITY IN A COLORADO FRONT RANGE STREAM,
Rocky Mountain Forest and Range Experimen Station, Fort Collins, CO.
H. L. Gary, S. R. Johnson, and S. L. Ponce.
Journal of Soil and Water Conservation, p 124-128 March-April, 1983. 3 Fig, 3 Tab, 23 Ref.

Descriptors: *Surface water, *Water pollutio sources, *Grazing, *Cattle, *Colorado, Suspende solids, Ammonia, Bacteria, Eutrophicatior Manure, Water quality.

Cattle grazing in pastures bisected by a small pe rennial stream in central Colorado had only mino effects on water quality during two years of study Suspended solids and nitrate nitrogen did not in crease significantly. The ammonia nitrogen in creased significantly only once under moderat rates of grazing. Indicator bacteria densities in th stream water were significantly higher when a least 150 cattle were grazing. After removal o cattle or when 40 head of cattle were grazing bacterial counts dropped to levels similar to thos in an adjacent, ungrazed pasture. About 5% of th total manure produced by cattle contributed t pollution and/or enrichment of the stream (Murphy-IVI)

IMPACT OF LAND USE ON GROUND-WATER QUALITY IN SOUTHERN DELAWARE,
Delaware Univ., Newark. Dept. of Agricultural Engineering.
W. F. Ritter, and A. E. M. Chirnside.
Ground Water, Vol. 22, No. 1. p 38-47, January-February, 1984. 1 Fig, 10 Tab, 10 Ref.

Descriptors: *Land use, *Delaware, *Groundwater pollution, *Nitrates, *Water table wells, Poultry, Sussex County, Kent County, Animal wastes, Water pollution sources, Fertilizers, Septic tanks.

In Kent and Sussex counties, ground water is the only source of water. The water-table aquifer contains most of the groundwater reserves. In the coastal areas of Sussex County excessive levels of nitrate were found in the drinking water supplies from 210 wells sampled 12 times each. In noncoastal Sussex and Kent Counties, 272 wells were sampled once each season over a period of one year. Over 99 percent of the wells were in the watertable aquifer. In coastal Sussex County, 32% of the wells had average nitrate concentrations above the EPA drinking water standard of 10 mg/l N. In noncoastal Sussex County and Kent County, 21% and 8% of the wells respectively, had nitrate concentrations above 10 mg/l. The highest nitrate concentrations occurred in areas with intensive broiler production or intensive crop production with excessively-drained soils. Nitrate concentrations in forest areas were <1.5 mg/l. Poultry manure, septic tanks and fertilizers all contributed to the high nitrate concentrations. Poultry manure was one of the major causes of nitrate contamination in four out of the five top prioritized groundwater problem areas. Bacteria contamination was low in all sampling areas. Lead, cadmium and chromium were far below drinking water standards in all but a few wells. (Murphy-IVI)

HYDROLOGIC DELINEATION OF NONPOINT SOURCE CONTRIBUTING AREAS,
Science and Education Administration, University Park, PA. Northeast Watershed Research Center.
W. J. Gburek.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1035-1048, October, 1983. 7 Fig, 19 Ref.

Descriptors: *Hydrologic delineation, *Nonpoint pollution sources, Land use, Regulations, Rainfall-runoff relationships, Surface flow, Surface runoff, Hydrodynamics, Simulation analysis.

Land-use regulations for reduction of nonpoint source pollution from surface-applied contaminants do not usually consider the differing hydrologic responses of land areas based on soil type, slope, proximity to the stream, and expected rainfall. To help overcome this shortcoming, one can define the area of a watershed contributing surface runoff directly to the stream as the result of any rain. Using design rainfalls and initial watershed soil moisture as input, a map can be drawn showing the return period with which any part of the watershed contributes surface runoff, and thereby potential nonpoint source pollution, to the stream. A small agricultural watershed in east-central Pennsylvania defines the restricted-use areas on a watershed and eliminates the subjective nature of commonly proposed land-use regulations by accounting for both the watershed characteristics and the probabilities controlling the generation of surface runoff and its direct affects on the stream. GRAVITY WASTEWATER COLLECTION SYSTEMS OPTIMIZATION,
Indian Inst. of Tech., Bombay.
A. Gupta, S. L. Mehndiratta, and P. Khanna.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1195-1209, October, 1983. 7 Fig, 6 Tab, 22 Ref.

Descriptors: *Gravity flow, *Wastewater collection, *Systems analysis, *Optimum development plans, Algorithms, Computer models, Dynamic programming, Computers, Cost allocation, Cost analysis, Drainage systems, Drainage patterns, Wastewater management, Water quality control.

It is the obligation of wastewater engineers to use optimal design methodology in present times of high cost of wastewater collection system and limited financial resources to meet the commitment of the Government with respect to urban sanitation. A computer algorithm selects the optimal depth-diameter combinations for all links of a complete gravity wastewater collection system using dynamic programming. The algorithm incorporates two subprocesses P1 and P2. The subprocesses P1 generates all feasible designs of inflowing lines at a junction manhole whereas P2 uses these feasible designs to provide the upstream invert level of the outflow line, simultaneously solving the matching problem encountered at each junction manhole. The problem of dimensionality is minimized by exploiting the characteristic features of wastewater collection system. The optimal design for a 10.7 km long collection system at Indian Institute of Technology, Bombay with 52 lines, 245 links, 224 ordinary manholes and 21 junction manholes is compared with conventional design to bring out that the algorithm requires a small computer memory, a small execution time and leads to optimal solution of a complete gravity wastewater collection system. CALIBRATION OF NPS MODEL LOADING FACTORS,
Camp, Dresser and McKee, Inc., Annandale, VA.
J. P. Hartigan, T. F. Quasebarth, and E. Southerland.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1259-1272, December, 1983. 8 Fig, 5 Tab, 8 Ref.

Descriptors: *Calibrations, *Nonpoint pollution submodel, *Load distribution, Computer models, Nonpoint pollution sources, Pollution load, Land use, Simulation analysis.

The use of continuous simulation models can facilitate the development of loading factors and loading projections because they deterministically account for the impact of hydrometeorologic and physiographic differences on nonpoint pollution loadings. NPS continuous simulation model calibrated to 11 single-land use watersheds in Chesapeake Bay drainage area derived nonpoint pollution loading factors (total N and total P) for rural, agricultural, and urban land use categories. Flow, rainfall, and nonpoint pollution monitoring records for each test watershed cover approximately 1-1.5 years. Parameter adjustments for calibration of both the hydrologic and nonpoint pollution submodels relied upon NPS model executions with continuous 15-minute rainfall record covering the entire monitoring period. Parametric and nonparametric statistics were used to assess goodness-of-fit for nonpoint pollution loading calibration. In light of the higher power than normal statistics for datasets characterized by small sample sizes and skewed distributions, nonparametric statistics are recommended for goodness-of-fit assessments for nonpoint pollution loading models. Each test watershed site of calibrated NPS loading factors for total N and total P covered forest, pasture, high tillage cropland, low tillage cropland and urban residential land use categories. Simulated annual unit area loads for each land use are compared for years of normal and above-average rainfall. (Murphy-IVI)

DIFFUSIVITY-BASED FLUX OF PHOSPHORUS IN ONONDAGA LAKE,
Upstate Freshwater Inst., Syracuse, NY.
M. C. Wodka, S. W. Effler, C. T. Driscoll, S. D. Field, and S. P. Devan.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1403-1415, December, 1983. 5 Fig, 1 Tab, 28 Ref.

Descriptors: *Diffusion coefficient, *Fluctuations, *Phosphorus, *Onondaga Lake, Thermal stratification, Organic matter, Organic load, Isotherms, Water pollution effects.

High concentrations of critical phytoplankton nutrients commonly develop in the hypolimnia of productive lakes as a result of mineralization processes on organic matter depositing from the upper productive waters. The upward transport of phosphorus through the lower portion of the metalimnion of hypereutrophic Onondaga Lake, is mediated by vertical diffusivity. This upward flux is simulated by Fickian diffusion, which incorporates estimates of the vertical diffusivity coefficient for heat and measurements of the vertical phosphorus gradient. The turbulent component of vertical diffusivity demonstrated a strong seasonality during the stratification period, varying from 0.060 sq cm/sec in early summer to 0.002 sq cm/sec during the maximum stability period of late summer. The total dissolved phosphorus gradient increased during stratification to a maximum of 0.14 mg/L/m in late August and early September. The internal loading of phosphorus to the epilimnion from diffusivity-based transport during the study is approximately 21% and 18%, respectively, of the external loading of dissolved and total phosphorus. The elimination of the present industrial ionic loading to the lake could result in increased internal loading of phosphorus through vertical transport by as much as a factor of 7. (Murphy-IVI)

ACCUMULATION OF PCBS, MERCURY AND CADMIUM BY NEREIS VIRENS, MERCENARIA MERCENARIA AND PALAEMONETES PUGIO FROM CONTAMINATED HARBOR SEDIMENTS,
Environmental Research Lab., Gulf Breeze, FL.
N. I. Rubinstein, E. Lores, and N. R. Gregory.
Aquatic Toxicology, Vol. 3, No. 3, p 249-260, April, 1983. 4 Fig, 1 Tab, 23 Ref.

Descriptors: *Bioaccumulation, *Polychlorinated biphenyls, *Mercury, *Cadmium, *Sandworms, *Clams, *Shrimp, *Contamination, *Sediments, Dredging, Ocean dumping, Fate of pollutants, Bioindicators, Coastal zone management, Water quality management, Water pollution control.

To ensure that disposal operations are conducted with a minimal degree of risk, dredged material destined for ocean disposal must be evaluated on the basis of criteria established by the Environmental Protection Agency. Disposal evaluations currently utilize bioassays to detemine the biological availability of contaminants associated with dredged sediments. In a 100-day period in New York Harbor sandworms (Nereis virens), hard clams (Mercenaria mercenaria) and grass shrimp (Palaemonetes pugio) had an accumulation of polychlorinated biphenyls (PCBs), mercury, and cadmium. Of the three contaminants monitored, only PCBs were found to bioaccumulate above background (control) concentrations. Small increases in PCB body burden were in M. mercenaria and P. pugio, whereas higher concentrations were in N. virens. Uptake was affected by the organic content of the sediment. Bioaccumulation factors (concentration in tissue/concentration in sediment) for N. virens ranged from 1.59 in a low organic sediment to 0.15 in a high organic sediment. Sediment concentration alone does not reflect bioavailability and toxicity tests (bioassays) and field monitoring remain the most direct method for estimating bioaccumulation potential of sediment-bound contaminants. (Murphy-IVI)

PCB DYNAMICS IN HUDSON RIVER STRIPED BASS, II. ACCUMULATION FROM DIETARY SOURCES,
New York Univ. Medical Center, NY. Inst. of Environmental Medicine.
J. C. Pizza, and J. M. O'Connor.
Aquatic Toxicology, Vol. 3, No. 4, p 313-327, May, 1983. 5 Fig, 3 Tab, 32 Ref. NIEHS grant ES 00260.

Descriptors: *Polychlorinated biphenyls, *Fish, *Fate of pollutants, Hudson River, Bass, Pharmacokinetics, Organic compounds, Industrial wastes, Water pollution effects, Bioaccumulation.

The entire food web of the Hudson esturary is contaminated with PCB. It may be assumed, therefore that PCB accumulation by fish is due partly to direct uptake from water and partly due to accumulation from the diet. Young-of-year striped bass given known doses of (14)C-labeled Aroclor 1254 in natural food by gavage had polychlorinated biphenyl accumulation from the gut. Elimination from the whole body were determined empirically for single-dose and multiple-dose studies. The data have been applied to models describing adsorption site kinetics and fluctuations in whole body burden at steady state. Those variables critical to the calculation and understanding of bioaccumulation factors, namely growth, metabolic rate, and dose, are discussed in the context of the kinetic model results. COPROSTANOL DISTRIBUTION FROM SEWAGE DISCHARGE INTO SARASOTA BAY, FLORIDA,
Mote Marine Lab., Sarasota, FL.
R. H. Pierce, and R. C. Brown.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 1, p 75-79, January, 1984. 1 Fig, 15 Ref.

Descriptors: *Pollutant identification, *Wastewater treatment, Coprostanol, Feces, Sarasota Bay, Florida, Wastewater, Sewage bacteria, Fate of pollutants.

Distribution of the fecal sterol, coprostanol, in sediment from 41 sites throughout Sarasota Bay, Florida, determined the impact of sewage effluent discharged from the City of Sarasota's wastewater treatment plant. Coprostanol was used as the indicator to estimate the extent to which sewage-derived particulate matter has been distributed within Sarasota Bay sediment. To estimate the area of the bay impacted by the sewage effluent, it is assumed that a coprostanol concentration of more than 10 ng/g dry-weight sediment indicates the presence of sewage derived material. The area affected by corprostanol was about 36 sq km. To observe corprostanol input from non-sewage effluent sources, sediment was taken from the mouth of two tributary draining areas of land-use similar to Whitaker Bayou. These sites were Bowless Creek and Hudson Bayou. The relatively high coprostanol concentration found in Hudson Bayou may be related to sewage due to periodic overflow that has been documented from sewer lines in that area. (Baker-IVI)

CARBON DIOXIDE EMISSION AND CARBON ACCUMULATION IN COASTAL WETLANDS,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
C. J. Smith, R. D. DeLaune, and W. H. Patrick, Jr.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 1, p 21-29, July, 1983. 4 Fig, 3 Tab, 28 Ref.

Descriptors: *Carbon dioxide, *Emission, *Accumulation, *Coastal marshes, Fluctuations, Carbon cycle, Marshes, Detritus, Accretion, Organic carbon, Chemical properties, Barataria basin, Louisiana.

Carbon dioxide production and subsequent release to the atmosphere are important processes in the overall carbon budget in coastal wetlands. Direct measurements of CO2 fluxes from salt, brackish and freshwater marshes in Barataria Basin, Louisiana, had accumulations of 418, 180 and 618 g C/sq m respectively. Water bodies adjacent to the marsh evolved 103, 54 and 242 g CO2-C/sq m/yr to the atmosphere from saline, brackish and freshwater lakes, respectively. The marshes are a major carbon sink because of the carbon content of the sediment, vertical accretion rates and the bulk density of the sediment. Net carbon accumulation was essentially the same in all three marshes; 183, 296 and 224 g C/sq m/yr from the salt, brackish and fresh marsh, respectively. there is a limited net export of carbon from these coastal marshes. A large percentage of fixed carbon remained on the marsh, being immobolized in accretionary processes or lost to the atmosphere as CO2. (Murphy-IVI)

TRACE METALS IN THE GOTA RIVER ESTUARY,
Chalmers Univ. of Technology, Goeteborg (Sweden). Dept. of Analytical and Marine Chemistry.
L. G. Danielsson, B. Magnusson, S. Westerlund, and K. Zhang.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 1, p 73-85, July, 1983. 9 Fig, 1 Tab, 17 Ref.

Descriptors: *Trace metals, *Gota River, *Estuaries, Sediment transport, Sediment distribution, Particulate matter, Path of pollutants, Mixing, Cadmium, Copper, Iron, Nickel, Lead, Zinc, Sweden.

The Gota River and its estuary are relatively unpolluted compared to other similar areas. The estuary represents a salt wedge type estuary and is situated in a densely populated region of Sweden. The concentrations of trace metals Cd, Cu, Fe, Ni, Pb and Zn are in the range regarded as background levels for freshwater. Metal fractions include acid-leachable, dissolved, labile and particulate. When water with low suspended matter concentration reaches the estuary conservative behavior of the trace metals generally occurs, the main exceptions being dissolved iron and lead. These are the only elements that partly exist in colloidal form in the Gota River estuary. The processes of removal of dissolved trace metals is not very effective. The conservative behavior of several trace metals may be due to the low dissolved iron concentration. Although iron is partly removed the amount of new iron-rich particles formed in the estuary is too small to influence the dissolved concentration of the other trace metals, save lead. (Murphy-IVI)

QUALITY CHANGES IN BAGHDAD CANALS AND IRRIGATION,
Biological Research Center, Baghdad (Iraq). Dept. of Pollution Research.
M. F. Al-Shahwani, M. W. Ishaq, A. K. Al-Hindawi, S. A. Ali, and N. Muthafar.
Journal of Environmental Sciences and Health, Vol. A18, No. 6, p 773-785, 1983. 2 Fig, 2 Tab, 7 Ref.

Descriptors: *Baghdad, *Iraq, *Canals, *Water quality, Irrigation canals, Domestic wastes, Coliforms, Diatoms, Water pollution sources, Heavy metals, Saline water.

The change of physical, chemical and biological characteristics of Al-Jaysh and Al-Khair canals are due to continuous untreated discharge of domestic waste. Al-Jaysh contained higher turbidity and electrical conductivity than Al-Khair. Both parameters decreased from up to down stream. Fecal coliform and diatom amounts in both canals were about the same. Diatoms decreased from up to down stream and had a higher resistance than fecal coliform at Al-Khair. Al-Khair contained higher biological oxygen demand than Al-Jaysh. There was no sign of self purification for both canals. In general, heavy metals decreased from up to down stream. Sedimentation of these metals, rather than precipitation, was more important. In most of the agriculture area in Baghdad, a build up of salt due to excessive irrigation and the absence of drainage can amount to 12.7 t/ha/year from Al-Jaysh, and 11.5 t/ha/year from Al-Khair. (Murphy-IVI)

Schweizerische Zeitschrift fur Hydrologie, Vol 45, No. 1, p 233-245, October, 1983. 4 Fig, 4 Tab 27 Ref.

Descriptors: *Polychlorinated biphenyls, *DDT, *Sediments, *Lake Geneva, *Switzerland, Pesticides, Lake shores, Graphical analysis, Pollutant identification, Water pollution.

The concentrations of PCB, p,p'-DDT, p,p'DDD and p,p'-DDE from sediment samples from the shoreline of Lake Geneva were taken at 15 places at depths varying between 10 and 25 m. The PCB concentrations, expressed in dry weight of sediment, varied from 20 micrograms/kg in the region of Les Grangettes to 420-430 micrograms/kg in the Lausanne area. These concentrations are high and could produce a long-term contamination of the Lake Geneva ecosystem. The PCB identified consisted mainly of moderately and highly chlorinated biphenyls. The concentration of p,p'-DDT, p,p'-DDD and p,p'-DDE, expressed in dry weight of sediment, varied from 0.5 micrograms/kg in the region of Les Grangettes to 49 micrograms/kg in the Cully area. These types of pollution (especially DDT) are decreasing in the lake ecosystem. (Murphy-IVI)

EFFECT OF SOLUBLE SPECIES RELEASED FROM SOIL SOURCES ON THE COMPOSITION OF SOIL AND DRAINAGE SOLUTIONS,
Agricultural Research Organization, Bet-Dagan (Israel).
R. Levy, I. Shainberg, R. Mazouz, and H. Eisenberg.
Soil Science Society of America Journal, Vol. 47, No. 6, p 1092-1096, November/December, 1983. 2 Fig, 6 Tab, 14 Ref.

Descriptors: *Irrigation water, *Minerals, *Leachates, *Soil chemistry, Chlorides, Bicarbonates, Sodium, Soil solution, Calcium, Magnesium, Water pollution sources, Dissolution.

Two soils differing in the amounts of calcium and magnesium released during dissolution of soil minerals, cation exchange capacity (CEC), lime content, and water-holding capacity were irrigated under the same conditions with four synthetic waters. Two of the waters contained only chloride and the other two contained both chloride and bicarbonate anions. Sodium adsorption ratios of the two chloride and two bicarbonate waters were either 10 or 20. Following every 10 wetting and drying cycles the two soils were leached with about 10% excess water. Five such leachates were collected and analyzed. Soil analysis was performed after 20 and 40 irrigation cycles. A significant difference was found between the chemical composition of the drainage and soil solutions of the two soils. To evaluate this diversity, the law of mass conservation was used to calculate the amounts of calcium and magnesium released by dissolution in the absence and presence of carbonate precipitation. Two assumptions were used in these calculations: (i) during irrigation with the chloride waters no precipitation of carbonates occurred, and (ii) during irrigation with the bicarbonate waters no dissolution took place. These assumptions proved valid only for the soil that released small amounts of salt by dissolution. The two soils released almost equal amounts of calcium and magnesium from exchange sites, although there was a significant difference in CEC. It was concluded that the primary source that induced the differences in chemical composition of the drainage and soil solutions was the amount of calcium and magnesium released by mineral dissolution. INVESTIGATIONS ON HEAVY METAL SPECIATION IN NATURAL WATERS BY VOLTAMMETRIC PROCEDURES,
Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. fuer Angewandte Physikalische Chemie.
H. W. Nurnberg.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 316, No. 6, p 557-565, November, 1983. 6 Fig, 1 Tab, 56 Ref.

Descriptors: *Heavy metals, *Chemical speciation, *Voltammetry, Natural waters, Water pollution, Complexation, Metalloids.

The speciation of dissolved heavy metals is of great significance for their interactions with suspended matter and sediments and their uptake by aquatic organisms. Substance-specificity combined with extraordinary detection sensitivity and inherently high accuracy make suitable advanced modes of polarography and voltammetry one of the most powerful and convenient methodological approaches for speciation studies of heavy metals of ecotoxic significance in all types of natural water. Not all heavy metals are accessible to voltammetry, but voltammetry is one of the most powerful methods for studies of heavy metals and metalloids of predominant ecotoxic significance and impact. Diagnostic information on the speciation and distribution emerge in the course of the analytical procedure for the determination of the overall heavy metal concentrations in the dissolved state and the suspended matter phase of natural waters. The complexation capacity is conveniently determined by a voltammetric titration. A very important and successful application area of voltammetry in heavy metal speciation research is specific studies with defined heavy metal complex species on the general physiochemical parameters governing the speciation of the heavy metal in various natural water types. Dissolved heavy metals exist in natural waters in three categories of species: labile complexes, predominantly formed with inorganic ligands; free hydrated cations; and stable non-labile complexes, predominantly of natural origin but in certain pollution situations also from anthropogenic sources. Fresenius Zeitschrift fur Analytische Chemie, Vol. 316, No. 6, p 582-588, November, 1983. 3 Fig, 9 Tab, 31 Ref.

Descriptors: *Humic substances, *Metals, *Chemical binding, Copper, Dissolved organic carbon, Complexation, Heavy metals, Iron, Hydroxamic acid, Photochemical decomposition, Ligands.

Humic substances (HUS) are present in all aquatic systems. Their analytical identification and quantification suffers from a lack of knowledge of the general structure. Therefore sum- and group-parameters, such as dissolved organic carbon (DOC) or carboxylic groups, are of great importance for the characterization of humic substances and their reactivity. Humic/metal interactions can be determined under defined reaction conditions. Model experiments are helpful to confirm these results. Complexation capacities (CC) reflect the maximum of metal binding ability for the unit of HUS. The CC in respect to Cu(II) was determined by the titration of the initial amount of Cu(II) (10 micro mol/l) with a HUS-solution of known DOC at a pH-value of 6.8. Differential pulse polarography with a dropping mercury electrode was used for detection. The results (2 to 7 micro mol per mg DOC) suggest complex formation by oxygen containing functional groups in addition to nitrogen containing ones. Iron, strongly bound to HUS even at pH 2.2, shows some similarities to Fe(III) in hydroxamic acid compounds. Coordination of Hg(II) onto thio-groups of the humics can be confirmed by means of photochemical decomposition reactions using model ligands and natural samples. CCs for isolated humics suggest that in most natural aquatic systems there is an excess of organic ligand functions compared with the dissolved heavy metals. CCs, however, should only be discussed in close connection with the determination method applied and the reference metal concerned. (Author's abstract)

U. Forstner.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 316, No. 6, p 604-611, November, 1983. 7 Fig, 5 Tab, 70 Ref.

Descriptors: *Heavy metals, *Chemical binding, *Sediments, *Sludge, *Bioavailability, Extraction, Sorption, Mobilization, Iron, Manganese, Organic matter, Chemical speciation, Aquatic environment.

Only part of the metals present in sediments or sludges are involved in short-term geochemical processes and/or are bioavailable. Hydrous Fe- and Mn-oxides as well as organic matter, partly as coatings or films on detrital grains, are important substrates for the interactions with dissolved metal species in aquatic systems. For the differentiation of the relative bonding strength of metals on various solid phases and for the estimation of their potential reactivity under variable environmental conditions sequential extraction procedures were used. While these determinations seem to pose basically operational problems, the correlation of the data from solid speciation with the processors and extent of the biological uptake is still unsatisfactory. This is mainly due to the competition between sorption sites on solid matter and biological processes for dissolved metals. Investigations on pore waters could give useful indications on the availability of metals for organisms. (Author's abstract)

EFFECTS OF SURFACE MINING ON AQUATIC RESOURCES IN NORTH AMERICA,
L. B. Starnes.
Fisheries, Vol. 8, No. 6, p 2-4, November-December, 1983. 5 Ref.

Descriptors: *Surface mining, *Environmental effects, *Hydrologic systems, Aquatic habitats, Land reclamation, Planning, Resources management, Wetlands.

Mining may result in long-term disruption of terrestrial and aquatic habitats, and hydrologic systems. The magnitude of surface mining impacts on aquatic life depends on the mining technology employed, extent of the disturbance, chemical and physical composition of the mineral, surface and subsurface hydrologic patterns, and methods of reclamation. Research and monitoring needs associated with specific minerals or mining technologies include methodology, development, wetland reclamation strategies, stream strategies and methods of predicting eventual toxicity. This encompasses a need for collaborative data bases and regionalized computer models to provide alternative strategies and a priori answers concerning when multiple mines will create unacceptable impacts. LAGRANGIAN METEOROLOGY AND MEASUREMENTS OF ACIDIC PRECIPITATION AT WASHINGTON, D.C.,
National Oceanic and Atmospheric Administration, Rockville, MD. Air Resources Labs.
R. R. Draxler.
Atmospheric Environment, Vol. 17 No. 12, p 2525-2531, 1983. 6 Fig, 2 Tab, 17 Ref.

Descriptors: *Lagrangian meteorology, *Acid rain, *Washington, *District of Columbia, Hydrogen ion concentration, Temperature, Rainfall, Humidity, Model studies, Air pollution, Fate of pollution, Sulfur compounds, Nitrogen compounds, Chemistry of precipitation.

Various studies have attempted to link episodes of acidic rainfall with particular source regions without considering the intervening chemical and physical processes of Eulerian and Lagrangian models using an emmission inventory coupled with rainfall chemistry-modules to account for sulfate deposition over the region of interest. In the latter, more complex models, it is presumed that the rainwater pH is related to the SO4/NO3 deposition. Lagrangian averages of temperature, rainfall, relative humidity and normalized concentration from a multiple source trajectory model compares with measurements of pH from daily rainwater samples collected around the Washington, DC area during 1975. A linear regression procedure in which pH depends upon the previous four parameters determines the likely source regions during the year. The most consistent acidic rainfall occurred during an extended period from May to June when the flow was from the north. Some investigators have suggested that the rainfall at the receptor is a better predictor of pH than the Lagrangian precipitation. Tests of the four independent variables indicated that the most important predictor of pH during the summer was average rainfall along the trajectory (slope > 0). The variability of the meteorological conditions along the pollutant trajectories was able to explain half of the variance of pH, suggesting that at least during summer complex chemical models may not be necessary to simulate acidic precipitation. During the winter, the results were more ambiguous, with the normalized concentration appearing to be the best predictor of pH. (Murphy-IVI)

MICROBIAL HETEROTROPHIC UTILIZATION OF DISSOLVED ORGANIC MATTER IN A PIEDMONT STREAM,
Academy of Natural Sciences of Philadelphia, Avondale, PA. Stroud Water Research Center.
L. A. Kaplan, and T. L. Blott.
Freshwater Biology, Vol. 13, No. 4, p 363-377, August, 1983. 6 Fig, 8 Tab, 35 Ref. NSF grant DES 77-12902.

Descriptors: *Microbial utilization, *Dissolved organic matter, *Piedmont, *Streams, Streambeds, Sediments, Bacteria, Dissolved organic carbon, Biosynthesis, Stormflow, White Clay Creek, Pennsylvania, Leachate.

Dissolved organic matter (DOM) contributes significantly to the total organic matter budgets of streams and rivers, often dominating the pool of organic matter in transport. The microbial heterotrophic utilization of (DOM) was determined experimentally in microcosms using stream water and stream-bed sediments from a third order reach of White Clay Creek (Pennsylvania, U.S.A.). Sources of DOM for the experiments included White Clay Creek water at baseflow and stormflow and cold water extracts of jewel weed (Impa-

tiens capensis L.) and spicebush (Lindea benzoin (L.) Blume). The heterotrophic activity of the sediments was measured as uptake of the following: dissolved organic carbon (DOC), molecular weight fractions within the DOC pool, carbohydrates, amino acids and peptides, phenolics, and dissolved oxygen (DO), all in the overlying water. Concentrations of adenosine triphosphate (ATP), and direct microscopic counts of bacteria were used to estimate bacterial biomass in the surface sediments. The microcosm experiments showed that specific DOC molecular size classes and DOM functional groups were selectively removed from solution, exposure to one DOM source affected responses to a different DOM source and certain DOM sources were more readily utilized than others. Continued exposure to a DOM source increased microbial heterotrophic activity (a condition which persisted even after removal of the DOM source for several days). Rates of biotic DOC uptake ranged from 3.6 to 242.8 mg C/sq m/h. 8. Indirect estimates of biosynthesis calculated from DOC and DO data ranged from 1.6 at baseflow and 2.6-61.2 at stormflow to as high as 192.6 mg C/sq m/h when the community was repeatedly exposed to enriched DOM sources. The mean generation tin.es of bacteria in sediments, determined from direct microscopy data, ranged from 12.5 to 46.2 h at 15 degrees C. (Murphy-IVI)

RELATIONSHIPS BETWEEN CHLORIDE AND MAJOR CATIONS IN PRECIPITATION AND STREAMWATERS IN THE WINDERMERE CATCHMENT (ENGLISH LAKE DISTRICT),
Freshwater Biological Association, Windermere (England).
D. W. Sutcliffe, and T. R. Carrick.
Freshwater Biology, Vol. 13, No. 5, p 415-441, October, 1983. 16 Fig, 11 Tab, 79 Ref.

Descriptors: *Chloride, *Cations, *Precipitation, *Windermere catchment, *Streams, Hydrogen ion concentration, Sodium, Potasium, Calcium, Magnesium, Water pollution sources, Fate of pollutants, Pollution load, Ions, Chemistry of precipitation, England.

Before starting to manipulate the concentrations of solutes we need to know their natural range and identify major sources of variation in local streams. Variation in stream water concentrations can be directly related to input by precipitation on the Windermere catchment. The distribution of invertebrates in hill-streams is related to the chemical composition of streamwater, especially with regard to the concentrations of H(+). Low concentrations of other major ions, Na(+), K(+), Cl(-), might also be important limiting elements for some taxa. Relative contributions of inputs were from precipitation, rocks (Borrowdale Volcanics) and soils, sewage, and deicing salt used on highways. In bulk precipitation, ratios of Na(+)/Cl(-) (as microequiv/l) ranged from 0.41 to 1.83 over a 2-year period. The overall volume-weighted mean ratio was 0.86, as in seawater, but 2.4% (1975) and 5.7% (1976) of Cl(-) was non-marine in origin, being balanced by H(+) (in winter), K(+) and Ca(2+) (in summer). In moorland headwater streams, Cl(-) is largely derived from precipitation; there is a pronounced annual cycle of midwinter high and midsummer low concentrations unrelated to stream discharge. Na(+) and K(+) display similar cycles but Na(+), Ca(2+) and Mg(2+) (and pH) are discharge-related due to leaching from rocks and soils: 10-20% Na(+), 15-17% Mg(2+) and 65-75% Ca(2+) are so-derived whereas K(+) comes from precipitation. Na(+)/Cl(-) ratios in streams on Borrowdale Volcanics alter seasonally, with midsummer values > 1.0. Lower values occur in streams on Silurian Slates where some Cl(-) is apparently derived from rocks. Seasonal changes in streamwater concentrations of Cl(-), Na(+) and K(+) are exponentially related to time. Instantaneous rates of change (%/day) are compared in relation to position in the catchment and inputs from anthropogenic sources. Deicing salt has raised (10-100-fold) the concentrations of Na(+) and Cl(-) in streams on mountain passes; the effects persist throughout the year. (Murphy-IVI)

MODEL OF PCB IN THE LAKE MICHIGAN LAKE TROUT FOOD CHAIN,
Manhattan Coll., Bronx, NY. Environmental Engineering and Science Program.
R. V. Thomann, and J. P. Connolly.
Environmental Science and Technology, Vol. 18, No. 2, p 65-71, February, 1984. 7 Fig, 1 Tab, 35 Ref. CR 805916010.

Descriptors: *Fish, *Water pollution effects, Polychlorinated biphenyls, Organic compounds, Food chains, Model studies.

The significance of the food chain route, i.e., the degree to which a chemical such as PCBs may be accumulated in an organism by predation, needs to be placed in a mechanistic predictive framework to be able to calculate expected levels under field conditions. An age-dependent food chain model that considers species bioenergetics and toxicant exposure through water and food is developed. The model is successfully calibrated to 1971 PCB concentrations of Lake Michigan alewife and lake trout by using a dissolved PCB concentration in the water of 5-10 nanograms/liter. The model indicates that for the top predator lake trout, PCB exposure through the food chain can account for greater than 99% of the observed concentration. An octanol-water partitioning calculation and lake trout lipid concentrations failed to reproduce the observed data by a factor of about It is estimated that a criterion specifying that PCB concentrations of all ages of lake trout be at or below 5 micrograms/g in the edible portion would requrie that dissolved PCB concentrations be reduced to somewhere between 0.5 and 2.5 ng/liter. The projections of the behavior of the lake trout food chain to reduced water concentrations indicate that following reduction in water column PCB concentrations, a period of about 5 years is needed to reduce whole body PCB concentration in upper age class lake trout. Younger age classes can generally be exposed to higher water PCB concentrations than older age classes without exceeding the objective of 5 micrograms/g. If water quality projections indicate a lower bound in the achievable PCB water concentrations, a size-dependent fish consumption guideline can be developed. (Baker-IVI)

SOURCES AND TRANSPORT OF HYDROCARBONS IN THE GREEN-DUWAMISH RIVER, WASHINGTON,
National Oceanic and Atmospheric Administration, Seattle, WA. Pacific Marine Environmental Lab.
S. E. Hamilton, T. S. Bates, and J. D. Cline.
Environmental Science and Technology, Vol. 18, No. 2, p 72-79, February, 1984. 3 Fig, 2 Tab, 33 Ref.

Descriptors: *Hydrocarbons, *Water pollution sources, *Rivers, Green-Duwamish River, Washington, Estuarine environments, Sewage discharge, Wastewater treatment facilities, Wastewater.

Hydrocarbon compounds are introduced into nearshore waters by wastewater discharge, surface runoff, casual spillage, and atmospheric deposition. Since petroleum hydrocarbons are largely hydrophobic and lipid soluble, a major transport mechanism of these compounds in riverine and estuarine systems is via their association with suspended particulates. Five major sources of hydrocarbons have been defined along the Green-Duwamish River. The plant wax hydrocarbons are the predominant compounds in the upper river. Pentadecane, heptadecane, and several C-17 monoenes are produced by algae in the river. Highway runoff along the river contributes the suite of C14-C20 alkanes. The terpenoids and high concentrations of pristane appear to be erosional in origin and are periodically transported down the river under high flow conditions. A secondary waste treatment plant is a major point source of hydrocarbons to the river. The differences in hydrocarbon concentrations between test stations can be largely attributed to simple dilution. A disparity was noted when attempts were made to quantitatively account for the input from the Renton Sewage Treatment Plant. This disparity may be due to the flocculation and sedimentation of organic matter during mixing of the effluent and river water with subsequent near-bottom transport of this material during periods of high river flow. (Baker-IVI)

SEWAGE SLUDGE COAGULATION AND SETTLING IN SEAWATER,
California Univ., Berkeley. Div. of Sanitary, Environmental, Coastal, and Hydraulic Engineering.
J. R. Hunt, and J. D. Pandya.
Environmental Science and Technology, Vol. 18, No. 2, p 119-121, February, 1984. 1 Fig, 2 Tab, 9 Ref.

Descriptors: *Sludge coagulation, *Settling, *Seawater, *Particulates, Model studies, Coagulation, Mathematical models, Sludge disposal, Fate of pollutants.

The removal of sewage sludge particles from seawater is controlled by particle coagulation and the settling of aggregates as they are formed. Anaerobically digested sewage sludge coagulation in artificial seawater at fluid shear rates of 0, 0.25, 0.5, 1, 2, 4, and 8/s with a rotating cylinder apparatus had a sludge removal rate with a second order in sludge concentration and was dependent on the fluid shear rate. The settling velocity of aggregates produced at a given shear rate was constant. Limited experience to date suggests that particle coagulation rate and aggregate settling velocity are very dependent on fluid and particle properties. For this reason, specific data must be obtained for each waste under consideration. (Murphy-IVI)

AFFINITY OF HYDROPHOBIC POLLUTANTS FOR NATURAL ESTUARINE COLLOIDS IN AQUATIC ENVIRONMENTS,
Maryland Univ., Solomons. Chesapeake Biological Lab.
R. D. Wijayaratne, and J. C. Means.
Environmental Science and Technology, Vol. 18, No. 2, p 121-123, February, 1984. 1 Fig, 12 Ref.

Descriptors: *Herbicides, *Estuarine environment, Aquatic habitats, Water pollution effects, Chemical reactions, Colloids, Chromatography, Oxidation.

Gel chromatographic techniques were used to study the interaction of natural estuarine colloids with a model herbicide, (14)C labeled atrazine. Dissolved organic carbon binds atrazine and holds the resulting aggregate of molecules in stable colloidal suspension. Hydrophobic compounds held in such a manner show behavior characteristic of the natural organic matter rather than the behavior they would normally exhibit in solution. Oxidation of the compound-colloid complex by hydrogen peroxide or hypochlorite resulted in the partial destruction of the complex and release of bound herbicide. The average molecular weight of the estuarine polymer was estimated to be 10,000. The molecular weight is decreased with oxidation. Recoveries of radiolabeled atrazine from the gel chromatograpy studies in distilled water, estuarine colloids, and colloids treated with NaOCl and H2O were 80%, 90%, 84%, and 82%, respectively. Depending on their stability in the colloidal state hydrophobic contaminants can accumulate in concentrations far in excess of that expected for pure water. As surface-active organic matter is ubiquitous in natural waters, it seems reasonable to conclude that colloids may play a significant role in the distribution and concentration of trace quantities of hydrophobic contaminants in aquatic systems, which might otherwise be sequestered in sediments. (Baker-IVI)

PROCESSES CONTROLLING METAL ION ATTENUATION IN ACID MINE DRAINAGE STREAMS,
Commonwealth Scientific and Industrial Research Organization, Ryde (Australia). Physical Technology Unit.
B. M. Chapman, D. R. Jones, and R. F. Jung.

Geochimica et Cosmochimica Acta, Vol. 47, No. 11, p 1957-1973, November, 1983. 10 Fig, 5 Tab, 51 Ref.

Descriptors: *Acid mine drainage, *Metals, Heavy metals, Iron, Potassium, Lead, Copper, Zinc, Cadmiun, Sediments, Water analysis, Streams, Mine drainage, Water pollution source.

The study of the distribution of heavy metals at trace levels in uncontaminated natural streams provides information about the mechanisms which control the mobility of these elements at low concentrations. Detailed analyses were made of the sediments and waters in two acid mine drainage streams to understand the dominant processes controlling the transport and attenuation of heavy metals under conditions of chronic high-level pollutant input. One of the water courses has a thick hydrous iron oxide crust on its bed, where bioticaly mediated oxidation of ferrous iron resulted in precipitation of amorphous ferric hydroxide, along with substantial quantities of adsorbed silica, sulfate and Al and lesser quantities of As. Small amounts of K and Pb jarosites were also present in the sediments. Changes in pH and in the concentrations of Cu, Zn, and Cd appear to be mainly the result of dilution by seeps and tributaries. Although no sediment was recovered during collection of water samples from the second stream, saturation index calculations imply that precipitation was occurring. The basis for a potentially useful new tecnique, congruent element analysis, which enables the identification of conservative components in streams is presented. Comparison of logarithmic concentration versus distance plots delineates the point where chemical removal mechanisms become important for each element. (Baker-IVI)

TRANSFORMATIONS OF TETRACHLOROETHENE AND TRICHLOROETHENE IN MICROCOSMS AND GROUNDWATER,
Florida International Univ., Miami. Drinking Water Quality Research Center.
F. Parsons, P. R. Wood, and J. DeMarco.
Journal of the American Water Works Association, p 56-59, February, 1984. 3 Tab, 20 Ref.

Descriptors: *Transformation, *Tetrachloroethene, *Trichloroethene, *Microcosms, *Groundwater, Chemical reduction, Cis-1,2-dichloroethene, Trans-1,2-dichloroethene, Muck soils, Metal-finishing wastes, Incubation.

Cis- and trans-1,2-dichloroethene are found in well water at a site contaminated with trichloroethene from a leaking storage tank, although neither compound was used in the vicinity nor was present as an impurity in the trichloroethene in the storage tank. The use of tetrachloroethene and trichloroethene in dry cleaning and metal refinishing plants is widespread. Several chloroethene compounds that are found in southern Florida groundwater may have been formed from these solvents via microbial metabolism in the groundwater environment. Depletion of tetrachloroethene and appearance of cis- and trans-1,2-dichloroethene and chloroethene are present following incubation of tetrachloroethene in microcosms containing muck from the aquifer recharge basin. RADIOCHEMICAL TECHNIQUES APPLIED TO LABORATORY STUDIES OF WATER LEACHING OF HEAVY METALS FROM COAL FLY ASH,
Commission of the European Communities, Ispra (Italy). Radiochemistry and Nuclear Chemistry Div.
L. Goetz.
Water Science and Technology, Vol. 15, No. 11, p 25-47, 1983. 33 Fig, 4 Tab, 30 Ref.

Descriptors: *Radiochemical analysis, *Laboratory studies, *Leaching, *Heavy metals, *Coal, *Fly ash, Radioactivity techniques, Radioisotopes, Path of pollutants, Radioactive tracers, Isotopic tracers, Ions, Anions.

Assessment of the potential environmental impact of heavy metals (HM) mobilized by coal-fired power plants showed that water leaching of HM from pulverized fuel ash may for certain HM constitute an important pathway to the aquatic environment. Batch experiments simulate ash pond conditions, whereas column experiments represent water leaching from fly ash deposits. Using radioactive tracers and neutron activation of fly ash the fate of a single HM is easily followed even in very low concentrations. Employing radioisotopic tracers the distribution coefficients of simple ionic forms of As, Sb, Bi, Se, Te, Cr, Mo, W, Ni, and Cd in a coal fly ash/water system is determined as a function of pH. The adsorption and desorption behaviour of HM on coal fly is explained in part on the basis of the surface predominance and the aqueous chemistry of single ionic, mainly anionic, forms of the relative elements. Ion exchange and coprecipitation phenomena are also important processes. The nature and concentration of ions contained originally in the water used (distilled water, fly ash leachate and seawater) has a strong influence on the sorptive behavior of HM on coal ashes. MODEL OF ION EQUILIBRIUM IN AQUEOUS SOLUTIONS OF FLY ASH IN THE CONTEXT OF PREDICTION OF GROUND AND SURFACE WATER CONTAMINATION,
Instytut Ksztaltowania Srodowiska, Katowice (Poland). Environmental Pollution Abatement Centre.
M. J. Laczny, E. Krop, and M. Polak.
Water Science and Technology, Vol. 15, No. 11, p 239-246, 1983. 3 Fig, 7 Ref.

Descriptors: *Groundwater contamination, *Water pollution sources, Predicting, Fly ash, Model studies, Waste disposal, Computers, Algorithms.

Fly ashes contain readily and poorly soluble compounds which are leached due to water impact and infiltrate into the environment. Considerations of the impact of power waste landfill on the environment of groundwater and surface waters must not only include the quantitative composition of the aqueous solutions, which are in contact with fly ash, but also the kinetic relationships. Based on lab studies conducted on samples taken from the entire cross section of the disposal site, compounds were selected for which a qualitative-quantitative equilbrium model was calculated using electronic computers. The algorithm and equations used in the calculations are presented. The algorithm adopted for the calculation is universal for this type of ion equilbria. New equilibria can be easily introduced to the algorithm. The proposed model permits calculation of the resultant hydrochemical composition of water after mixing of the infiltration water from a landfill site with groundwater or surface waters, provided that the quantity of mixed waters is known. CHEMICAL PATHWAYS FROM STACK EMISSIONS TO SURFACE WATER,
Central Electricity Generating Board, Leatherhead (England). Central Electricity Research Labs.
A. S. Kallend.
Water Science and Technology, Vol. 15, No. 12, p 9-21, 1983. 4 Fig, 4 Tab, 26 Ref.

Descriptors: *Fate of pollutants, *Chemical reactions, Water pollution sources, Air pollution, Sulfur dioxide, Nitrogen oxides, Precipitation.

A complex chain of processes links the production of an anthropogenic atmospheric emission with its action in the aqueous environment. The importance of chemical transformations was examined in determining the impact of atmospheric emissions on the aquatic environment through precipitation. Special attention was given to chemical kinetics. Direct measurements as well as modelling studies based on kinetic parameters determined in the lab have resulted in a reasonable understanding of the gas phase chemical transformation of major primary pollutants. The relative abundance of sulfate and nitrate in precipitation does not, however, reflect the measured or predicted rate of production of nitric acid and sulfate aerosol in typical plumes in which gas phase chemistry predominates and suggests that, on the average at least, in-cloud chemical transformation along with direct precipitation scavenging accounts for a substantial part of the sulfate actually observed in precipitation at most sites. The chemical interaction of pollutants from the same source and from different sources is brought out most clearly when considering the effect of ambient air composition on the gas phase chemistry in plumes. However, oxidant availability during in-cloud oxidation of sulfur dioxide may be of even greater importance and may sometimes be the rate determining factor for sulfate production. The chemistry of the ambient air is also important at long range, particularly when it is of urban origin because this air itself contains many of the principal components that are also present in power plant plumes including sulfur dioxide, nitrogen oxides and their derivatives. To be both soundly based and cost-effective any future control strategy must likewise rely on a thorough understanding of the chemical pathways linking source and effect and on the resolution to further research of the areas of uncertainty. TRANSPORT OF AIRBORNE MERCURY EMITTED BY COAL BURNING INTO AQUATIC SYSTEMS,
Swedish Water and Air Pollution Research Lab., Goeteborg.
C. Brosset.
Water Science and Technology, Vol. 15, No. 12, p 59-66, 1983. 2 Fig, 6 Tab, 6 Ref.

Descriptors: *Mercury, *Path of pollutants, Coal, Water pollution sources, Air pollution, Precipitation, Coal combustion, Sweden.

Faced with the possibility of increased use of coal for energy production the Swedish government decided some years ago to sponsor a comprehensive investigation of all kinds of emissions connected with the combustion of coal and their eventual impact on the environment. One of the problems to be elucidated emphasized the consequences of the emission of mercury. Concentrations of water soluble and insoluble mercury compounds in air, precipitation and smoke from coal combustion have been measured. A concentration of total airborne mercury at remote places in southwestern Sweden was found to amount to 2-4 ng/cubic m. About 20% of it is probably anthropogenic. As the concentration in this fraction is proportional to the concentration of soot particles it is probably emitted in connection with coal burning. The total airborne mercury includes a water soluble fraction of 10-20%. A big part of this last fraction (about 80%) has stability properties indicating organic mercury compounds, possibly methyl mercury salts. The smoke from coal burning seems to have a similar composition. However, its water soluble concentration fraction may be near 70%. This fraction can be easily wet or dry deposited into aquatic systems. (Baker-IVI)

SULPHUR AND CHLORIDE DEPOSITION AND ECOSYSTEM TRANSPORT IN A STRONGLY ACIDIFIED LAKE WATERSHED,
Swedish Water and Air Pollution Research Lab., Goeteborg.
H. Hultberg, P. Grennfelt, and B. Olsson.
Water Science and Technology, Vol. 15, No. 12, p 81-104, 1983. 11 Fig, 10 Tab, 11 Ref.

Descriptors: *Sulfur, *Chloride, *Deposition, *Path of pollutants, *Acidic lakes, Watersheds, Acidic water, Chemical properties, Acid precipitation, Sweden, Ecosystems.

Field monitoring during a two-year period of concentrations in air, precipitation, streams and lakes, attempts to synthesize deposition and ecosystem transport of sulfur and chloride through a strongly acidified lake watershed on the Swedish west coast. The dry deposition estimate from concentra-

tion measurements and deposition estimate from concentration measurements and deposition velocities were in good agreement with monitored outflows. The estimated sulfur deposition to areas with coniferous forests was 25-31 kg/ha per year and to lake areas was 19 kg/ha per year. The marine part of the input is about 10%. The estimated retention of sulfur in the total watershed is 8-21%. (Murphy-IVI)

THE EFFECTS OF COAL COMBUSTION AND ACIDIFICATION ON THE CADMIUM EXPOSURE OF THE SWEDISH POPULATION,
Studsvik Energiteknik A.B., Nykoeping (Sweden).
L. Ramberg.
Water Science and Technology, Vol 15, No. 12, p 105-113, 1983. 3 Fig, 21 Ref.

Descriptors: *Cadmium, *Water pollution sources, Path of pollutants, Fertilizers, Industrial wastes, Sweden, Coal, Coal combustion, Burning, Air pollution.

A model has been developed and applied for release situations of cadmium which might occur in Southern and Middle Sweden. The model describes these areas of Sweden as composed of three compartments: forests, crop land, and lakes. The cadmium input to this simplified description of the biosphere comes from atmospheric precipitation, fertilizers and industrial releases to water as well as from coal combustion. The model is limited to an analysis of the large turnovers of cadmium on a long time scale in a sector of the biosphere and the mean health effects on the population as a whole. Cadmium balance and mobility in crop soils controls the cadmium flow to man. The atmospheric precipitation of cadmium is of dominant importance for controlling future exposures. The use of phosphorous fertilizers containing Cd may be harder to mitigate as alternatives are not well developed. (Baker-IVI)

HISTORICAL CHANGES IN ACID PRECIPITATION AND HEAVY METALS DEPOSITION ORIGINATING FROM FOSSIL FUEL COMBUSTION IN EASTERN NORTH AMERICA AS REVEALED BY LAKE SEDIMENT GEOCHEMISTRY,
Institut National de la Recherche Scientifique, Sainte-Foy (Quebec).
M. Ouellet, and H. G. Jones.
Water Science and Technology, Vol. 15, No. 12, p 115-130, 1983. 6 Fig, 2 Tab, 53 Ref.

Descriptors: *Acid rain, *Heavy metals, *Deposition, *Fossil fuel, *North America, *Lake sediments, *Geochemistry, Fuels, Tantare Lake, Laflamme Lake, Air pollution, Mercury, Lead, Zinc, Water pollution sources.

The sediments of remote 'undisturbed' lakes more accurately reflect any changes in atmospheric fallout from air masses originating from outside the watershed. The geochemical stratigraphic evolution of two soft water lakes (Tantare and Laflamme) reveal that the allochthonous inputs will dominate any changes in total inputs. The increase in Al in the sediments of Lake Tantare since about 1950 is attributed to the processes of surface water acidification of this watershed induced by acid precipitation. The analogous upper strata of the sediments from Lake Laflamme, a non-acidified lake, show no such increase in Al content. Pb, Zn and Hg levels in the sediments increased significantly from 1940 onwards. The subsequent reduction in the stratigraphic concentration of Zn since 1960 in both Lake Tantare and Lake Laflamme is, in all probability, the result of the important decrease of the total particulate emissions to the atmosphere from coal-fired plants. The same phenomenon may also explain Hg decrease during the same period. In contrast, Pb shows no such reduction in the more recent strata and the sustained increase of this element in the sediments is attributed to the progression in motor vehicle activity during the past twenty years. Further data from other isolated lakes suggest that the major sources of heavy metal deposition and acid precipitation in the Province of Quebec are the emissions from fossil fuel combustion (coal and/or motor fuel) originating in the heavily industrialized American Midwest and Great Lakes Regions. MINE DRAINAGE AND ROCK TYPE INFLUENCES ON EASTERN OHIO STREAM WATER QUALITY,
Geological Survey, Reston, VA.
D. R. Helsel.
Water Resources Bulletin, Vol. 19, No. 6, p 881-887, December, 1983. 2 Fig, 3 Tab, 15 Ref.

Descriptors: *Acid mine drainage, *Rock properties, *Ohio, *Streams, *Water pollution sources, Geochemistry, Land reclamation, Base flow, Land use, Groundwater pollution.

Stream water during fair weather (base flow) is largely ground water discharge, which has been in contact with minerals of the underlying aquifer. Base flow water quality should therefore reflect aquifer mineralogy as well as upstream land use. Three upstream mining categories (unmined lands, abandoned coal mines, and reclaimed coal mines) differed in pH, specific conductance, sulfate, iron, aluminum, and alkalinity for 122 streams in eastern Ohio. Aquifer rock type influenced pH, specific conductance, sulfate, iron, and alkalinity. Reclamation returned many components of acid mine drainage to near unmined levels, although sulfate and specific conductance were not improved. Acid mine drainage problems were less severe in watersheds underlain by the calcareous Monongahela Formation. These results should apply to other Appalachian coal regions having similar rock units. The water quality data distributions were neither consistently normal nor lognormal. Statistical tests utilizing ranks of the water quality data, instead of the data themselves, provided useful in analyzing the influences of mining category and rock type. (Author's abstract)

LOADING FUNCTIONS FOR PREDICTING NUTRIENT LOSSES FROM COMPLEX WATERSHEDS,
Clemson Univ., SC. Dept. of Agricultural Economics and Rural Sociology.
L. L. D. Delwiche, and D. A. Haith.
Water Resources Bulletin, Vol. 19, No. 6, p 951-959, December, 1983. 1 Fig, 8 Tab, 27 Ref.

Descriptors: *Water pollution sources, *Nonpoint pollution sources, *Nutrients, *Watersheds, Mathematical models, Load function, Croplands, Forests, Urban areas, Animal wastes, Effluents, Groundwater discharge, West Branch Delaware River, New York.

A loading function methodology is presented for predicting runoff, sediment, and nutrient losses from complex watersheds. Separate models are defined for cropland, forest, urban and barnyard sources, and procedures for estimating baseflow nutrients are provided. The loading functions are designed for use as a preliminary screening tool to isolate the major contributors in a watershed. Input data sources are readily available and the functions do not require costly calibrations. Data requirements include watershed land use and soil information, daily precipitation and temperature records and rainfall erosivities. Comparison of predicted and measured water, sediment, and nutrient runoff fluxes for the West Branch Delaware River in New York, indicated that runoff was underpredicted by about 14% while dissolved nutrients were within 30% of observed values. Sediment and solid-phase nutrients were overpredicted by about 50%. An annual nutrient budget for the West Branch Delaware River showed that cornland was the major source of sediment, solid-phase nutrients, and total phosphorus. Waste water treatment plants and ground water discharge contributed the most dissolved phosphorus and dissolved nitrogen, respectively. (Author's abstract)

THROUGHFALL PH: EFFECT OF PRECIPITATION TIMING AND AMOUNT,
Commonwealth Scientific and Industrial Researc
Organization, Canberra (Australia). Div. of Wat
and Land Resources.
I. D. Moore.
Water Resources Bulletin, Vol. 19, No. 6, p 96
965, December, 1983. 3 Fig, 23 Ref.

Descriptors: *Hydrogen ion concentration, *Pr
cipitation, *Throughfall, *Acid rain, Bufferin
Deciduous forests, Canopy, Dryfall, Leaves, Ke
tucky.

Precipitation, throughfall, and stream pH we
measured weekly over a 27-week period in 1982 c
the Little Millseat watershed in eastern Kentuck
The average pH values over the study period we
4.3, 4.9, and 6.4, respectively, indicating significa
buffering as water moved from the atmospher
through the deciduous canopy, and through
over the soil to the stream. Regression analys
demonstrated that the timing and amount of pr
cipitation were important factors influencing th
pH of the throughfall. Weekly precipitation a
the three-week average precipitation were statis
cally significant variables, explaining 53% of th
variance in the observed throughfall pH. Precipit
tion pH was not a statistically significant variab
for this watershed and sampling period. Durin
dry periods with little precipitation, the deciduo
canopy had a high buffering capacity and throug
fall pH remains high (about 6.0) even though th
precipitation pH is low. As the frequency, duratio
and amount of precipitation increases the bufferi
capacity remains high until the accumulated dr
fall deposition is washed from the leaf surfaces, a
the leaching rates of plant chemicals from th
leaves are exceeded by the supply rate of acid
precipitation. At this time a large volume of acid
precipitation is input to the system with little bu
fering capacity by the canopy, so the throughfa
pH decreases rapidly, approaching that of the in
dent precipitation. After major precipitation ever
it takes some time for the canopy to recover a
for nutrients and plant chemicals to be replaced
the leaves, and for dryfall to build up on le
surfaces before throughfall pH begins to increas
This time delay varied from about one to thr
weeks, depending on the amount of precipitatio
during this recovery period. (Moore-IVI)

Descriptors: *Water quality, *Coal minin
Groundwater pollution, Variogram, Geostatisti
Environmental effects.

Large variability of water quality data often mak
it difficult to judge whether or not the conditio
in an aquifer or a stream are deteriorating
improving. A technique for separation of var
grams into positive and negative difference comp
nents is proposed. This technique was applied
water quality data from a reclaimed site that h
been used for coal mining. Distribution of grou
water elevations in time at the experimental s
showed that highest water levels on both the str
mined and deepmined areas generally follow t
occurrence of major storms, while lowest lev
appeared to result from 60-day or longer dry spe
with rains less than 25 mm. Despite much scat
and variability in the data, sulfate concentratio
were most highly correlated with other variab
and could be used to estimate each of the oth
chemical parameters for selected sampling sit

Therefore, sulfate concentrations were used to illustrate the novel technique designed to show if the water quality was improving or deteriorating. The results showed conclusively that overall water quality improved on the stripmined and undisturbed area, remained about the same in the deepmined area, and declined in the seep and stream. ACID SNOWPACK CHEMISTRY IN PENNSYLVANIA, 1979-81,
Pennsylvania State Univ., University Park. School of Forest Resources.
D. R. DeWalle, W. E. Sharpe, J. A. Izbicki, and D. L. Wirries.
Water Resources Bulletin, Vol. 19, No. 6, p 993-1001, December, 1983. 8 Fig, 5 Tab, 16 Ref.

Descriptors: *Snowpack, *Acid precipitation, *Pennsylvania, *Hydrogen ion concentration, Nitric acid, Sulfates, Sulfur dioxide, Dust, Limestone, Dolomite, Quarries, Water pollution sources.

Snowpack chemistry was evaluated with repeated surveys at 30 sampling sites across Pennsylvania during 1979-81. The mean snowpack pH of 4.25 of 280 samples was largely due to H(+) from nitric acid. Snowpack sulfates were high, especially in the southwest sector of the state, where SO2 emissions were also high. Rain-on-snow and coastal storm snowpacks produced higher snowpack pH. Localized increases in snowpack pH were found due to additions of dust from limestone and dolomite quarry operations, especially in the central Ridge and Valley Province. Acid loading on the landscape from snow in Pennsylvania is controlled by the total amount of snowfall as well as variations in concentrations of chemical constituents. (Author's abstract)

EFFECTS OF CLEARCUTTING AND SLASH BURNING ON STREAMWATER CHEMISTRY AND WATERSHED NUTRIENT BUDGETS IN SOUTHWESTERN BRITISH COLUMBIA,
British Columbia Univ., Vancouver. Faculty of Forestry.
M. C. Feller, and J. P. Kimmins.
Water Resources Research, Vol. 20, No. 1, p 29-40, January, 1984. 2 Fig, 8 Tab, 63 Ref.

Descriptors: *Clear-cutting, *Slash burning, *Water chemistry, *Stream pollution, *British Columbia, Nutrients, Water pollution sources, Sodium, Potassium, Magnesium, Chloride, Phosphorus, Calcium, Nitrates.

Two small forested watersheds near Haney in southwestern British Columbia were partially clearcut, and the slash on one of them was subsequently burned. Streamwater chemistry was monitored in these treated watersheds and an undisturbed control watershed for 2 years prior to treatment and up to 9 years after treatment. The chemical parameters that were studied responded differently to the treatments, but there was a general pattern of increased concentrations and fluxes in streamwater for the first 2-3 years following treatment followed by a decline to, and sometimes below, pretreatment values. The most pronounced increases were observed for K and NO3. It was not possible to determine the exact causes of these changes in concentrations and fluxes, due to the great variability in the ecosystems present. This variability precluded determination of statistically significant changes in annual terrestrial nutrient fluxes and pools. Stream nutrient exports usually were <10 kg/ha/yr for each of N, P, K, and Mg, <20 kg/ha/yr for Na and Cl, and <30 kg/ha/yr for Ca. These values were considerably less than nutrient exports in harvested logs and in losses to the atmosphere during the slashburn. Clearcutting and burning caused greater nutrient losses than clearcutting alone, particularly in the case of N, where the clearcutting and clearcutting and burning treatments resulted in total losses of 245 kg/ha and 1293 kg/ha, respectively, for the first two years after treatment. LAND USE PRESSURES ON COASTAL ESTUARIES IN ATLANTIC CANADA,
Dalhousie Univ., Halifax (Nova Scotia). Inst. for Resource and Environmental Studies.
G. E. Beanlands.
Coastal Zone Management Journal, Vol. 11, No. 1-2, p 117-132, 1983. 2 Fig, 8 Tab, 13 Ref.

Descriptors: *Estuaries, *Water pollution sources, *Land use, *Nova Scotia, *New Brunswick, *Prince Edward Island, Water pollution effects, Shellfish, Aerial photography.

Land-use pressures on estuarine resources were studied in the three Maritime Provinces of Canada (Nova Scotia, New Brunswick, Prince Edward Island). The first phase involved the initial identification of estuaries in the study area through stereoscopic interpretation of recent aerial photographs. The second phase involved the determination of land and water uses associated with each estuary. Various human activities were identified on the photographs and classified according to 14 major types of developments. This major breakdown was further refined by the addition of sub-categories related to intensity of use, for a total of 22 development types. The only regionally-based and consistent indicator of the biological quality of nearshore waters, including estuaries, is that provided by the shellfish pollution monitoring program of the federal government. As of 1977, over 200 areas in the Maritime Provinces were closed to the harvesting of shellfish. The incidence of pollution ranges from 80% of those estuaries supporting industrial activity to 47% of those influenced by recreational cottages. Only 17.7% of development-free estuaries were closed to shellfish harvesting. Forty-two percent of the estuaries suppporting one type of use were contaminated compared with 100% contamination of those influence by seven or more types of human activity. Given that 74% of the estuaries in the region have not yet undergone complex and intensive development, every effort should be made to prevent a further deterioration of this valuable resource base before remedial measures are impossible. (Moore-IVI)

OIL AND GREASE IN URBAN STORMWATERS,
California Univ., Los Angeles. School of Engineering and Applied Science.
M. K. Stenstrom, G. S. Silverman, and T. A. Bursztynsky.
Journal of Environmental Engineering, Vol. 110, No. 1, p 58-71, February, 1984. 3 Fig, 9 Tab, 30 Ref.

Descriptors: *Oil, *Grease, *Storm water, *Water pollution sources, *Land use, Rainfall, Water pollution control, Simulation, Richmond, California, San Franciso Bay.

A study of oil and grease in urban stormwaters was performed on a small watershed in Richmond, California, with the objective of determining the amount of oil and grease discharged into San Francisco Bay. Five sampling stations were selected at various places in the watershed that were indicative of specific land uses, and runoff from seven storms was samples and analyzed. The results of the survey indicated that oil and grease concentration was highly dependent upon land use, ranging from 4.1 mg/L in residential areas to 15.3 mg/L in parking lots. A statistical analysis of oil and grease and storm characteristics showed that oil and grease concentration was independent of all storm characteristics, except that mass of oil and grease discharged was proportional to total rainfall. Qualitative analysis of the oil and grease by gas chromatography indicated that it most resembled used automobile crankcase oil. Several samples showed evidence of spills of specific compounds. A simulation of management techniques indicated that a 90% reduction in discharge from commercial properties and parking lots, which represented only 9.6% of the total surface area, would result in a 53% reduction in total oil and grease discharge. Growth simulation predicted a potential 27% increase in discharge if 5% of the watershed were converted from open land to commercial property. (Author's abstract)

HISTORY OF PHOSPHORUS LOADING TO ONONDAGA LAKE,
Allied Corp., Jamesville, NY.
S. P. Devan, and S. W. Effler.
Journal of Environmental Engineering, Vol. 110, No. 1, p 93-109, February, 1984. 10 Fig, 2 Tab, 45 Ref.

Descriptors: *Phosphorus, *Onondaga Lake, *New York, Phytoplankton, Nutrients, Fate of pollutants, Lake restoration, Water pollution control, Calcium, Eutrophication, Sediments, Pollution load, Lake Ontario.

The history of phosphorus loading to, and efflux from, Onondaga Lake, New York, is presented for a 12-yr period (1970-1981), during which several phosphorus management measures were taken. A ten-fold reduction in phosphorus loading since 1970 has been achieved through implementation of reclamation measures, which included a ban on high phosphorus detergents and the addition of secondary and tertiary processes at the adjoining sewage treatment plant. Significant reductions in lake phytoplankton concentrations have not accompanied the reduction in phosphorus loading, indicating the lake remains nutrient-saturated. An unusually high fraction of phosphorus received by the lake is retained, apparently as a result of enhanced phosphorus deposition associated with the industrial loading of calcium from an adjoining chloralkali manufacturer. One-tenth of the reported substantial reduction in phosphorus loading to Lake Ontario from 1970-1979 is attributable to the reduction in loading to Onondaga Lake. The nature of the phosphorus associations in the lake's sediments indicates that sediment interactions should not act to compensate for further reductions in external phosphorus loading. CADMIUM ADSORPTION BY AEROBIC LAKE SEDIMENTS,
Oregon State Univ., Corvallis. Dept. of Civil Engineering.
J. O. Wiley, and P. O. Nelson.
Journal of Environmental Engineering, Vol. 110, No. 1, p 226-243, February, 1984. 9 Fig, 7 Tab, 51 Ref.

Descriptors: *Cadmium, *Lake sediments, *Adsorption, Fate of pollutants, Hydrogen ion concentration, Ligands, Sediments, Iron, Manganese, Partical size, Chemical speciation, Suspended solids, Organic compounds.

Factors that influence the adsorption of cadmium on aerobic lake sediments were investigated, including sediment type, pH, and soluble ligand composition. Conditional adsorption constants were experimentally determined for sediments samples in native lake water from Sturgeon Lake, Oregon. Correlation of adsorption constant values with sediment characteristics including mean grain size, iron and manganese content, volatile solids content, and cation exchange indicated significant dependence only on mean grain size. Another approach, using specific geochemical phase adsorption constants from another study to assess that phase's contribution to adsorption, predicted that iron oxides controlled cadmium adsorption. A speciation-distribution model for cadmium in the water column indicated that the dominant chemical forms were the free cadmium ion and cadmium adsorbed to suspended solids. As pH increased from 5 to 9, the adsorbed fraction increased and the free ionic fraction decreased markedly. Organic ligand complexes were predicted to be the dominant soluble cadmium complex in the neutral pH range, while the cadmium carbonate dominated at pH 9. (Author's abstract)

CRITICAL POINT METHOD FOR MIXING ZONES IN RIVERS,
Gore and Storrie Ltd., Toronto (Ontario). Water Resources Div.
T. P. H. Gowda.

Journal of Environmental Engineering, Vol. 110, No. 1, p 244-261, February, 1984. 9 Fig, 4 Tab, 23 Ref.

Descriptors: *Mixing, *Path of pollutants, *Critical point, Effluents, Chlorine, Ammonia, Outfalls, Rivers.

Expressions for the coordinates of a critical point, occurring along a given lateral boundary of a limited use zone within a mixing zone below a bank outfall in a river channel, are developed. A family of curves is developed for a range of dimensionless coordinates of the critical point. An expression for allowable effluent concentration of a pollutant is obtained in terms of critical concentration and water quality criterion. A graphical procedure for determining the longitudinal boundary of a limited use zone is described. The predictions of the critical point method are validated using total residual chlorine distribution data from a natural stream. The application of the methodology is outlined in a step-by-step design procedure and illustrated by an example for ammonia. In general, the method is applicable to exponentially decaying nonconservative pollutants. (Author's abstract)

ELEVATED CONCENTRATIONS OF HUMIC SUBSTANCES IN A SEASONALLY ANOXIC HYPOLIMNION: EVIDENCE FOR CO-ACCUMULATION WITH IRON,
Freshwater Biological Association, Ambleside (England).
E. Tipping, and C. Woof.
Archiv fur Hydrobiologie, Vol. 98, No. 2, p 137-145, October, 1983. 4 Fig, 2 Tab, 24 Ref.

Descriptors: *Decomposing organic matter, *Hypolimnion, Thermal stratification, Seasonal variations, Iron, Accumulation, Sediments, Algae, Iron oxide, Esthwaite Water, Fate of pollutants.

Humic substances (HS) are a major fraction of soluble organic matter in natural waters. They influence the chemical speciation of metals, bind hydrophobic pollutants such as DDT, and play a significant role in environmental surface chemistry. HS are a potential hazard in waters used for domestic supply since they react with chlorine to yield trihalomethanes, possible carcinogens. For these reasons, factors which determine humic concentrations in natural waters are of wide relevance. Increases in the concentration of humic substances in the anoxic hypolimnion of Esthwaite Water are correlated with increases in the concentration of iron. This finding supports the theory of a mechanism whereby humic substances are accumulated by co-sedimentation with iron oxide particles. Subsequently the humic substances follow the movements of iron during its redox cycling in the hypolimnion and sediment. Unsuccessful attempts were made to distinguish epilimnetic and hypolimnetic humic substances by spectroscopic and gel chromatographic means. Therefore no evidence for an alternative mechanism of humic accumulation was found such as the anaerobic decomposition of sedimented dead algae. (Baker-IVI)

ENDOGENIC FLUX OF MANGANESE TO THE BOTTOM OF LAKE CONSTANCE,
Konstanz Univ. (Germany, F.R.). Fakultaet fuer Physik.
H.-H. Stabel, and J. Kleiner.
Archiv fur Hydrobiologie, Vol. 98, No. 3, p 307-316, November, 1983. 4 Fig, 1 Tab, 25 Ref.

Descriptors: *Manganese, *Fate of pollutants, *Bottom sediments, Lakes, Lake Constance, Sedimentation, Hypolimnion, Thermal stratification.

The manganese content of the sediment particles trapped at greater depths was generally enhanced relative to that found in the upper layers. Three reasons may be responsible for this. Degradation of oganic matter during the settling process, and redissolution of calcite in deeper layers may lead to a relative enrichment of more stable inorganic constituents. Resuspension of bottom sediments richer in Mn than the particles moving vertically from upper layers may occur. In addition, an eodogenic oxidation of Mn(2+) into Mn(4+) occurs within the hypolimnion of Lake Constance. The Mn(4+) precipitates, mainly gamma-MnOOH, add to the vertical flux of Mn-containing particles, deriving from planktonic and allochthonous sources. (Baker-IVI)

5C. Effects Of Pollution

THE RECOVERY OF THE BIOTIC COMMUNITY IN A LOTIC FRESHWATER HABITAT AFTER EXTENSIVE DESTRUCTION BY CHLORINE,
Hamburg Univ. (Germany, F.R.). Inst. fuer Hydrobiologie und Fischereiwissenschaft.
C. W. Heckman.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 2, p 207-226, 1983. 2 Fig, 2 Tab, 25 Ref.

Descriptors: *Biotic recovery, *Lotic environment, *Chlorine, Ecological effects, Aquatic populations, Population dynamics, Population exposure, Fauna, Residual chlorine.

The recovery of a temperate zone biotic community in a lotic freshwater habitat after acute chlorine poisoning was nearly completed in four months (May to September). The water flow facilitated the removal of the toxic residues of the chlorine and transported organisms from the intact community upstream into the impoverished habitat. The first aggregation in the ditch after the chlorine was eliminated consisted of survivors, including members of species that failed to produce new generations. These were joined by pioneer species of the families Simulidae and Chironomidae, the larvae of which appeared in massive numbers. This aggregation was displaced by a more diverse fauna as the macroflora and microbiota re-established themselves, providing food and anchorage for the invertebrates. The populations of large fishes are slowest to return because a considerable amount of time is required for the migration and growth of the recruits. While the chronic intoxication of a habitat produces changes in community structure, an acute poisoning is followed by a nearly complete restoration of the original biota, the recovery time being determined by the proximity of recruits for resettlement. LAKE ONTARIO'S FISH - HOW THE ALMOST GOT AWAY,
S. Peterson.
Environment, Vol. 25, No. 9, p 25-32, Novembe 1983. 6 Fig, 32 Ref.

Descriptors: *Fish, *Water pollution effects, *Lak Ontario, Great Lakes, Polychlorinated biphenyl Dioxin, Mirex, Salmon, Fisheries, Pesticides, Lam prey, Alewife, Smelt.

The history of fish populations in Lake Ontario reviewed. Two hundred years ago the lake su ported what has been thought to be the world largest population of land-locked salmon. By th end of World War II practically all commerciall valuable fish species in this lake were gone. Cu rently sportsmen again are catching trophy siz chinook salmon in that lake, but now these fish a contaminated with pollutants which renders the unsafe for consumption more than once a mont and unsafe for children and women of child bea ing age in any amount. As lands bordering Lak Ontario were cleared and settled, nearly ever sizable stream was dammed in order to pow industrial mills. Dams and pollution took their to on the lake population. The next happening w direct exploitation by developing gill-net fisheri One of the most dramatic results of man's impa on the Great Lakes has been the spectacular su cess of several invading marine species of fis which have profoundly altered the ecology of th lakes. Among these are the lamprey, alewife an smelt. The presence in the lake of PCBs, dioxin and mirex are of particular concern to area re dents and fish managers. (Baker-IVI)

NICKEL TOXICITY TO ESTUARINE/MARIN FUNGI AND ITS AMELIORATION BY MA NESIUM IN SEA WATER,
New York Univ., NY. Lab. of Microbial Ecolog
H. Babich, and G. Stotzky.
Water, Air, and Soil Pollution, Vol. 19, No. 2, 193-202, 1983. 2 Fig, 5 Tab, 22 Ref.

Descriptors: *Seawater, *Nickel, *Toxicit *Fungi, Sodium, Chloride, Magnesium, Salinit Mycelial, Marine plants, Estuarine environmen

Mycelial growth rates of five estuarine/mari fungi were determined on the non-marine and the marine nutrient medium in the absence a presence of progressively increasing levels nickel. In the absence of nickel growth rates we greater on the marine medium. Furthermore, t fungi tolerated nickel better when exposed on t marine than on the non-marine medium. Wh grown on the non-marine medium amended wi nickel, incipient growth inhibition for Pleospo vagens was evident at a concentration between and 50 ppm Ni for Dendryphiella salina, Aster myces cruciatus, and Dreschlera halodes at 50 pp nickel, and for Buergenerula spartinae at a conce tration greater than 50 ppm Ni. Total grow inhibition on the non-marine medium occurred 50 ppm Ni for P. vagens, at 100 ppm Ni for salina, B. spartinae, and A. cruciatus, and at 2 ppm Ni for D. halodes. When grown on t marine medium, incipient growth inhibition o curred at 50 ppm Ni for P. vagens, A. cruciat and D. halodes, at 100 ppm Ni for D. salina, and 250 ppm Ni for B. spartinae. Total growth inhi

ion occurred at 500 ppm Ni for P. vagens, D. alina, B. spartinae, and A. cruciatus, and D. hodes exhibited some growth even at 500 ppm Ni. The ameliorating effect of seawater or salinity on he toxicity of Ni to mycelial proliferation was related to the Mg, rather than to the Na or Cl ions n the marine systems. The mechanism by which eawater reduced Ni toxicity is apparently different from the mechansism whereby seawater reduced the toxicity of Cd and Hg. (Baker-FRC)

POTENTIAL PHYTOTOXICITY OF DIQUAT ACCUMULATED BY AQUATIC PLANTS AND SEDIMENTS,
York Univ., Downsview (Ontario). Dept. of Biology.
B. C. Birmingham, and B. Colman.
Water, Air, and Soil Pollution, Vol. 19, No. 2, p 123-131, 1983. 2 Fig, 4 Tab, 24 Ref.

Descriptors: *Phytotoxicity, *Aquatic plants, *Sediments, *Organic compounds, Herbicides, Diquat, Bipyridilium, Lake sediment, Bottom sediment, Bioassays, Water pollution effects.

The adsorption and desorption of Reglone A was studied on freshwater algae grown in culture, Eurasian water milfoil, and greenhouse soil-sand mixture. The data was needed to examine the potential for phytotoxicity of diquat residues in aquatic ecosystems. The nitrogen fixing blue-green alga, Anabaena flos-aquae and a duckweed were used as bioassay organisms to test for residual phytotoxicity once the diquat was bound to the soil. Reglone inhibited the growth of blue-green algae at concentrations greater than 0.03 ppm. Eukaryotic algae were less sensitive, growth of Navicula pelliculose was inhibitied at concentrations exceeding 0.3 ppm and Chlorella vulgaris was unaffected by 3 ppm Reglone. In the presence of soil, growth inhibition by Reglone was eliminated. Reglone was added to a water-soil mixture system up to 334 ppm to simulate chronic usage. Significant growth inhibition occurred to both bioassay plants in soil treated with 33.4 ppm Reglone and the 334 ppm treatment was lethal. It is suggested that residual phytotoxicity becomes apparent in this soil system at about 7% of the diquat adsorption capacity. The Reglone adsorption-desorption isotherm of a natural, organic lake sediment was measured to predict the number of Reglone treatments at the recommended application rate before residual phytotoxicity would become apparent. DELAYED TOXICITY OF CARBOFURAN IN FRESHWATER TELEOSTS, CHANNA PUNCTATUS (BLOCH) AND ANABAS TESTUDINEUS (BLOCH),
Visva Bharati Univ., Santiniketan (India). Environmental Toxicology Lab.
N. B. Jash, and S. Bhattacharya.
Water, Air, and Soil Pollution, Vol. 19, No. 3, p 209-213, 1983. 2 Tab, 10 Ref.

Descriptors: *Toxicity, *Organic compounds, *Pesticides, *Fish, Water pollution effects, Organophosphates, India, Aquatic life.

In vitro inhibition of brain acetylcholinesterase from Channa punctatus and Anabas testudineus was compared between control and Carbofuran treated fish. A dose dependent in vivo inhibition was recorded in both species of fish. On transfer to pesticide free fresh water there was immediate recovery of AChE activity within 30 days only in those fish treated with the highest dose of Carbofuran. During the sojourn of fish in Carbofuran free water there appears to be a gradual dissociation of the incorporated inhibitor from the enzyme, which occurs at a faster rate in fish treated with highest concentrations of carbofuran. Delayed toxicity of the lower concentrations of carbofuran was more conspicuous in Channa punctatus although it is apparently more resistant to carbofuran than Anabas testudineus. (Baker-FRC)

PERIPHYTON BIOMASS AND SPECIES COMPOSITION IN A COASTAL RAINFOREST STREAM IN BRITISH COLUMBIA: EFFECTS OF ENVIRONMENTAL CHANGES CAUSED BY LOGGING,
Fisheries and Marine Service, Vancouver (British Columbia). Vancouver Lab.
K. S. Shortreed, and J. G. Stockner.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 1887-1895, November, 1983. 6 Fig, 1 Tab, 26 Ref.

Descriptors: *Environmental effects, *Coastal streams, *Logging, *British Columbia, Carnation Creek, Phosphorous, Biomass, Algae, Chlorophyta, Diatoms, Solar radiatior., Periphyton, Clear-cutting, Water temperature.

Periphyton biomass, species composition, and accumulation rates on Plexiglas substrates were determined in a 6-yr study from 1974 to 1979 in Carnation Creek, Vancouver Island, British Columbia. During the first 2 years of the study, the watershed was unlogged. Clearcut logging during the remainder of the study resulted in increases in light intensity of over 100% at some sites, with slight increases in stream temperature (2-3 degrees C in summer) and increases in some dissolved ion concentrations. Phosphorus concentrations were similar throughout. Diatoms were the most common class of algae, and Achnanthes minutissima and Synedra rumpens were the most common diatoms. Filamentous chlorophytes (predominantly Mougeotia sp. with some Draparnaldia sp., Spirogyra and Zygnema sp.) occurred sporadically throughout the study but were more common after logging, primarily as a result of increased light intensity. The highest recorded periphyton biomass and accumulation rates occurred after logging. Post-logging values were generally similar to those recorded prior to logging due to the lack of increased phosphorus concentrations after logging. (Murphy-IVI)

CONTAMINANT ACCUMULATION AND PHYSIOLOGICAL RESPONSE IN RAINBOW TROUT (SALMO GAIRDNERI) REARED ON NATURALLY CONTAMINATED DIETS,
Guelph Univ. (Ontario). Dept. of Nutrition.
J. W. Hilton, P. V. Hodson, H. E. Braun, J. L. Leatherland, and S. J. Slinger.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 1987-1994, November, 1983. 6 Tab, 21 Ref.

Descriptors: *Physiological response, *Trout, *Bioaccumulation, Salmon, Fish food, DDT, Chlordane, Dieldrin, Polychlorinated biphenyls, Aquaculture, Mirex, Lake Michigan, Lake Ontario, Pacific Ocean.

Juvenile rainbow trout were reared for 24 weeks on practical-type diets formulated with fish meals of coho salmon (Oncorhynchus kisutch) from Lake Michigan, Lake Ontario, and the Pacific Ocean. Levels of contaminants (DDT, chlordane, dieldrin, mirex and polychlorinated biphenyls) increased 10-fold from control and Pacific Ocean salmon-based diets to Lake Ontario salmon-based diets. Rainbow trout accumulated contaminants in direct proportion to dietary levels. There were no significantly differences in the final body weights, feed to gain ratios, or mortality rates of the trout. There were no signs of abnormal behavior or histopathological abnormalities. There were no signs of thyroid hyperplasia or significant decline in serum T3 or T4 levels with increasing dietary contaminant levels. The rainbow trout were not affected by the uptake and accumulation of contaminants. The trout did not regulate their body burden of contaminants, which could be toxic and adversely affect their reproductive cycle. The final concentrations of mirex and PCBs in Lake Ontario-fed fish exceeded the allowed limits to protect human health. The fish meals produced from Lake Ontario salmon are unsuitable as a source of feed for aquaculture of rainbow trout intended for human consumption. (Murphy-IVI)

GEOTHERMAL EFFECTS ON STREAM BENTHOS: SEPARATE INFLUENCES OF THERMAL AND CHEMICAL COMPONENTS ON PERIPHYTON AND MACROINVERTEBRATES,
California Univ., Berkeley. Div. of Entomology and Parasitology.
G. A. Lamberti, and V. H. Resh.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 1995-2009, November, 1983. 8 Fig, 3 Tab, 40 Ref. OWRT project A-084-CAL, Water Resources Center Project UCAL-WRC-W-612.

Descriptors: *Benthos, *Thermal springs, *Environmental effects, *Geothermal fluids, *Stream biota, Thermal stress, Chemical composition, Invertebrates, Geothermal power, Big Sulphur Creek, The Geysers, California.

The largest geothermal energy development in the world is located at The Geysers in northern California, but the full development of geothermal resources at The Geysers and in other areas has been delayed because of potential environmental impact, especially on aquatic biota. Stream microcosms were used in situ to evaluate the separate effects of the thermal and chemical components of geothermal fluids from natural hot springs on benthic microorganisms and macroinvertebrates of Big Sulphur Creek, a third-order stream at The Geysers. The thermal component of geothermal fluids had greater influence than the chemical component in determining benthic community features. A natural input of geothermal fluids elevated both the temperature (by 7.5 degrees) and chemical levels (boron by 10 times, NO3-N by 4 times, PO4-P by 2 times), increased benthic chlorophyll a by 40 times, bacterial numbers by 10 times, and macroinvertebrate density by 2 times. Heating of non-geothermal water by 8 degrees increased chlorophyll a by 40 times and bacterial numbers by 2 times, but macroinvertebrate density declined by one fourth. Cooling of geothermal water by 14.5 degrees reduced algal productivity but increased macroinvertebrate density by 70 times. Naturally occurring geochemical concentrations apparently can be tolerated by aquatic organisms, but changes in water temperature significantly alter benthic community structure. (Murphy-IVI)
W84-03019

INFLUENCE OF DETERIORATING WATER QUALITY ON GROWTH AND DEVELOPMENT OF CHUM SALMON (ONCORHYNCHUS KETA) LARVAE IN A JAPANESE-STYLE KEEPER CHANNEL,
Department of Fisheries and Oceans, Nanaimo (British Columbia). Pacific Biological Station.
R. A. Bams, and C. N. H. Lam.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 11, p 2098-2104, November, 1983. 1 Fig, 2 Tab, 27 Ref.

Descriptors: *Water pollution effects, *Salmon, *Larvae, *Keeper channels, Aquaculture, Growth, Dissolved oxygen, Fish farming, Ammonia.

Chum salmon (Oncorhynchus keta) larvae were incubated in gravel filled cages placed in two experimental Japanese-style keeper channels having 40 and 80 L/min total flow, at three successive locations having 0, 46,000, and 92,000 eggs (or alevins) upstream. Minimum dissolved oxygen was 6.21 mg/L. Maximum un-ionized ammonia was 0.18 microgram/L. The pH varied from 7.18 to 6.83, and temperature ranged from 7.8 to 8.2 C. Preemergent fry showed small but significant decreases in mean fork length, with increasing distance along both channels 50 days after hatching. Weights decreased similarly but nonsignificantly in both channels. Stage of development was constant in all locations except the bottom location of the

low-flow channel, which showed a significantly delay. Survival was uniformly high with no differential mortality among locations or flow rates. The deteriorating water quality measurably reduced larval development rate, growth rate, and yolk-conversion efficiency. The main effective factor was dissolved oxygen. Standard channel loading and flow criteria are adequate for short incubation channels only. (Murphy-IVI)

ACUTE EFFECTS OF TOXAPHENE AND ITS SEDIMENT-DEGRADED PRODUCTS ON ESTUARINE FISH,
South Carolina Univ., Columbia.
H. W. Harder, T. V. Carter, and T. F. Bidleman.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 12, p 2119-2125, December, 1983. 4 Fig, 1 Tab, 23 Ref.

Descriptors: *Toxaphene, *Estuarine environment, *Toxicity, *Fish, Degradation products, Pesticide residues, Sediments, Bioassay, Bioaccumulation.

The acute effect of toxaphene and the dechlorinated products that are formed in reducing sediments were determined for two estuarine fish, spot (Leiostomus xanthurus) and white mullet (Mugil curema). The reductively dechlorinated mixture was prepared by incubating toxaphene with anoxic salt marsh sediment for three weeks and isolating the products, then analyzed by packed and glass capillary gas chromatography. The 96-h LC50 for toxaphene was 0.92 and 2.88 micrograms/L for spot and mullet, respectively. Sediment degraded toxaphene was almost as toxic to spot (LC50 = 1.10 microgram/L) as the parent pesticide. The mullet were three times more susceptible to the degraded form (LC50 = 1.02 microgram/L). Bioaccumulation was similar for both forms of toxaphene, with factors of 2000-6000 over the 96-h exposure period. Short-term degradation of toxaphene in anoxic sediments does not apear to reduce its toxicity; the degraded toxaphene produced has as much potential for causing acute poisoning to fish as the parent pesticide. Analytical searches for toxaphene residues in environmental samples should not be restricted to gas chromatography patterns matching those of the parent compound but should also consider the degraded toxaphene fingerprints. (Murphy-IVI)

RETROSPECTIVE ANALYSIS OF THE RESPONSE OF SAGINAW BAY, LAKE HURON, TO REDUCTIONS IN PHOSPHORUS LOADINGS,
Environmental Research Lab.-Duluth, Grosse Ile, MI. Large Lakes Research Station.
V. J. Blerman, Jr., D. M. Dolan, R. Kasprzyk, and J. L. Clark.
Environmental Science and Technology, Vol. 18, No. 1, p 23-31, January, 1984. 7 Fig, 5 Tab, 40 Ref.

Descriptors: *Saginaw Bay, *Lake Huron, *Phosphorus, Biomass, Chlorophyll a, Phytoplankton, Cyanophyta, Turbidity, Sediment resuspension, Odor, Drinking water.

Control of phosphorus inputs to lakes is one of the principal means for attempting to reverse the symptoms of cultural eutrophication. Through a retrospective (1974-1980) analysis of Saginaw Bay, Lake Huron, loadings to the bay from the Saginaw River for total phosphorus and dissolved ortho phosphorus were 55% and 72% lower, respectively, in 1980 than in 1974. In the most seriously degraded area of the bay, spring and fall total phosphorus concentrations decreased by 1% and 14%, respectively, while chlorophyll a concentrations decreased by 53% and 61% in the same seasons. The corresponding decreases for inverse Secchi depth were 0% and 17%. Sediment resuspension due to wind-induced wave action was the probable cause for the anomalous relationship between chlorophyll a and total phosphorus concentrations, and the lack of response of inverse Secchi depth. A substantial decrease in threshold odor in the municipal water supply was correlated with a decrease in blue-green dry weight biomass concentration. The change was poorly correlated with blue-green cell number, total phytoplankton dry weight biomass, or chlorophyll a concentrations. (Murphy-IVI)

FISH/SEDIMENT CONCENTRATION RATIOS FOR ORGANIC COMPOUNDS,
Harvard School of Public Health, Boston, MA. Interdisciplinary Programs in Health.
M. S. Connor.
Environmental Science and Technology, Vol. 18, No. 1, p 31-35, January, 1984. 3 Fig, 1 Tab, 32 Ref.

Descriptors: *Fish, *Sediments, *Organic compounds, Chlorinated hydrocarbons, Hydrocarbons, Water pollution effects, Mollusks, Crustaceans, Mathematical studies, Partition coefficients, Hydraulic retention time, Flushing capacity.

Applying a bioconcentration factor directly to predict the potential for the contamination of fish by toxic organic compounds may be insufficient in the field. Partition coefficients make accurate predictions of contamination in short-term laboratory tests, but in the environment, biological and physical factors play an important role. The concentration ratio of chlorinated or polynuclear aromatic hydrocarbons in fish to the sediments from their habitat increases with hydraulic retention time of the basin. Fish/sediment ratios for chlorinated hydrocarbons are about three orders of magnitude higher than for aromatic hydrocarbons with the same octanol-water partition coefficient. Normalizing for sediment concentrations and animal concentrations of chlorinated aromatic hydrocarbons, the body burdens of polynuclear aromatic hydrocarbons in different phyletic groups are consistent with the inverse of their mixed-function oxygenase activity. The order for the concentrations is mollusks > polychaetes = crustaceans > fish. The consistent behavior of classes of compounds allows extrapolation from data for individual compounds to a variety of pollutants in aquatic environments where the flushing capacity has been determined. CHEMISTRY AND MICROBIOLOGY OF A SEWAGE SPILL IN SOUTH SAN FRANCISCO BAY,
Geological Survey, Menlo Park, CA.
J. E. Cloern, and R. S. Oremland.
Estuaries, Vol. 6, No. 4, p 399-406, December, 1983. 3 Fig, 2 Tab, 25 Ref.

Descriptors: *Wastewater, *Spills, *Water pollution effects, Bays, San Francisco Bay, Estuaries, Wastewater treatment facilities, Primary wastewater treatment, Secondary wastewater treatment, Dissolved oxygen, Methane, Ammonia.

The breakdown of a waste treatment plant resulted in the discharge of a large volume of primary treated sewage into a tributary of South San Francisco Bay, California during three weeks of September 1979. Chemical and microbial changes occurred within the tributary as decomposition and nitrification depleted dissolved oxygen. Associated with anoxia were relatively high concentrations of particulate organic carbon, dissolved carbon dioxide, methane, C2H2, ammonia and fecal bacteria along with low phytoplankton biomass and photosynthetic oxygen production. After the sewage treatment plant resumed its normal activities the Coyote Creek experienced radical biochemical changes as it shifted from anaerobic to aerobic conditions. Most rapid changes were noted in CH4 and C2H4 concentrations. Within two weeks particulate organic carbon decreased and dissolved oxygen increased to apparently normal levels. The rapid chemical changes were accompanied by increases in phytoplankton biomass. Two principles associated with the discharge of sewage into estuaries were exemplified by the study: first, the finite capacity of receiving waters to assimilate wastes, and secondly, that the aquatic ecosystems are resilient, even to extreme perturbations. EFFECTS OF INDUSTRIAL BOILER BLOWDOWN DISCHARGES ON STREAMS,
Tennessee Dept. of Public Health, Nashville.
J. C. Spangler.
Pollution Engineering, Vol. 25, No. 9, p 44-45, 1983. 2 Fig.

Descriptors: *Wastewater treatment, *Monitoring, Acidity, Sulfites, Sulfates, Dissolved solids, Oxygen demand, Suspended solids, Boiler blowdown.

Boiler blowdown is primarily for elimination of boiler sludge and dissolved solids. Before the blowdown is discharged, it should be treated to comply with effluent guidelines instead of diluting the discharge with other discharges. The following parameters are recommended for monitoring and reporting on an individual case basis for boiler blowdown discharges to other than publicly owned treatment works: biochemical oxygen demand, total suspended solids, total dissolved solids, pH, sulfites, chemical oxygen demand, settleable solids, ammonia, oil and grease, and sulfates. PREDICTING ALGAL STIMULATORY PROPERTIES OF WASTEWATER,
Massachusetts Univ., Amherst.
N. M. Ram, and P. E. Austin.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1099-1110, October, 1983. 6 fig, 2 Tab, 19 Ref. WDWPC project 80-30.

Descriptors: *Prediction, *Algae, *Biological properties, *Wastewater, Municipal Sewage, Inorganic nitrogen, Inorganic phosphorus, Algal growth, Biodegradation.

Discharge of wastewater effluent into the aquatic environment is of environmental concern because of the resulting eutrophication or nutrient of receiving waters leading to decreased water quality. The Algal Assay: Bottle Test (AA:BT) is a useful tool in evaluating the bioavailable nutrients in natural waters and wastewater effluents. The AA:BT did not permit sufficient organic mineralization during incubation, owing to the exclusion of heterotrophic bacteria and protozoa by the test procedure. This occurrence could result in an underestimation by the AA:BT of the algal growth potential occurring from the entry of a wastewater containing inorganic and organic nitrogen and phosphorus compounds into the aquatic environment. TEMPERATURE, PH, SALINITY, HARDNESS AND PARTICULATES MEDIATE NICKEL TOXICITY TO EUBACTERIA, AN ACTINOMYCETE, AND YEASTS IN LAKE, SIMULATED ESTUARINE, AND SEA WATERS,
New York Univ., NY. Lab. of Microbial Ecology
H. Babich, and G. Stotzky.
Aquatic Toxicology, Vol. 3, No. 3, p 195-208, April, 1983. 10 Fig, 24 Ref. EPA grant R808329.

Descriptors: *Temperature, *Hydrogen ion concentration, *Salinity, *Hardness, *Particulate matter, *Nickel, *Toxicity, *Eubacteria, *Actinomycete, *Yeasts, *Lakes, *Estuarine environment, *Seawater, Heavy metals, Water pollution effects, Water quality standards, Environmental factors.

Little is known about the effects of Ni on marine microorganisms. Even less is known about the influence of abiotic environmental factors on the toxicity of Ni to marine organisms, especially to the microbiota. Information on the survival of some eubacteria, an actinomycete, and yeasts after acute and chronic exposures to nickel (Ni) in lake, simulated estuarine, and sea waters and the influence of environmental factors on Ni toxicity will help to determine water quality standards. Criteria that do not adequately consider differences in the physicochemical characteristics of various aquatic ecosystems will be over-protective for some ecosystems and under-protective for others. Nickel toxicity to microbes in marine systems is reduced by increasing the salinity, by decreasing the temperature, and by the incorporation of simulated

ediment. The toxicity of Ni to microbes in fresh vater is reduced by increasing the pH, by increasng the hardness, and by the incorporation of susended particulates. In chronic toxicity fresh vaters are more sensitive than marine waters to Ni ollution, as microbial survival is greater in marine han in fresh waters stressed with equivalent conentrations of Ni. RAINBOW TROUT AND HUMAN CELLS IN CULTURE FOR THE EVALUATION OF THE TOXICITY OF AQUATIC POLLUTANTS: A STUDY WITH CADMIUM,
Quebec Univ., Montreal. Dept. de Chemie.
M. Marion, and F. Denizeau.
Aquatic Toxicology, Vol. 3, No. 4, p 329-343, May, 1983. 4 Fig, 28 Ref.

Descriptors: *Rainbow trout cells, *Human cells, *Toxicity, *Aquatic pollutants, *Cadmium, Bioassay, Bioaccumulation, Detection limits, Water quality, Comparison studies, Correlation analysis.

Rainbow trout (RTG-2) and human skin epithelial cells (NCTC 2544) as bioassay organisms evaluated he toxicity of the aquatic pollutant cadmium (Cd). The cell lines were grown as monolayers at 15 RTG-2) and 37 degree C (NCTC 2544) in minimal ssential medium supplemented with 10% fetal ovine serum (FBS). RTG-2 and NCTC 2544 cells xposed to 100 ppb and 2.4 ppm Cd was mainained for a period of time sufficient for an inocuum of 105 cells (RTG-2) or 50,000 cells (NCTC 544) to reach confluence in the controls in a 60-m Petri dish: 20 days for RTG-2 and 9 days for NCTC 2544. Every 2 days (RTG-2) or every day NCTC 2544) the medium was renewed and 3 Petri dishes were used to determine the total proein, total DNA, total RNA content and the incorporation of H-3 thymidine in DNA and C-14 uriine in RNA. The cytotoxicity of Cd was apparent nly when the serum concentration in the medium vas reduced. With 1% FBS in the medium Cd nduced a dramatic inhibition in the increase of otal protein DNA and RNA content of RTG-2 ells. At 2.4 ppm, this occurred as early as 5 days protein and RNA) after Cd was added to the ultures. The incorporation of labelled precursors vas equally much lower in the treated samples (2.4 ppm) compared to the controls. At 100 ppb, only he incorporation of C-14 uridine in RNA was ffected after 10 days of exposure and persisted ntil the end of the experiment. NCTC 2544 cells ppeared to be more sensitive to cadmium than RTG-2 cells. At 2.4 ppm, as seen with trout cells, here was a severe depression in all the parameters. However, at 100 ppm, contrasting with RTG-2 ells, significant differences were at least on 4 arameters (protein, DNA, RNA and C-14 incorporation). The complete assessment of the reliabilty of cell culture systems for the evaluation of oxicity will be achieved through the establishment f a strong correlation between in vivo and in vitro esponses. This is considered an important step in he process of validation of the present bioassay ystem. (Murphy-IVI)

EFFECTS OF ACCUMULATED DIETARY KEPONE ON SPOT (LEIOSTOMUS XANTHURUS),
Virginia Inst. of Marine Science, Gloucester Point.
L. L. Stehlik, and J. V. Merriner.
Aquatic Toxicology, Vol. 3, No. 4, p 345-358, May, 1983. 5 Fig, 11 Tab, 33 Ref.

Descriptors: *Bioaccumulation, *Diets, *Kepone, *Spot, Biological effects, Fish toxins, Mortality, Water pollution effects.

The water, sediments and biota of the James River, n Virginia, are contaminated with organochlorine esticide Kepone (Chlordecone). Migratory fish ccumulate Kepone while they reside in the James River during the summer. The administration of Kepone on juvenile spot body burdens increased additively and equilibrium was not attained. When spot were fed a lethal concentration (3.3 micrograms/g) over 28 days, they accumulated an average of 2.7 micrograms/g (wet wt). Most developed muscular tetany, fractured vertebral centra, and abnormally thickened vertebrae. These symptoms developed over a 4-wk period until death. Spot fed lesser concentrations (0.59 and 0.30 microgram/g) accumulated 0.7 and 0.3 microgram/g over 56 days and developed similar bone damage. The percentage of collagen in vertebrae was significantly greater in the treated fish which had thickened bones. Spot that were held in the laboratory as controls for 5 wk had significantly lower collagen percentages than wild fish. Kepone accumulation is the likely mechanism for production of the bone deformities observed in fishes from the James River in 1971-1976. (Murphy-IVI)

RELATIVE LIVER WEIGHTS AND XENOBIOTIC-METABOLIZING ENZYMES OF FISH FROM POLLUTED SURFACE WATERS IN THE NETHERLANDS,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
W. Slooff, C. F. Van Kreijl, and A. J. Baars.
Aquatic Toxicology, Vol. 4, No. 1, p 1-14, August, 1983. 5 Fig, 5 Tab, 24 Ref.

Descriptors: *Liver weights, *Xenobiotic compounds, *Metabolizing enzymes, *Fish toxins, *Water pollution, *Surface water, *Netherlands, Chemical wastes, Bioaccumulation, Bioindicator, Biological effects, Rhine River.

Organisms inhabiting the river Rhine are exposed to a wide variety of foreign organic chemicals. From laboratory experiments it is known that exposure to xenobiotic compounds often results in liver enlargement, usually associated with the induction or stimulation of hepatic enzyme activities. The somatic liver index (SLI) values were significantly greater in populations sampled from contaminated waters than in those from less polluted areas. The highest values from Rhine fish were (3.5) and the lowest for Lake Braassem fish were (1.5). Both biochemical and histological observations suggest that the liver enlargement is mainly caused by hypertrophy. The liver growth was accompanied by elevated hepatic enzyme activities. Like most other liver parameters, the SLI showed seasonal variations with the highest values in winter and the lowest in spring. Over the past 3 years there has been a decrease of the relative liver weight of Rhine and Meuse fish in time, which may reflect the improvement of the chemical water quality of these rivers. The SLI may be useful as an indicator of chemical water pollution. (Murphy-IVI)

BENTHIC MACROINVERTEBRATES AND WATER QUALITY ASSESSMENT: SOME TOXICOLOGICAL CONSIDERATIONS,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
W. Slooff.
Aquatic Toxicology, Vol. 4, No. 1, p 73-82, August, 1983. 3 Tab, 35 Ref.

Descriptors: *Benthic fauna, *Macroinvertebrates, *Water quality, *Toxicity, Water quality standards, Bioindicator, Chemical wastewater.

The distribution of benthic macroinvertebrates is generally considered to be indicative for the chemical quality of surface waters. However, little is known about their tolerance to chemical pollutants. To give further information on the tolerance of macrobenthos to toxic conditions of surface water, the susceptibility of invertebrate species of different taxonomical groups (Oligochaeta, Diptera, Hirundinea, Isopoda, Gastropoda, Tricladida, Hydrozoa, Heteroptera, Amphipoda, Odonata, Trichoptera, Ephemeroptera, Plecoptera) to 15 chemical compounds and to a mixture of organics concentrated from river Rhine water was determined in acute toxicity tests. The tolerance of macroinvertebrate species are pollutant-specific, whereas the differences in their susceptibility to toxic conditions due to pollution by several toxicants may be negligibly small. Therefore, the reliability of using biological systems based on the macrobenthos distribution to classify surface waters polluted with a variety of chemical pollutants should be seriously doubted. (Murphy-IVI)

THE EFFECT OF TWO TRIAZINE HERBICIDES ON THE PRODUCTIVITY OF FRESHWATER MARSH PERIPHYTON,
Manitoba Univ., Winnipeg. Dept. of Botany.
L. G. Goldsborough, and G. G. C. Robinson.
Aquatic Toxicology, Vol. 4, No. 2, p 95-112, September, 1983. 6 Fig, 4 Tab, 37 Ref.

Descriptors: *Ecological effects, *Triazines, *Herbicides, *Periphyton, Marsh plants, Environmental impact statement, Aquatic productivity, Simazine, Terbutryn.

Simazine has been widely used in lake management and fish culture for the control of undesirable macrophytic species and nuisance phytoplankton blooms. Terbutryn has recently been demonstrated to possess stronger algicidal properties than similar levels of other triazines. The colonization of acrylic substrata by periphyton is monitored by measuring chlorophyll a accumulation and carbon assimilation rate, with varying concentrations of the aquatic herbicides simazine and terbutryn added to in-situ enclosures of marsh water. There was no change, relative to an untreated control, at 0.1 mg/l simazine, with increasing inhibition (to approximately 95%) at 1.0 and 5.0 mg/l. Chlorophyll a and carbon assimilation reduced >90% with terbutryn concentrations of 0.01 ml/l and higher. With factor analysis periphytic productivity correlated with water chemistry, light availability, time and the experimental herbicide treatment. This suggests that herbicidal effects result from a complex interaction of several parameters rather than herbicide concentration alone. Recovery of the communities following decreased herbicide concentrations began within 1 wk, with growth rate equal to or greater than the control. The longterm impact of a single dosage of these herbicides on a periphyton community may be minimal. (Murphy-IVI)

THE MICROTOX* AS AN ALTERNATIVE ASSAY IN THE ACUTE TOXICITY ASSESSMENT OF WATER POLLUTANTS,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
D. De Zwart, and W. Slooff.
Aquatic Toxicology, Vol. 4, No. 2, p 129-138, September, 1983. 4 Fig, 2 Tab, 11 Ref.

Descriptors: *Beckman Microtox Assay System, *Bioassay, *Toxicity, *Pollutants, Comparison studies, Water quality control, Bioluminescence, Bacteria, Algae, Protozoans, Crustaceans, Insects, Coelenterates, Mollusks, Fishes, Amphibians.

The Beckman Microtox Assay System (MAS) is based on the production of light per unit time by living luminescent bacteria, which is a reflection of the rate at which a complex set of energy-producing reactions is operating. Standard toxicity tests usually require 48 to 96 h of testing, and take about 10 h of actual work including the troublesome task of breeding test organisms. The MAS produces representative data in about 0.5 h, which can be considered as a primary test to quickly determine which compounds yield certain risks for the aquatic environment. In this way the standard bioassays could be limited to those samples which warrant further analysis. Mean deviation from the mean of two duplicate tests on each of three different chemicals is found to be about 10%. For some compounds the 15-min EC values were > 10% higher than the corresponding 5-min values. The MAS yielded fairly replicable results which were

comparable wih those obtained with the standard tests. As the MAS does not require the culturing of test organisms and takes about 5% of the actual work involved in the standard procedures, the MAS should be used as a prescreening tool in the hazard assessment of chemicals. (Murphy-IVI)

MONITORING THE RIVERS RHINE AND MEUSE IN THE NETHERLANDS FOR TOXICITY,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
W. Slooff, D. De Zwart, and J. F. J. Van De Kerkhoff.
Aquatic Toxicology, Vol. 4, No. 2, p 189-198, September, 1983. 3 Fig, 2 Tab, 27 Ref.

Descriptors: *Monitoring, *Rhine River, *Meuse River, *Netherlands, *Toxicity, Organic compounds, Bioindicators, Water quality control, Mutagenicity, Surface water.

In the rivers Rhine and Meuse hundreds of potentially hazardous chemical compounds have been identified, usually at low conentrations. Although their presence has been related to chronic effects in fish in both controlled laboratory experiments and field studies, such investigations are too time-consuming to be applicable in routine monitoring programs. Therefore, short-cut biological methods are needed for water quality control, complimentary to chemical monitoring techniques. Samples concentrated by adsorption on XAD followed by elution with acetone, proved to be at least as effective in concentrating organic toxicants from river water as liquid-liquid extraction or freeze-drying. Generally, Rhine water samples were more toxic than those of Meuse water. On one Rhine location on a weekly basis, toxicity was found to vary with the seasons by more than a factor of 12. It is best to incorporate such toxicity screening tests next to chemical analyses in surveillance programs of water quality. Additionally, the biological significance of the mutagenic activity previously observed in Rhine water concentrates in a 6-month test on P. reticulata, had no effects at concentration factors < or = to 10. There were partial effects in a 33 times greater concentration (impaired swimming performance, hypertrophy of the liver, mortality). At concentration factors > or = to 100 mortality occurred rapidly. there were no apparent tumors. The hazard resulting from the chemicals responsible for the mutagenic activity is not the production of cancers, but, if real, the reduction of the fitness of the exposed populations as a result of an increased genetic load. (Murphy-IVI)

SUBLETHAL EFFECTS OF TREATED LIQUID EFFLUENT FROM A PETROLEUM REFINERY. III. AVOIDANCE AND OTHER LOCOMOTOR RESPONSES OF RAINBOW TROUT,
Department of the Environment, Dartmouth (Nova Scotia).
G. F. Westlake, J. B. Sprague, R. J. Hines, and I. T. Brown.
Aquatic Toxicology, Vol. 4, No. 3, p 235-245, November, 1983. 2 Fig, 3 Tab, 18 Ref.

Descriptors: *Sublethal effects, *Treated water, *Petroleum refinery effluent, *Fish behavior, *Rainbow trout, Petroleum industry, Water quality standards, Effluents.

None of the rainbow trout (Salmo gairdneri) in a chamber with side-by-side flows of clean water and 0, 1, 10, or 30% oil refinery effluent, with a steep gradient between the two flows, had statistically significant avoidance or preference behavior. Similarly, the side of entry of the effluent was not related to any differences in relative activity in the four areas. When 30% effluent was present, the general level of activity in all parts of the chamber appeared to be lower than activities for the other concentrations, but the difference was at the borderline of statistical significance (P=0.06). Behavioral response to the effluent was less important than direct physiological effects on trout previously documented with the same effluent. The batches of effluent had an overall 3-day LC50 of about 100% effluent. The effluent exceeded Canadian regulations in average level of ammonia, was somewhat elevated in oil-plus-grease and residue, but was well below regulatory limits for phenols and sulfides. (Murphy-IVI)

SUBLETHAL EFFECTS OF TREATED LIQUID EFFLUENT FROM A PETROLEUM REFINERY. IV. RESPIRATORY MOVEMENTS AND COUGHING OF RAINBOW TROUT,
Environmental Protection Service, Dartmouth (Nova Scotia).
G. F. Westlake, J. B. Sprague, and I. T. Brown.
Aquatic Toxicology, Vol. 4, No. 4, p 317-325, December, 1983. 2 Fig, 1 Tab, 21 Ref.

Descriptors: *Sublethal effects, *Treated water, *Petroleum refinery effluents, *Fish behavior, *Rainbow trout, Bioindicator, Petroleum industry, Effluents, Bioassay, Toxicity, Respiration, Water quality standards, Monitoring.

There have been many studies of lethal levels of refinery effuent to aquatic organisms, but there is almost no published work that establishes the degree of sublethal toxicity. Without such research, there is no way of predicting whether a regulatory effort is likely to produce 'safe' conditions in receiving water. Rainbow trout increased the frequency of gill irrigation in linear relation to the concentration of treated refinery effluent. Full-strength effluent resulted in a significantly higher frequency than in clean water, but 50% and lower did not, because of variation in response. Coughing rate increased sharply and was less variable. A concentration of 50% effluent caused significantly more coughs than in clean water, while 25% did not. The eight samples of effluent caused little lethality at full strength, and average physicochemical characteristics were near or below Canadian regulatory limits, except for elevated oil and grease. Coughing rate shows promise as a rapid initial method for sublethal screening or monitoring of refinery effluents. (Murphy-IVI)

SUBLETHAL EFFECTS OF TREATED LIQUID EFFLUENT FROM A PETROLEUM REFINERY. V. REPRODUCTION OF DAPHNIA PULEX AND OVERALL EVALUATION,
Environmental Protection Service, Dartmouth (Nova Scotia).
G. F. Westlake, J. B. Sprague, and D. W. Rowe.
Aquatic Toxicology, Vol. 4, No. 4, p 327-339, December, 1983. 3 Fig, 2 Tab, 29 Ref.

Descriptors: *Sublethal effects, *Treated water, *Petroleum refinery effluent, *Population dynamics, *Daphnia, Comparison studies, Evaluation, Population exposure, Bioindicator, Bioassay, Toxicity, Reproduction, Monitoring, Water quality standards, Effluents, Oil refineries.

Despite the worldwide occurrence of oil refineries, and much concern about regulating their discharges into surface waters, there is almost no research on sublethal effects of a real refinery effluent on aquatic organisms. The 48-h LC50 of treated refinery effluent for 2-day-old Daphnia pulex was 76% effluent. The 14-day LC50 was 6.4% effluent and this was a threshold value for mortality. For reproductive failure, the 14-day EC50 was 3.1% effluent, and the EC5 of 0.52% effluent was considered to approximate the threshold of sublethal effect. Daphnia reproduction was the most sensitive response in a series of studies that included fish growth, reproduction, locomotion, and respiration. Results are considered representative for a well-treated effluent from a petroleum refinery. The 48-h lethal test with D. pulex would be a useful tool for monitoring or assessing such effluents, since it is simple, small-scale, quick, and about 2.6 times as sensitive as a lethal test with trout. OVERLAP AND POLLUTION-INDUCED VARIABILITY IN THE FEEDING HABITS OF FILEFISH (PISCES: MONACANTHIDAE) FROM APALACHEE BAY, FLORIDA,
Florida State Univ., Tallahassee. Dept. of Biological Science.
W. H. Clements, and R. J. Livingston.
Copeia, No. 2, p 331-338, May, 1983. 5 Fig, 3 Tab, 40 Ref. EPA grant R-805288010.

Descriptors: *Water pollution effects, *Fish behavior, *Variability, *Filefish, *Apalachee Bay, *Florida, Estuaries, Estuarine fisheries, Spatial distribution, Temporal distribution, Pulp wastes, Ecological effects.

The impact of pollution on feeding habits and trophic structure is not well known. Changes in the distribution and abundance of prey resulting from disturbances will often be refleted in a predator's diet. The spatial and temporal distribution and feeding habits of two species of filefish, Monacanthus ciliatus and Stephanolepis hispidus, overlap broadly. An apparent similarity in diet reduced when prey were identified to species. Ontogenetic variation of each species had a tendency toward herbivory with increasing standard length. The feeding habits of M. ciliatus taken from areas affected by pulp mill effluents were different than those from a nearby unpolluted estuary. Cluster analysis of stations within the two systems, based on feeding habits of M. ciliatus, were similar to those based on numbers of fishes and macrophyte biomass. Differences in the feeding habits between the two systems may be due to pollution-induced habitat modifications and resulting changes in prey distribution. This may represent an additional method of assessing the effects of pollution. (Murphy-IVI)

ECOLOGY OF PLANKTONIC LARVAE OF DREISSENA POLYMORPHA (PALL.) IN LAKES WITH DIFFERENT DEGREE OF HEATING,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
K. Lewandowski, and J. Ejsmont-Karabin.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 2, p 89-101, 1983. 7 Fig, 4 Tab, 28 Ref.

Descriptors: *Ecology, *Larvae, *Dreissena, *Thermal pollution, Epilimnion, Thermal stratification, Powerplants, Cooling water, Thermocline, Mollusks, Mortality, Poland.

The heating of waters in natural water bodies is an effect of the operation of electric power stations which use the water for cooling purposes. The Konin Lakes complex (Poland), heated by Konin and Patnow power stations, is an example of altered ecosystems. The power stations have a problem with mass invasions of Dreissena polymorpha. The planktonic larvae of D. polymorpha were studied during six seasons (1970-1970) in six lakes included in the cooling systems of the electric power stations. They were encountered from April until September, with an earlier appearance by two months in heated lakes than in unheated lakes of the same climatic zone. Most of the larvae (90%) were in the epilimnion of the lakes except for near the discharge of cooling waters to Slesinskie Lake where larvae were abundant in the whole water column. The youngest larvae were most abundant in shallow layers, the older ones in the deeper zone. There were considerable numbers of dead larvae (up to 20 individuals per cu dm) in the studied lakes. There is a high mortality rate due to the heating of the lakes. (Murphy-IVI)

ECOLOGICAL CHARACTERISTICS OF POLI SAPROBIC SECTION OF THE VISTULA RIVER BELOW WARSAW,
Polish Academy of Sciences, Warsaw. Inst. of Ecology.
M. Kaniewska-Prus.
Polskie Archwum Hydrobiologii, Vol. 30, No. 2, p 149-163, 1983. 9 Fig, 3 Tab, 23 Ref.

Descriptors: *Water pollution effects, *Vistula, *Poland, Benthos, Water quality, Seasonal varia

tion, Dissolved oxygen, Nitrogen, Phosphates, Oligochaetes, Diptera, Biomass, Eutrophication, Wastewater pollution.

In 1980-81 studies were carried out on chemical changes in water, and numbers and biomass of macrobenthos in the Vistula river (Poland) at various distances from the pollution source (municipal sewage). From chemical analyses the quality of water was estimated by qualitonomic method. Along a section of 25 km in length from the source of pollution the quality of water does not undergo considerable changes. At all four site the water possessed a high oxygen saturation. The concentration of chlorides was also high at all sites. Inorganic nitrogen and phosphate concentrations were highest at the site nearest the pollution source and lowest at the site farthest from it. The water quality, depending on the season, is either very bad, or bad; only sporadically is it of average level. Among benthic animals Oligochaeta are clearly predominant. Tendipedidae were regularly observed and other dipteran larvae were observed sporadically. Both numbers and biomass of benthos varied considerably depending on the season and water quality. The indices of water pollution, as based on numbers and biomass of taxonomic groups of benthic animals have corroborated the high degree of pollution in this section of the river. (Moore-IVI)
W84-03154

OXYGEN CONSUMPTION AND SURVIVAL OF ASELLUS AQUATICUS L. (CRUSTACEA) IN VISTULA RIVER SECTION HIGHLY POLLUTED BY MUNICIPAL SEWAGE,
Polish Academy of Sciences, Warsaw. Inst. of Ecology.
D. Zimakowska-Gnoinska.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 2, p 165-173, 1983. 4 Fig, 1 Tab, 15 Ref.

Descriptors: *Water pollution effects, *Asellus, *Vistula, *Poland, Municipal wastewater, Wastewater pollution, Oxygen consumption, Mortality, Crustaceans, Respiratory rate.

The impact of polluted water was determined on oxygen consumption and survival of males of Asellus aquatticus L. in the period March-November 1981. The water was collected from foursites on the Vistula river, in the 25 km section from Bielany sewage collector output to Dziekanow Polski, which is polluted by Warsaw (Poland) municipal sewage. Measurements of respiratory rate were carried out in volumetric respirometers directly after placing animals in the polluted water, and after 24 hr of exposure to the water. Vistula river water has an unfavorable and irreversible effect on A. aquaticus causing augmented respiration and delayed mortality. Experimental animals after exposure to this water for 3 or 24 hours were transferred to a pure environment. Higher mortality was observed in the next 8 months. The differences from the controls were greatest in the group of animals which had been exposed to the most polluted water. (Moore-IVI)
W84-03155

THE COREGONES OF LAKE NEUCHATEL: FISHERY YIELD; AGE AND GROWTH OF INDIVIDUALS CAUGHT BY PROFESSIONAL FISHERMEN (LES COREGONES DU LAC DE NEUCHATEL: RENDEMENT DE LA PECHE; AGE ET CROISSANCE DES INDIVIDUS CAPTURES PAR LES PECHEURS PROFESSIONNELS),
Inspection Cantonale de la Chasse et de la Peche, Neuchatel (Switzerland).
J. C. Pedroli.
Schweizerische Zeitschrift fur Hydrologie, Vol. 45, No. 1, p 345-358, 1983. 5 Fig, 1 Tab, 10 Ref, 1 Append.

Descriptors: *Eutrophication, *Coregonus, *Lake Neuchatel, *Switzerland, Growth, Lake fisheries, Commercial fishing, Fish populations.

The fishery of the indigenous Coregonus sp. (whitefish) of Lake Neuchatel (Switzerland) was studied using statistics kept since 1917 and data on length, weight, and age for fish caught at random in 1927-30, 1947/48, and 1978-80. Although the total numbers and weight of C. fera (a fast growing species) are more or less constant, those of C. macrophthalmus (a slow growing species) have diminished by 75%. Compared to other large lakes in Switzerland, the whitefish catch in Lake Neuchatel has been abnormally low for the last 20 yr. A decrease in the number of whitefish and eutrophication of the lake are two factors which have lowered the mean age of the fish and accelerated their growth rate. For 1978-80, the lengths of the fish are more uniform, and the two types are more difficult to distinguish. This may be due to hybridization, but it is more likely that the frequency of lengths per age class are more uniform. (Moore-IVI)
W84-03176

DECLINE OF RED SPRUCE IN THE NORTHERN APPALACHIANS: ASSESSING THE POSSIBLE ROLE OF ACID DEPOSITION,
Pennsylvania Univ., Philadelphia.
A. H. Johnson, and T. G. Siccama.
Tappi Journal, Vol. 67, No. 1, p 68-72, January, 1984. 6 Fig, 31 Ref.

Descriptors: *Spruce, *Acid deposition, *Acid rain, *Appalachian Mountains, Forests, Clouds, Acid mists, Heavy metals, Aluminum, Metals, Plant pathology, Drought, High elevations, Water pollution effects.

High-elevation spruce-fir forests of the eastern U.S. receive particularly high rates of acidic deposition (up to 4 keq of H(+)/ha/yr), vegetation is exposed to highly acidic cloud moisture for up to 2000 h/yr, and very high levels of trace metals have accumulated. Red spruce (Picea rubens) in the northern Appalachians have died in abnormally large numbers over the past two decades without obvious cause. Considerable attention has been focused on the possible role of acid deposition in the decline. Because of the documented accumulation of heavy metals, the high rates of acidic deposition, the prolonged contact with acidic mist, and laboratory evidence that reasonable levels of dissolved aluminum and possibly other metals can alter water movement in red spruce, anthropogenic pollutants may be involved in the red spruce decline. Widespread reports of spruce mortality in the last century following a series of dry summers suggest the possibility that spruce decline could occur in the absence of high levels of acid or metal deposition. (Moore-IVI)

GROWTH OF SALVINIA MOLESTA AS AFFECTED BY WATER TEMPERATURE AND NUTRITION; II. EFFECTS OF PHOSPHORUS LEVEL,
Commonwealth Scientific and Industrial Research Organization, Griffith (Australia). Div. of Irrigation Research.
P. R. Cary, and P. G. J. Weerts.
Aquatic Botany, Vol. 17, No. 1, p 61-70, September, 1983. 4 Tab, 9 Ref.

Descriptors: *Salvinia, *Aquatic weeds, *Temperature effects, *Phosphorus, *Nutrient removal, Nutrients, Water temperature, Growth, Biological treatment.

Salvinia molesta is a free-floating aquatic plant that is native to South America, but is now widely distributed throughout the tropics. The growth of S. molesta, as affected by phosphorus supply and water temperature, was studied in a greenhouse using controlled water temperature baths at 16, 19 and 22 C. For significant responses to the phosphorus treatments to be obtained it was necessary to use P-deficient plant propagules (containing < 0.01% P on a dry matter basis). For these plants the highest relative growth rate and dry matter production occurred at 22 C when they received 10.01 mg PO4-P/l, but this was not significantly different from that of plants receiving 1.01 mg PO4-P/l. Over a period of 21 days for plants receiving 0.02 mg PO4-P/l the biomass increased 4-fold at 19 C and 6-fold at 22 C. In contrast, for plants receiving 10.01 mg PO4-P/l biomass was increased 20-fold at 19 C and 32-fold at 22 C. At the latter temperature, when receiving 60.06 mg PO4-P/l, plants concentrated up to 1.3% of phosphorus on a dry matter basis, suggesting a possible use as a biological filter and purifier of contaminated waters. Water authorities should maintain nutrients below minimum critical levels to prevent explosive growth of this notorious weed. (Moore-IVI)

A STUDY ON THE GROWTH OF SALVINIA MOLESTA MITCHELL IN RELATION TO LIGHT AND TEMPERATURE,
Kurukshetra Univ. (India). Dept. of Botany.
V. Usha Rani, and S. Bhambie.
Aquatic Botany, Vol. 17, No. 2, p 119-124, October, 1983. 2 Fig, 1 Tab, 12 Ref.

Descriptors: *Aquatic weeds, *Salvinia, *Solar radiation, *Temperature effects, *Growth, Seasonal variation, Water quality.

Salvinia molesta is a free-floating weed in most of the Indian inland freshwater systems. It adversely affects water quality, decreases aesthetic values and creates problems for rice growers. The effects of light intensity and temperature on the growth of S. molesta were studied under shade and full sunlight conditions. Growth, in terms of increase in fresh weight and number of offshoots produced was significantly different ($P<0.001$) under the two light conditions; it was highest under shade during May-July, and in August-September under full sunlight. From November to March, under both light conditions, growth was reduced and was minimal from December to February in shade and from December to January in full sunlight. Mean relative growth rate (RGR) varied from 0.01 to 0.07 g/g/day. Increase in the fresh weight had a significant positive non-linear relationship with light intensity and atmospheric temperature. However, since there was a significant positive relationship between temperature and light intensity, it was not possible to separate their effects through regression analysis. (Moore-IVI)

CHARR AS INDICATORS OF POLLUTION,
Staatliches Inst. fuer Seenforschung und Fischereiwesen, Langenargen (Germany, F.R.).
J. Hartmann.
Fisheries, Vol. 8, No. 6, p 10-12, November-December, 1983. 1 Fig, 19 Ref.

Descriptors: *Charr, *Bioindicators, *Pollutant identification, Lake Constance, Eutrophication, Hydrocarbons, Heavy metals, Chironomids, Turbellarians, Tubificids.

Lake Constance forms a border between Austria, Switzerland, and West Germany. The lake has been subject to eutrophication in recent decades. Chironomids and turbellarians are two of the three main components of the charr's diet in the lake and these organisms may also be useful as biological indicators. The horizontal distribution of the charr in Lake Constance before and after cultural eutrophication is quite different. Areas where charr are still caught in large numbers today support few tubificids but many chironomids. These habitats are distant from the major towns and sites of affluent waters and sediments and are not severely polluted by hydrocarbons or heavy metals. The distribution of the charr has progressively been constrained to the least disturbed areas of the lake. (Murphy-IVI)

THE MACROINVERTEBRATE FAUNA OF THE DRAINAGE CHANNELS OF THE GWENT LEVELS, SOUTH WALES,
University of Wales Inst. of Science and Technology, Cardiff. Dept. of Applied Biology.
P. Clare, and R. W. Edwards.
Freshwater Biology, Vol. 13, No. 3, p 205-225, June, 1983. 7 Fig, 10 Tab, 42 Ref.

Descriptors: *Macroinvertibrates, *Drainage channels, *Gwent Levels, *South Wales, Benthic fauna, Oxygen balance.

From a survey of the fauna at sixty sites in permanent drainage channels of the Gwent Levels during the spring of 1976 and at some of these sites (thirty-three) during the autumn, species and site associations were identified using classification and ordination techniques. Sites in some groups had identifiably similar environmental characteristics and grouping seemed particularly related to the vegetational stage in the hydrosere, water flow and the incidence of salt contamination from the Severn Estuary. Characteristics which were common within particular species groups and which, in part, explained their distributions were: adaptation to low oxygen concentrations, food preferences and dispersal mechanisms. Whilst there was some temporal stability in site groups between the spring and autumn surveys, such associations were not identical. The oxygen status of channels appeared a major factor determining faunal distribution. Twelve sites, representing a range of channel types, were sampled six times in a 12-month period. Far more species were collected within the water column and on plants than in the benthos. Several oligochaetes, e.g. Aulodrilus pluriseta, Dero digitata, Limnodrilus claparedeanus, were not recorded at most sites during the summer probably because of the sustained lack of oxygen at these sites. Three contiguous reaches of channel were maintained during the period March-October 1977 with different plant cover (no Lemna; complete Lemna cover; control with partial Lemna cover). The oxygen status of the reaches was different, that with complete Lemna cover being continuously anaerobic near the channel bed for several months, the control reach which had partial Lemna cover being anaerobic for a shorter period and that with no Lemna being only anaerobic at night. Whilst the distribution of macroinvertebrate species was principally related to this oxygen status, the control reach which was structurally the most complex, having both submerged and floating plants, contained about twice as many species as the other reaches during the summer (collected in the water column and on plants): benthic samples in this and the reach with complete Lemna cover contained only between zero and two species during the period May-September. A MODEL RELATING THE RESULTS OF LOW PH BIOASSAY EXPERIMENTS TO THE FISHERY STATUS OF NORWEGIAN LAKES,
Central Electricity Generating Board, Ratcliffe-on-Soar (England). Ratcliffe-on-Soar Power Station.
K. Sadler.
Freshwater Biology, Vol. 13, No. 5, p 453-463, October, 1983. 5 Fig, 2 Tab, 51 Ref.

Descriptors: *Model studies, *Hydrogen ion concentration, *Bioassay, *Fisheries, *Lakes, *Norway, Water pollution sources, Fate of pollutants, Water quality, Water pollution effects, Trout, Mortality, England.

The acidification of waters has been linked with the loss of fish populations. One of the best studied regions which has been the subject of much concern is Sorlandet (southernmost Norway). Leslie matrices using data from the literature concerning serveral Norwegian brown trout (Salmo trutta) populations estimates their capacity to withstand egg and fry mortalities. These estimates compared with the results of bioassay studies conducted at pH 4.5 and at various calcium concentrations predicts the percentage of trout populations which would be able to survive these conditions. These predictions are in good agreement with the observed fishery status of Norwegian lakes at calcium concentrations <30 microeq/l but above this concentration the recorded status is worse than predicted. Likely causes for this difference are considered to be effects acting on fish older than those used in the bioassay experiments (either mortality or reduction in fecundity possibly due to impaired growth) or the effects of other water quality factors, for example aluminium. These effects need only be fairly slow acting as compared with the egg and fry mortalities so far studied in detail. Thus the discrepancy between predicted and observed results at pH 4.5 and 50 microeq/l calcium could be caused by an additional 80% mortality acting over the 4-8 year period before maturation. An additional factor which could result in the observed fishery status being worse than predicted is temporal variation in water chemistry which is not assessed in the survey of Norwegian lakes. In particular, the adverse conditions occurring at time of snowmelt could be critically important. (Murphy-IVI)

PRIMARY PRODUCTIVITY STUDIES DURING EARLY YEARS OF WEST POINT RESERVOIR, ALABAMA-GEORGIA,
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
D. R. Bayne, J. M. Lawrence, and J. A. McGuire.
Freshwater Biology, Vol. 13, No. 5, p 477-489, October, 1983. 4 Fig, 3 Tab, 36 Ref.

Descriptors: *Primary productivity, *West Point Reservoir, *Alabama, *Georgia, Phytoplankton, Fish populations, Population dynamics, Eutrophication, Hydrogen ion concentration, Water quality, Water pollution effects, Water pollution sources, Fate of pollutants.

Phytoplankton density (organisms/ml), standing crop (chlorophyll a mg/sq m) and primary productivity (mg C/m/d) were measured during years 2 (1976) to 5 (1979) after impoundment on West Point Lake. West Point waters had low alkalinity (<0.4 meq/l) and low conductivity (< 75 micros/cm at 20 degrees C) but N and P concentrations typically exceeded those considered apt to cause nuisance blooms of algae. Abiogenic turbidity was normally higher in the upstream areas of the reservoir than in the downstream areas and was several times higher in winter-spring than in summer-autumn due to increased rains and runoff. Primary productivity varied greatly both temporally and spatially. A mean value of 684 mg C/m/d was well within the mesotrophic range and did not approach the highly eutrophic state predicted. Productivity increased from a low of 550 mg C/m/d in 1976 to high of 763 mg C/m/d in 1979. Observed variation in both chlorophyll a and primary productivity was more predictable in the cool (December-March) than in the warm (June-September) season and with plant nutrient data than without it. With plant nutrient data in the cool season 84% and 86% of the variation (R2) in chlorophyll a and productivity, respectively, were accounted for by the regression equations. During the warm season, with plant nutrient data, regression equations accounted for 44% and 68% of the variation in chlorophyll a and productivity, respectively. Higher R2 values in cool seasons resulted from the overriding influence of abiogenic turbidity on phytoplankton communities. (Author's abstract)

COMMUNITY STRUCTURE IN SOME SOUTHERN ENGLISH STREAMS: THE INFLUENCE OF PHYSICOCHEMICAL FACTORS,
University of East Anglia, Norwich (England). School of Biological Sciences.
C. R. Townsend, A. G. Hildrew, and J. Francis.
Freshwater Biology, Vol. 13, No. 6, p 521-544, December, 1983. 8 Fig, 3 Tab, 57 Ref.

Descriptors: *Community development, *England, *Streams, *Physiochemical properties, Hydrogen ion concentration, Water pollution effects, Water pollution sources, Biological properties, Population dynamics, Aquatic fauna.

Low pH and high iron concentration are factors of growing concern to aquatic ecologists. Acidification of surface waters by polluted rainfall is widespread and acute and acid waters always seem impoverished in comparison with systems which are more basic but otherwise similar. Invertebrates and fish were surveyed during October 1976 in thirty-four stony riffle stream sites in Ashdown Forest, Sussex. A variety of physicochemical factors were also measured in an attempt to assess the importance of each in determining the distribution of species and the structure of communities. Three analytical techniques - stepwise multiple regression analysis, ordination and community classification - revealed that the structure of these communities was strongly related to variation in stream pH. Acid sites had low numbers of individuals, low species richness and low equitabilities. Summer temperature and stream discharge also appeared to play significant roles. The pattern of catchment land use has an important bearing on stream pH. In the most acid sites only collectors, shredders and predators occurred. In more basic sites the number of species in collector and predator categories increased and these were joined by grazer/scrapers and filter feeders. A theoretical basis for explaining stream community structure is discussed. (Murphy-IVI)

CONCENTRATIONS OF TOTAL DISSOLVED SOLIDS PREFERRED OR AVOIDED BY ENDANGERED COLORADO RIVER FISHES,
Utah Cooperative Fishery Research Unit, Logan.
R. Pimentel, and R. V. Bulkley.
Transactions of the American Fisheries Society Vol. 112, No. 5, p 595-600, September, 1983. 1 Fig, 3 Tab, 20 Ref.

Descriptors: *Concentrations, *Total dissolved solids, *Fish behavior, *Endangered species, *Colorado River, Dissolved solids, Environmental effects, Squawfish, Humpback chub, Bonytail, Water pollution effects.

Juveniles of three endangered Colorado River fishes were subjected to a gradient of total dissolved solids (TDS) to determine the concentrations that they preferred or avoided. Preferred and avoided TDS concentrations, respectively, for juveniles of Colorado squawfish were 560-1,150 mg/l and greater than 4,400 mg/l, for humpback chub 1,000-2,500 mg/l and greater than 5,100 mg/l, and for bonytail 4,100-4,700 mg/l and less than 560 mg/l or greater than 6,600 mg/l. Colorado squawfish and humpback chubs selected TDS concentrations that were similar to those in waters they now inhabit, but bonytails selected concentrations four times higher. Future increases of TDS in the Colorado River system would degrade municipal, industrial, and agricultural water used before these endangered fishes would be affected. (Murphy-IVI)

TEMPERATURE PREFERENCE AND AVOIDANCE BY ADULT RAZORBACK SUCKERS,
Utah Cooperative Fishery Research Unit, Logan.
R. V. Bulkley, and R. Pimentel.
Transactions of the American Fisheries Society Vol. 112, No. 5, p 601-607, September, 1983. 1 Fig, 2 Tab, 36 Ref.

Descriptors: *Temperature, *Fish behavior, *Suckers, Temperature effects, behavior, Colorado River, Fish conservation, Fish management, Environmental effects, Dam effects.

Final thermal preferendum for the razorback sucker (Xyrauchen texanus), a rare endemic species of the Colorado River basin, was between 22 and 24.8 C based on electronic-shuttlebox studies. Upper and lower avoidance temperature ranges from 27.4 to 31.6 C and from 8.0 to 14.7 C

espectively. Lower, but not upper, avoidance emperature was positively correlated with accli- ation temperature. The lower aviodance temper- ture and thermal preferenda support the theory at temperature change was involved in the disap- earance of razorback suckers and three other ative endangered species form the tailwaters of laming Gorge Reservoir on the Green River, Jtah. New water-control structures on the upper Colorado River drainage should be designed to rovide summer water temperatures between 22 nd 25 C if preservation of habitat for this species a consideration. ALTERATIONS IN GILL EPITHELIAL MORPHOLOGY OF YEARLING SUNAPEE TROUT EXPOSED TO ACUTE ACID STRESS,
Maine Cooperative Wildlife Research Unit, Orono.
C. H. Jagoe, and T. A. Haines.
Transactions of the American Fisheries Society, Vol. 112, No. 5, p 689-695, September, 1983. 3 Fig, 2 Tab, 36 Ref.

Descriptors: *Fish, *Acidity, *Water pollution effects, Trout, Acid rain, Mortality, Maine, Hydrogen ion concentration.

Gill filaments of hatchery-reared yearling Sunapee trout Salvelinus alpinus oquassa that had been exposed to acute acid stress in static water bioassays were examined by scanning electron microscopy. Fish exposed to acidified water at pH levels above those that caused acute mortality showed little alteration in gill morphology. Exposure to acutely lethal levels of acidity caused considerable damage to gill epithelia, including primary lamellar swelling, increasingly rugose secondary lamellar surfaces, increased mucus production, and fusion of adjacent secondary lamellae. The loss of microridge patterns on the epithelia of the secondary lamellae became more severe with decreasing pH. Such changes may decrease the surface area avaiable for gas exchange and contribute to the anoxia that appears to be an important source of mortality in very low pH levels. (Baker-IVI)

ACUTE TOXCITY OF AMMONIA TO RAINBOW TROUT,
Montana State Univ., Bozeman. Fisheries Bioassay Lab.
R. V. Thurston, and R. C. Russo.
Transactions of the American Fisheries Society, Vol. 112, No. 5, p 696-704, September, 1983. 1 Fig, 5 Tab, 15 Ref. EPA grants R800861, R803950 and CR807240.

Descriptors: *Ammonia, *Trout, Fish, Toxicity, Water pollution effects, Acclimatization, Dissolved oxygen.

The acute toxicity of ammonia to hatchery-reared rainbow trout was measured in 86 flow-through tests, ranging from 96 hours to 35 days in length. Fish ranged in age from 1 day old fry to 4 yr old adults. The 96 hour median lethal concentrations ranged from 0.16 to 1.1 mg/liter unionized ammonia. Susceptibility to ammonia decreased as the fish developed from sac fry to juveniles, and increased thereafter. Acute toxicity decreased as temperature increased over the range 12 to 19 degrees C. No significant differences in toxicity were observed in tests with different ammonium salts including ammonium chloride, ammonium bicarbonate, ammonium phosphate and ammonium sulfate. The LC50 values obtained for 12- and 35-day tests were not appreciably different from those obtained for tests of shorter time periods. (Baker-IVI)

CHRONIC EFFECTS OF COAL-LIQUID DISPERSIONS ON FATHEAD MINNOWS AND RAINBOW TROUT,
Battelle Pacific Northwest Labs., Richland, WA. Environmental Sciences Dept.
D. D. Dauble, S. A. Barraclough, R. M. Bean, and W. E. Fallon.
Transactions of the American Fisheries Society, Vol. 112, No. 5, p 712-719, September, 1983. 1 Fig, 3 Tab, 16 Ref. USDE contract DEAC06-76RLO 1830.

Descriptors: *Fish, *Water pollution effects, *Phenols, Coal-liquification, Trout, Minnows, Mortality, Toxicity, Organic compounds, Bioassay.

Fathead minnows and rainbow trout were used in partial-life-cycle bioassays under continuous-flow regimes, with water soluble fractions (WSFs) derived from a coal liquid. Phenols constituted 95% of the organic carbon in stock WSFs. Growth of larval fathead minnows was significantly reduced at 0.25 mg/liter total phenols as determind by dye photometry. At 1.27 mg/liter total phenols, spawning of adult fathead minnows was inhibited and was significantly reduced at 0.62 mg/liter total phenols. Spawning inhibition was not permanent at these concentrations. Fathead minnow pairs resumed spawning 21 days after transfer to control water. The minimal concentration of WSFs that caused significant mortality to rainbow trout depended on the length of time exposed. A 14 day exposure to concentrations equal to or greater than 2.98 mg/liter total phenols was fatal to all rainbow trout embryos due to either egg mortality or premature hatching. Rapid mortality was noted in swim-up rainbow trout after 28 days exposure to 0.13 mg/liter total phenols. Death was partially attributed to clogging of the gills by fungal growth. Possible changes in the composition of water-soluble components occur due to chemical and biological degradation, making long term toxic effects of complex organic mixtures difficult to predict based on dilution of known constituents. PHENOL TOLERANCE IN POPULATIONS OF MOSQUITOFISH FROM POLLUTED AND NONPOLLUTED WATERS,
Alabama Univ. in Birmingham. Dept. of Biology.
R. A. Angus.
Transactions of the American Fisheries Society, Vol. 112, No. 6, p 794-799, November, 1983. 2 Tab, 7 Ref.

Descriptors: *Fish behavior, *Phenols, *Water pollution effects, Organic compounds, Mosquitofish, Fish, Mortality, Industrial wastes, Lake Purdy, Valley Creek, Alabama.

Fish populations in polluted streams, if not driven to local extinction, may adapt to certain toxic substances over time. Adaptation may involve physiological acclimation if previous exposure has led to the induction of detoxification enzyme systems. The phenol tolerances of three Alabama populations of mosquitofish were compared. Two of the populations lived in industrially polluted streams and one in a nonpolluted lake. The 48 hour phenol LC50 was significantly higher for mosquitofish from Valley Creek, below the point where the creek receives coke-treatment wastewater from a steel plant, than for populations from Village Creek or the unpolluted Lake Purdy. The 8-hour tests confirmed the existence of resistant and susceptible phenotypes in the Valley Creek and Lake Purdy populations. Both populations contained fish of resistant and susceptible phenotypes. The difference was in their relative frequencies. In Valley Creek, 67-80% of the fish were resistant whereas in Lake Purdy, only 23-27% of the fish were resistant. An 8-hour toxicity test with 1 mg/liter potassium cyanide showed no discrete categories of susceptible or resistant fish. Mortality occurred throughout the test and a majority of fish died in the middle 4 hours. (Baker-IVI)

WATERBORNE DISEASE OUTBREAKS - 1946-1980: A THIRTY-FIVE-YEAR PERSPECTIVE,
Breidenbach Environmental Research Center, Cincinnati, OH.
E. C. Lippy, and S. C. Waltrip.
Journal American Water Works Association, p 60-67, February, 1984. 16 Fig, 5 Tab, 8 Ref.

Descriptors: *Human diseases, Disinfection, Water supply, Water quality control, Microorganisms, Public health, Pathogenesis.

The 672 outbreaks of waterborne disease that were reported in the United States between 1946 and 1980 affected more than 150,000 persons. An analysis of the data from these oubreaks provides information on how often and where they occurred, as well as on what caused them. Using just the data from 1976-1980, when reporting was greatly improved, the average annual frequency of outbreaks was 38. Clustering was evident when outbreaks in community systems were geographically distributed and rate-based according to the number of water systems in a respective state. Outbreaks exhibit temporal distribution, with peak occurrences in June, July, and August. Although outbreaks in noncommunity systems outnumber those in community systems, the frequency of outbreaks is almost twice as great in community systems. Cases of illness occurring in community water systems far outnumber those in noncommunity systems. Regulatory agencies should concentrate their efforts on protecting the source of water supply. Microbial agents that cause waterborne outbreaks are rarely isolated from the water system. The deficiences in water systems that caused and contributed to waterborne outbreaks during this 35 year period differed little from those reported for the previous 26 years. The glaring deficiencies were that disinfection was not in place where it was needed and not properly operated where it was in place. (Baker-IVI)

THE INFLUENCES OF TEMPERATURE VARIATIONS AND THERMAL POLLUTION ON VARIOUS ASPECTS OF THE BIOLOGY OF THE PRAWN PALAEMON PACIFICUS (STIMPSON),
Cape Town Univ. (South Africa). Dept. of Zoology.
Y. Achituv, and P. A. Cook.
Journal of Experimental Marine Biology and Ecology, Vol. 74, No. 3, p 291-302, January, 1984. 3 Fig, 8 Tab, 15 Ref.

Descriptors: *Temperature effects, *Thermal pollution, *Prawn, *Palaemon pacificus, *Stimpson, Thermal stress, Growth, Growth kinetics, Juvenile growth stage, Growth stages, Fish behavior.

The influence of different temperatures 10, 15, 20, and 25 degrees Centigrade on the food consumption, growth, moulting rate, and respiration of Palaemon pacificus (Stimpson) from Langebaan Lagoon, west coast of South Africa, under laboratory conditions, produced a high mortality rate at 10 degrees C. At higher temperatures, food consumption was found to be temperature dependent, the rate at 25 degrees C being twice that at 15 degrees C. Growth rate was most favorable at 25 degrees C. At 28 degrees C growth rate was lower than at 20 degrees C but higher than at 15 degrees C. The intermoult period was 17 days at 15 degrees C, and 11 and 10 days at 20, and 25 degrees C, respectively. There are several indices of growth efficiency at different temperatures. Its temperature preferences cause the appearance of this prawn in South African west coast localities such as Langebaan during the summer and its disappearance during winter. It is possible that thermal pollution from a nuclear power station may be beneficial to this prawn. (Murphy-IVI)

ACID RAIN, CATCHMENT CHARACTERISTICS AND FISHERY STATUS,
Central Electricity Generating Board, Leatherhead (England). Central Electricity Research Labs.
P. F. Chester.
Water Science and Technology, Vol. 15, No. 12, p 47-58, 1983. 8 Fig, 13 Ref.

Descriptors: *Acid rain, *Catchment areas, *Fisheries, Effective reactivity, Prediction, Oligotrophic lakes, Chemical properties.

Data on lake chemistry and fishery status in the Sorlandet area of South Norway are examined for relationships between acid inputs, water composition and fishery status. The effective catchment reactivity is a much better predictor of fishery status than is acid input to these catchments. An analysis of the only extensive published data set relating water chemistry to fishery status in oligotrophic acid lakes does not support the simple thesis that acid deposition has affected fishery status unless it is assumed that soil minerals or catchment characteristics have been altered substantially by acid deposition. To account for the reported changes in barrenness over the last 30-40 years, the effective reactivity or neutralizing capability of the most affected catchments will have to decrease by a factor of two. It is unlikely that this happened so rapidly through depletion or exhaustion of base cations. Observation of catchment reactivity as revealed by simple measurements of lake water chemistry over a period of a few years determine whether changes of the required magnitude are occurring in the catchments. A proper understanding of the reactivities and biological activity of the catchments and their evolution with time is crucial for the specification of effective measures to counter the decline in fisheries. (Murphy-IVI)

FISHERY STATUS AND WATER QUALITY IN AREAS AFFECTED BY ACID DEPOSITION,
Central Electricity Generating Board, Leatherhead (England). Central Electricity Research Labs.
G. D. Howells.
Water Science and Technology, Vol. 15, No. 12, p 67-80, 1983. 9 Fig, 3 Tab, 25 Ref.

Descriptors: *Fish populations, *Water quality, *Acidity, Oligotrophic lakes, Fish, Mortality, Hydrogen ion concentration.

A review of current information from both field and laboratory investigations concerning the responses of fish and fish populations to natural acid conditions in Scandinavian and North American lakes and rivers, identifies the factors which determine survival and mortality. It is generally recognized that fisheries do not thrive in acid waters below pH 5. Fifty-percent of lakes below pH 5 are fishless, compared with only one in seven of similar oligotrophic lakes with pH greater than 5. Both field and laboratory studies provide evidence that other water quality factors (such as the levels of aluminium and calcium), biological factors (such as food supply, genetically determined tolerance, adaptation), and ecological factors (such as lake morphology, patterns of hydrological events) are also important. (Murphy-IVI)

RELIABILITY OF RIVER-TREATMENT PLANT SYSTEMS,
Ohio State Univ., Columbus.
R. M. Sykes.
Journal of Environmental Engineering, Vol. 110, No. 1, p 166-173, February, 1984. 1 Fig, 2 Tab, 7 Ref.

Descriptors: *Water pollution sources, *Wastewater treatment, *Pollution load, *River flow, Drought, Low flow, Flow rate, Effluents, Water quality standards.

The reliability of river - treatment plant systems is determined by considering fluctuations in both the streamflow rate and waste loading rate. The method involves an application of the elementary theory of hydrologic statistics and waste assimilation models to the cumulative density functions of the flow rates and loading rates. The products of the method are the expected number of system failures per drought, the interval between failures and the annual return period of droughts containing at least one systems failure. It is shown that the usual methods based on rare drought flows, (e.g., the seven-day average flow with a 10-yr return period) cannot provide this information. Also, designs based on rare drought flows are not conformable to stream standards, whereas designs based on the proposed method are intrinsically conformable to stream standards. (Author's abstract)

THE INFLUENCE OF THE GRAND RIVER ON PHYTOPLANKTON NEAR THE NORTHEASTERN SHORE OF LAKE ERIE DURING 1979,
Ontario Ministry of the Environment, Rexdale. Limnology and Taxonomy Section.
K. H. Nicholls, R. Taylor, and Y. Hamdy.
Archiv fur Hydrobiologie, Vol. 98, No. 2, p 146-172, October, 1983. 21 Fig, 3 Tab, 22 Ref.

Descriptors: *Phytoplankton, *Grand River, *Lake Erie, *Ontario, *Water pollution effects, Biomass, Plant communities, Nutrients, Phosphorus, Eutrophication, Water quality.

The phytoplankton in the region of the Grand River and adjacent northeastern Lake Erie (Ontario, Canada) was investigated during April-November of 1979 to determine the influence of the river on the phytoplankton of the lake. Average phytoplankton biomass ranged from 0.45 cu mm/l in the lake to 7.6 cu mm/l in the river mouth. The phytoplankton communities of the two river mouth stations were most similar, but were related to those at the Lake Erie stations at much lower percentage similarities. Stations west of the Grand River were more similar to each other in phytoplankton community structure than to stations east of the Grand River. The influence of the Grand River on Lake Erie phytoplankton was greatest during spring. The distribution of two indicator species, Skeletonema potamos (Weber) Halse and Stephanodiscus hantzschii Grun., suggests that the major influence of the Grand River during the summer was confined to an area within only 5-10 km of the river mouth. The nutrient and phytoplankton data imply that further controls on phosphorus loading will achieve lower densities of algae and improved water clarity, especially in the river mouth area. (Author's abstract)

A COMPARATIVE SURVEY OF ANCYLUS FLUVIATILIS (MULLER) POPULATIONS IN THE AFON CRAFNANT, N. WALES, ABOVE AND BELOW AN INPUT OF ZINC FROM MINE-WASTE,
Liverpool Univ. (England). Dept. of Zoology.
M. Willis.
Archiv fur Hydrobiologie, Vol. 98, No. 2, p 198-214, October, 1983. 5 Fig, 2 Tab, 20 Ref.

Descriptors: *Acylus, *Snails, *Zinc, *Water pollution effects, *Afon Crafnant, *Wales, Mine wastes, Reproduction, Population dynamics, Heavy metals, Toxicity.

The growth, reproductive success and population dynamics of Ancylus fluviatilis (Muller) were studied in a stream receiving zinc from mine-waste at two sites, one upstream and one downstream of the input, over an 18 month period. Samples were collected monthly by clearing 25 quadrats of all Ancylus at each site. Shell dimensions were measured using a binocular microscope with calibrated eyepiece and dial calipers. Histological techniques were employed to determine sexual maturity. Reproductive success was measured by estimating the number of egg-capsules and number of eggs per capsule at each site. Wet ashing techniques followed by analysis using flame atomic adsorption spectrophotometry were used to determine the extent of bioaccumulated zinc. 'Total' zinc and several other metals in the waters were measured using flame atomic adsorption spectrophotometry. A small density of Ancylus was found at the site influenced by zinc. Spring-growth commenced approximately one month later at this site but a similar growth rate of the spats occurred during the summer months. Fewer eggs were found, egg-capsules were more likely to be empty and were smaller at the site influenced by zinc. More zinc was accumulated in the tissues of Ancylus at this site. (Author's abstract)
W84-03490

PROPERTIES OF ACID BROWN WATER STREAMS IN SOUTH SWEDEN,
Lund Univ. (Sweden). Dept. of Animal Ecology.
C. Otto, and B. S. Svensson.
Archiv fur Hydrobiologie, Vol. 99, No. 1, p 15-36, December, 1983. 8 Fig, 5 Tab, 56 Ref.

Descriptors: *Acid streams, *Sweden, *Biological properties, *Chemical properties, Hydrogen ion concentrations, Water pollution effects, Alkaline water, Light penetration, Aquatic fauna.

Whether direct or indirect, pH influences the composition of the fresh water fauna. Based on data from about 300 streams in southern Sweden, the lower pH levels at which common lotic invertebrates have been observed reveal that pH alone is not responsible for the documented impoverished fauna in acid/humic watersheds. A shredder, Potamophylax cingulatus, grew significantly larger in acid as compared to neutral and alkaline streams, despite evidence of physiological stress at low pH. An extended availability of leaf material was documented in the acid stream. A significant positive correlation between number of macroinvertebrate species and pH was established. Shredders and grazers were less abundant at low pH, whereas no significant correlation with pH was found for number of species of deposit feeders, filter feeders and predators. Relationships between pH, organic carbon, aluminum and light transmission were investigated from data obtained in 25 brown water streams. It is suggested that light penetration at the bottom might be a limiting factor for primary production in such streams during the summer. Accumulation of aluminum in P. cingulatus larvae was low despite high background levels. The observation indicates that transport of aluminum from humic waters to terrestrial food chains is not very high. (Murphy-IVI)

5D. Waste Treatment Processes

STUDIES ON STABILIZATION PONDS FOR DOMESTIC SEWAGE IN INDIA,
Government Post Graduate School, Sehore (India). Dept. of Botany.
A. V. Rao.
Internationale Revue der Gesamten Hydrobiologie, Vol. 68, No. 3, p 411-434, 1983. 14 Fig, 15 Tab, 19 Ref.

Descriptors: *Stabilization ponds, *Domestic wastes, Biological oxygen demand, Chemical oxygen demand, Phosphates, Ntrogen, Bottom sediments, Chemical properties.

For one year a single cell stabilization pond, T. T. Nagar, Bhopal (August, 1968 to July, 1969) and series stabilization ponds, Shahpur, Bhopal (January, 1969 to December, 1969) were studied. Climatological conditions in Bhopal were favorable for

the treatment of sewage in stabilization ponds. There was a considerable reduction in BOD, total nitrogen, phosphate, coliforms and enterococci during the process of treatment. The reductions were highest in series ponds. Diurnal variations had the highest pH, dissolved oxygen, algal cell number and lowest alkalinity values occur around 4.00 p.m. Algal flora present in the single cell pond consisted of 31 species representing 27 genera. In the series ponds 33 species belonging to 30 genera and 37 species belonging to 33 genera were in the primary and secondary ponds, respectively. (Murphy-IVI)

BIOTECHNOLOGY AND EFFLUENT TREATMENT,
A. D. Wheatley, C. I. Winstanley, and L. Cassell.
Effluent and Water Treatment Journal, Vol. 23, No. 8, p 307-316, August, 1983. 4 Fig, 4 Tab, 9 Ref.

Descriptors: *Wastewater treatment, *Water reuse, Activated sludge process, Filtration, Bioscrubbing, Adsorption, Biogas, Rotating biological contactors, Biological wastewater treatment.

Existing effluent treatment is reviewed emphasising processes available for by-product recovery and discussing the future prospects for environmental biotechnology for further recovery of useful materials and the breakdown of recalcitrants. The most recent change in biological filtration has been the introduction of plastic media in 1970, extending the range of applications to include high concentration wastes typical of industrial effluents. Another innovation has been the rotating biological contactor (RBC) in which a honeycomb of plastic sheets are slowly rotated on a shaft through a tank containing the wastewater. Developments in the activated sludge processes include the use of pure oxygen in completely enclosed tanks in 1972. An innovative application to effluent treatment was the use of a deep air lift fermenter. Advancements are also considered in the areas of removal by adsorption, bioscrubbing, biogas, and the recovery of biomass. (Baker-IVI)

AERATED LAGOON SYSTEMS WITH IMPROVED PERFORMANCE,
Clemson Univ., SC. Dept. of Environmental Systems Engineering.
L. G. Rich.
Public Works, Vol. 114, No. 4, p 35-36, 1983. 2 Fig, 2 Tab.

Descriptors: *Aerated lagoons, *Wastewater treatment, Domestic wastes, Biochemical oxygen demand, Total suspended solids, Design criteria.

A dual-multicellular aerated lagoon system is described which offers a low-cost alternative to high-maintenance, mechanically complex secondary treatment systems, especially for the treatment of small domestic wastewater discharges. For domestic wastewaters such systems consist of a first cell in which sufficient aerator power (about 30 hp per million gallons of basin capacity) is applied to maintain all organic solids in suspension. It is followed by three cells, each of which is aerated at a power level (from 5 to 10 hp per million gallons of basin capacity) that permits the settleable fraction of the suspended solids in the effluent from the first cell to settle. Solids that settle form deposits in which the biodegradable materials decompose in a benthal environment, giving off methane gas. Removal of soluble biochemical oxygen demand is enhanced by the multicellular configuration of the system and the high concentration of bacterial biomass kept in suspension in the first cell. Low effluent suspended solids are achieved by the multicellular configuration and by limiting the hydraulic retention time. For domestic wastewaters treated in the southeast the retention time in the first cell should be no more than 1.5 days and that in each of the other cells should be no more than about 1.2 days. As the system is relatively small in size, nonbiodegradable solids which accumulate at the bottom of the second, third, and fourth cells should be removed annually. However, these solids should be highly stable and ready for land disposal. (Baker-FRC)

ANTICIPATE FUTURE REQUIREMENTS FOR WASTEWATER HANDLING SYSTEMS,
Bechtel Associates, Ann Arbor, NJ.
J. O. Thaler, and P. K. Sinha.
Power Engineering, Vol. 87, No. 2, p 52-55, 1983. 2 Tab.

Descriptors: *Wastewater treatment, *Regulations, *Legislation, Industrial wastes, Powerplants, Ash, Bottom ash, System design, Design criteria, Wastewater treatment facilities.

Wastewater handling is a subject of growing concern to operating power plants. Many National Pollutant Discharge Elimination System (NPDES) permits have expired, or are expiring, and there will be no definitive federal position on pollutant discharge until the effluent guidelines are finalized and promulgated. The EPA is currently active in reviewing the overall Clean Water Act and is drafting proposed revisions to be submitted soon to Congress. Limitations established up to this point are considered. The finalized first round regulations separated power plant discharges into six controlled waste categories: once through cooling water, recirculating cooling water system blowdown, ash transport water (fly ash and bottom ash), metal cleaning wastes and boiler blowdown, low-volume wastes (collective), and all categories. First round best practical control technology available limitations were aimed at controlling the discharge of free available chlorine, total suspended solids, oil/grease, pH, copper and iron. They also specified total elimination of discharges containing PCB compounds. First round NSPS (new source performance standards) limitations were similar but contained some limitations even more strict than best available technology limits. Management considerations must be given to total residual chlorine in once-through cooling water discharges, TRC in recirculating cooling water system blowdown, bottom ash transport systems, water based metal cleaning wastes, and coal pile precipitation runoff. (Baker-FRC)

THE INFLUENCE OF FLOW CONDITIONS ON THE REMOVAL OF HEAVY METALS IN THE PRIMARY SEDIMENTATION PROCESS,
Imperial Coll. of Science and Technology, London (England). Public Health Engineering Lab.
A. C. Rossin, R. M. Sterritt, and J. N. Lester.
Water, Air, and Soil Pollution, Vol. 19, No. 2, p 105-121, 1983. 2 Fig, 7 Tab, 31 Ref.

Descriptors: *Heavy metals, *Wastewater treatment, Chromium, Copper, Lead, Nickel, Zinc, Cadmium, Flow, Suspended solids.

A pilot scale primary sedimentation pilot plant, treating raw sewage was used to assess the efficiency of removal of cadmium, chromium, copper, nickel, lead, and zinc. Heavy metal removals were determined during conditions designed to simulate normal dry weather flow, three times dry weather flow and diurnal variations in flow. During the study, the flows of sewage to the works where the pilot plant was were also varied. The efficiency of sewage treatment processes in removing heavy metals depends on two main factors: namely their existence as settleable particulate forms in the sewage and the conversion of soluble and non-settleable forms within the process. The heavy metal removal efficiencies in the primary sedimentation pilot plant varied considerably not only in terms of the effects of hydraulic loading on the process, but also on different sampling occasions at the same hydraulic loading. These variations may have been due to the manner of heavy metal input to the process. It appeared that metal input was not a continuous process, since data indicated that the concentrations of Cd, Cu, Pb, and Zn could increase by a factor of 2 to 3, and then return to initial concentrations in periods as short as 12 hr. In spite of the variations in concentrations of heavy metals in the sewage, the variations in percentage removals of heavy metals were much less and those variations in removal which did occur did not appear to be related to the heavy metal concentration. Metal removal was adversely affected by increasing the flow by a factor of three and by operating the plant under variable flow conditions. Suspended solids removal was not affected by increasing the flow. (Baker-FRC)

INDUSTRIAL WASTE ELIMINATION - AN OPTIMAL SOLUTION,
Industrial Waste Elimination Research Center, Chicago, IL.
J. W. Patterson, and W. A. Cawley.
Industrial Wastes, Vol. 29, No. 2, p 10-13, March/April, 1983. 4 Tab.

Descriptors: *Industrial wastes, *Wastewater treatment, Industrial Wastes Elimination Research Center, Water pollution control, Metals, Management, Planning.

The historical and still current approach to industrial pollution control has been end-of-pipe treatment and discharge of the treated effluent. This end-of-pipe approach evolved to control conventional pollutants such as biochemical oxygen demand and suspended solids and, in most instances, remains valid for control of such pollutants. However today we are also concerned with the identification and control of a wide spectrum of toxicants, and innovative approaches and methodologies must be considered for treating them. The concept of pollution avoidance is gaining increasing acceptance as an alternative to conventional approaches to pollution control. It is an inherently attractive concept in that it addresses the opportunities to conserve valuable resources while avoiding the costs and environmental risks of ultimate waste dispersal. The Industrial Wastes Elimination Research Center (IWERC) has five research projects currently being coordinated and funded including projects focusing on metals recovery, sorption/desorption recovery for organics, liquid-liquid membrane extraction techniques for organics and metals and catalysts. Most of the funding currently comes through block grants from EPA. (Murphy-IVI)

THE ANAEROBIC APPROACH: A BETTER ANSWER,
Celanese Chemical Co., Bishop, TX.
L. M. Harvey, and J. C. Rubiano.
Industrial Wastes, Vol. 29, No. 2, p 22-25, March/April, 1983. 2 Fig, 2 Tab.

Descriptors: *Wastewater treatment, *Anaerobic conditions, Industrial wastes, Celanese Chemical Company, Bishop, Texas, Chemical wastes, Activated sludge process.

An anaerobic wastewater treatment process has been developed for high-strength industrial wastewaters. The system pretreats wastes in one location in order to reduce organic concentration for municipal discharge. At another location the same system, followed by aerobic polishing, provides organic COD reduction and odor abatement on chemical wastes prior to disposal in solar evaporation ponds. At the Celanese facility in Bishop, Texas a retrofit of the system to an existing activated sludge unit has expanded the plant's capacity and made possible the biodegradation of wastes which were previously classified as untreatable. The anaerobic system was expected to lower operating costs as a result of reduced aeration requirements of the aerobic system, net fuel value of the offgas produced in the anaerobic reactor, and reduced sludge production. The combined Celrobic anaerobic reactor and activated sludge system will provide for treatment of greater than 95% of the

plant's organic wastewaters through the 1980s. (Baker-IVI)

TRANSFERABLE DISCHARGE PERMITS AND ECONOMIC EFFICIENCY: THE FOX RIVER,
Colby Coll., Waterville, ME. Dept. of Economics.
W. O'Neill, M. David, C. Moore, and E. Joeres.
Journal of Environmental Economics and Management, Vol. 10, p 346-355, 1983. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Wastewater disposal, *Economic efficiency, *Permits, *Fox River, Wisconsin, Economic feasibility, Cost analysis, Economic evaluation, Systems analysis, Computer models, Mathematical models, Pollution load, Water pollution control.

Recent emphasis on reforms of environmental regulation has led to suggestions for strategies which maintain environmental standards but allow the needed flexibility and cost effectiveness. The transferable discharge permit (TDP) is one such strategy for water pollution control recently adopted in Wisconsin. There was substantial cost savings from trading TDPs from data on the Fox River in Wisconsin. A simulation model of water quality (Qual-III) and a linear programming model of abatement costs determine the optimum pattern of discharge. Reaching that optimum from proposed pollution abatement orders is feasible. Varying conditions of flow and temperature can be accommodated using trade coefficients which can be accurately estimated through interpolation. The calculations are valuable and feasible in conjunction with the flexible regulations governing water pollution abatement. There is no obstacle to trading permits even when the permit itself varies in proportion to the assimilative capacity of the river. (Murphy-IVI)

SUBSURFACE INJECTION OF TREATED SEWAGE INTO A SALINE-WATER AQUIFER AT ST. PETERSBURG, FLORIDA - AQUIFER PRESSURE BUILDUP,
Geological Survey, Tampa, FL.
J. J. Hickey.
Ground Water, Vol. 22, No. 1, p 48-55, January-February, 1984. 6 Fig, 10 Ref.

Descriptors: *Florida, *St. Petersburg, *Injection wells, *Underground waste disposal, *High pressure, *Aquifers, *Confined groundwater, Wastewater disposal, Chlorides, Groundwater movement, Municipal wastewater.

The city of St. Petersburg has been testing subsurface injection of treated sewage into the Floridan aquifer as a means of eliminating discharge of sewage to surface waters and as a means of storing treated sewage for future non-potable reuse. The injection zone originally contained native saline ground water that was similar in composition to sea water. The zone has a transmissivity of about 0.0000012 sq feet/day and is within the lower part of the Floridan aquifer. Treated sewage that had a mean chloride concentration of 170 (mg/l) was injected through a single well for 12 months at a mean rate of 0.000047 cubic feet/day. The volume of water injected during the year was 1.7 times 10 to the 8th power cubic feet. Pressure buildup at the end of one year ranged from less than 0.1 to as much as 2.4 pounds/sq inch in observation wells at the site. Pressure buildup in wells open to the upper part of the injection zone was related to buoyant lift acting on the mixed water in the injection zone in addition to subsurface injection through the injection well. Calculations of the vertical component of pore velocity in the semi-confining bed underlying the shallowest permeable zone of the Floridan aquifer indicate upward movement of native water. This is consistent with the 200 to 600 mg/l increase in chloride concentration observed in water from the shallowest permeable zone during the test. (Author's abstract)

MODELS FOR WATER REUSE AND WASTEWATER PLANNING,
California State Water Resources Control Board, Sacramento.
M. Schwartz, and L. W. Mays.
Journal of Environmental Engineering, Vol. 109, No. 5, p 1128-1147, October, 1983. 3 Fig, 5 Tab, 16 Ref.

Descriptors: *Mathematical models, *Water reuse, *Wastewater management, *Optimum development plans, Management planning, Cost analysis, Water treatment facilities, Maintenance costs, Operating costs, Costs, San Antonio, Texas.

The concepts of both water conservation and reuse are important in obtaining the maximum utility of water resources. A planning model for the determination of optimal water reuse allocation and wastewater treatment alternatives minimizes the overall cost of water supply and wastewater treatment over a planning period. The planning model consists of two models, each based upon dynamic programming (DP). The first model is an allocation DP model, which is used for the optimal allocation of water to users for each treatment alternative considered. The second model is a treatment DP model, which performs the optimal selection of treatment alternatives over time. The allocation DP model is used to define the state space for the treatment DP model. Application of the planning model is made to San Antonio, Texas. (Murphy-IVI)

LAGOON EFFLUENT POLISHING WITH INTERMITTENT SAND FILTERS,
Carollo (John) Engineers, Phoenix, AZ.
J. S. Russell, E. J. Middlebrooks, R. F. Lewis, and E. F. Barth.
Journal of Environmental Engineering, Vol. 109, No. 6, p 1333-1353, December, 1983. 11 Tab, 9 Ref.

Descriptors: *Wastewater lagoons, *Effluent polishing, *Sand filters, *Intermittent filters, Municipal wastewaters, Water quality, Water quality standards, Secondary wastewater treatment, Cost analysis, Biochemical Oxygen demand.

Intermittent sand filters are economical and as simple to operate as wastewater lagoons. All but one of the three lagoon-intermittent sand filter systems treating municipal wastewaters monitored satisfied the 1972 federal secondary treatment discharge standards for BOD5, and that facility removed 84% of the BOD5 instead of the required 85% removal. The 30-day mean effluent BOD5 concentrations for all three systems ranged from 3-21 mg/L with a percentage removal range of 84%-98%. The 30-day mean effluent SS concentrations ranged from 8-21 mg/L. Eighty five percent removal of SS was not achieved during two of the nine sampling periods. At no time did the 30-day geometric mean effluent fecal coliform concentration of the three systems exceed 200 organisms/100 ml. Geometric mean fecal coliform concentrations of less than 200 organisms/100 ml were produced without disinfection. Only three of 260 effluent samples had a pH value that did not lie within the required range of 6.0 to 9.0. Total treatment costs for the three filters evaluated ranged from $0.04-$0.06 per cu m of filtrate. (Murphy-IVI)

TREATMENT PLANTS ENTER COMPUTER IMMERSION PHASE,
V. von Buchstab.
Water and Pollution Control, Vol. 121, No. 2, p 18-22, March/April, 1983.

Descriptors: *Water treatment facilities, *Computers, *Wastewater treatment, Management, Cost-benefit analysis, Energy, Financial aspects.

The most immediate benefits of entering the computer immersion phase has been reduced labor costs and reassignments leading to higher maintenance orientation in some plants. The common thread running through the interviews with management of wastewater treatment and water treatment facilities was that municipalities, like all other clients, need to know the cost/benefits of their expenditures. Manpower savings are the best documented incentives to automate. Other factors include energy savings. Control schemes are now scavenging the energy content of sewage off-gases, for such functions as heating the digestion processes to optimal temperatures, or the use of methane to drive small, auxillary motors. More importantly, load-shedding schemes mean reduced hydrodemand charges by thoughtful load staggering. (Murphy-IVI)

NEW WATER AND WASTEWATER SYSTEMS FOR ELLIOT LAKE,
S. Davey.
Water and Pollution Control, Vol. 121, No. 5, p 8-10, 17, 33, September/October, 1983. 5 Fig.

Descriptors: *Water treatment facilities, *Wastewater treatment facilities, Elliot Lake, Activated sludge process, Chlorination, Filtration, Fluoridation, Design criteria, Planning, Decision making.

In the past two years $24 million has been spent on new water and sewage systems for Elliot Lake. The existing water plant was to be replaced with a 29,100 cubic m/day water treatment plant incorporating filtration, fluoridation and chlorination, designed to supply a population of 28,000. The plant's source of water is Elliot Lake, situated deep in the granitic Canadian shield. In addition the Estern Lake Sewage Treatment Plant was commissioned in December 1981 after only 11 months of construction. This plant uses a conventional activated sludge process to provide secondary treatment of a nominal design flow of 16,000 cubic m/day and a peak of 36,000 cubic m/day. Both systems are owned and operated by the town. (Baker-IVI)

OCCURRENCE OF LOW- AND HIGH-CHLORINATED PHENOLS IN MUNICIPAL SEWAGE BEFORE AND AFTER PASSING THROUGH BIOLOGICAL TREATMENT PLANTS,
Vandkvalitetsinstitutet, Hoersholm (Denmark).
J. Folke, and U. Lund.
Journal of Chromatography, Vol. 279, p 189-198, 1983. 3 Fig, 2 Tab, 18 Ref.

Descriptors: *Wastewater analysis, *Chlorinated phenols, *Biological wastewater treatment, Gas chromatography, Mass spectrometry, Phenols, Denmark.

Four Danish biological treatment plants for municipal sewage (located in the center of Copenhagen, in the Greater Copenhagen area, in a provincial town in Jutland with 56,000 inhabitants, and in a provincial town on Sealand with 29,000 inhabitants) were examined for their chlorophenol content and their ability to degrade these compounds. None of these plants was known to be charged with industrial wastewater containing chlorophenols. A routine method for the analysis of both low- and high-chlorinated phenols was developed, based on gas chromatography with electron-capture detection (GC-ECD). The method was evaluated by comparing the GC-ECD results with those obtained by combined gas chromatography-mass spectrometry with selected-ion monitoring, GC-MS(SIM), of the molecular ions of the specific phenols. The sensitivity of the GC-ECD method for the individual phenols increases with increasing number of chloro substituents The GC MS(SIM) method is better for the determination of low- and non-chlorinated phenols. The GC-ECD method has a greater sensitivity for the higher chlorinated phenols. The advantage that the GC-MS(SIM) method is free from errors caused by interfering compounds must be weighed against the advantages of the GC-ECD method, which is less costly with regard to instruments and more easily adapted to routine analyses. The total phenol content, determined by GC-ECD showed a good correlation with the phenol number, obtained by using the 4-aminoantipyrine method. (Moore-IVI)

SEPARATION OF BACTERIA FROM A METHANOGENIC WASTEWATER POPULATION BY UTILIZING A SELF-GENERATING PERCOLL GRADIENT,
Hamburg Univ. (Germany, F.R.). Inst. fuer Allgemeine Botanik.
P. Scherer.
Journal of Applied Bacteriology, Vol. 55, No. 3, p 481-486, December, 1983. 1 Fig, 13 Ref.

Descriptors: *Bacterial analysis, *Density gradient separation, *Wastewater analysis, *Methane bacteria, Wastewater treatment, Sulfur bacteria, Methanosarcina, Methanothrix, Desulfovibrio.

Percoll consists of polyvinylpyrrolidone coated colloidal silica-gel particles which form a distribution of nearly spherical particles with a mean diameter of 17-30 nm. Bacteria from a methanogenic wastewater population could be separated with a self-generating density gradient of Percoll. The separation was performed by centrifugation for 30 min at 30000 g in a simple angle-head rotor. Three types of bacteria were concentrated to apparent homogeneity in different bands: these were attributed to the methanogens Methanosarcina and Methanothrix, and to the dissimilatory sulfate-reducing bacterium Desulfovibrio. By the addition of colored marker beads with a known density, the buoyant density of fractions can be estimated in the same centrifugation. This method should facilitate bacterial analysis of wastewater and should contribute to the understanding of the bacteria concerned with wastewater treatment. (Moore-IVI)

SLUDGE TREATMENT BY OXYOZOSYNTHESIS STOPS OCEAN DUMPING,
S. A. Peterson, and E. Mozell.
Public Works, Vol. 15, No. 1, p 42-43, January, 1984. 1 Fig, 1 Tab.

Descriptors: *Sludge treatment, *Oxyozosynthesis, *Sludge disposal, Sludge cake, Ozone, Oxygen, Cost analysis, West New York, New Jersey.

West New York's (New Jersey) sewage is treated by primary clarifyers. The sludge is moved into a 3,000-gallon pressurized reactor vessel where oxyozosynthesis treatment takes place. The atmosphere within the reactor consists of a 2:1 ratio of oxygen to ozone at a pressure of 60 psi. The source of ozone is a generator that converts oxygen gas to ozone. The total pressurizing and processing time per batch is 90 minutes. The process converts the sewage sludge into CROAL, an odorless, almost completely sterile cake. The CROAL, which more than meets federal and New Jersey standards for land application, is trucked to a nearby landfill. Before adopting the oxyozosynthesis process, the town disposed of sludge by ocean dumping, at an annual cost of $170,000; total annual cost for treatment by the oxyozosynthesis process is only $110,000. DECHLORINATION OF WASTEWATER AND COOLING WATER,
Maryland Univ., College Park. Dept. of Chemistry.
G. R. Helz, and L. Kosak-Channing.
Environmental Science and Technology, Vol. 18, No. 2, p 48A-55A, February, 1984. 87 Ref.

Descriptors: *Dechlorination, *Wastewater treatment, *Cooling water, Environmental effects, Effluents, Reviews, Sulfur dioxide.

A growing movement is under way in the United States to install dechlorination facilities, particularly at sewage treatment plants, to alleviate damage to downstream ecosystems. A thorough review determined that research is needed in treatment technology, downstream chemical effects and downstream biological effects of dechlorination. In treatment technology better SO2 application and control systems are needed. For downstream chemical effects, the effect of S(IV) compounds on trace metal geochemistry is important, particularly whether S(IV) compounds cause reductive dissolution of the Fe and Mn oxyhydroxides in a river's suspended load. To determine the effectiveness of dechlorination long-term and sublethal effects, such as effects on reproduction and avoidance behavior, are also necessary. (Murphy-IVI)

TECHNICAL NOTE: ADSORPTION OF P-DICHLOROBENZENE FROM WATER,
M. Pirbazari, and W. J. Weber, Jr.
Journal American Water Works Association, p 82-84, February, 1984. 4 Fig, 9 Ref.

Descriptors: *Adsorption, *Dichlorobenzene, Granular activated carbon, Humic acids, Water treatment.

The results of granular activated carbon adsorption studies for para-dichlorobenzene from water in the presence of a major class of naturally occurring compounds - humic acids, is presented. With a load of PDB as high as 185 micrograms/liter an empty bed contact time of only 0.17 min, and a hydraulic loading of 2.6 mm/sec, approximately 78,800 bed volumes of water were treated before an effluent breakthrough level of 1 microgram/liter was reached. The effectiveness of activated carbon for PDB removal appears not to be adversely affected by background organics such as humic acids. PDB adsorption by carbon appears readily reversible, suggesting that uptake from solution occurs primarily because of relatively weak van der Walls' attraction forces. The MADAM model was generally able to simulate and predict the performance of fixed-bed adsorbers for removal of PDB. (Baker-IVI)

TREATMENT OF ALKALINE WASTEWATER FROM LIGNITE-FIRED POWER PLANTS,
Wroclaw Technical Univ. (Poland). Inst. of Environment Protection Engineering.
A. M. Dziubek, and A. L. Kowal.
Water Science and Technology, Vol. 15, No. 11, p 155-162, 1983. 4 Fig, 2 Tab, 7 Ref.

Descriptors: *Wastewater treatment, *Alkaline water, Powerplants, Lignite, Aeration, Chemical composition, Calcium carbonate, Carbonates.

Alkaline wastewaters produced in the hydrotransport of some lignite ashes from the powerplant to the storage site have a high acidity and a high total hardness, so they cannot be discharged into a natural water course without treatment. Recommended are the attenuation of the alkalies contained in them, and precipitation of calcium carbonate. These experiments have substantiated the efficiency of recarbonation and aeration, two treatment procedures which may be of importance from the environmental viewpoint in that they employ no additional chemicals. As a result of aeration pH was decreased to a level of about 7.8, and alkalinity to a level of 30 to 50 g calcium carbonate/cu m, irrespective of the initial alkalinity value. The minimum time of aeration required to achieve the highest degree of precipitation varied from 4 to 8 hr, depending on the initial alkalinity level. Expended times of aeration required in the recarbonation process can be shortened by employing primary recarbonation with pure carbon dioxide or flue gases unitl a pH of 9.5 is reached. The further decrease of pH can be achieved by aeration. An additional advantage of this method is that the flocculation conditions for the precipitated calcium carbonate are evidently improved and the time needed for sedimentation is shortened following the recarbonation process. LANDFILL LEACHATE TREATMENT,
Pennsylvania Univ., Philadelphia. Dept. of Civil and Urban Engineering.
J. D. Keenan, R. L. Steiner, and A. A. Fungaroli.
Journal of the Water Pollution Control Federation, Vol. 56, No. 1, p 27-33, January 1984. 1 Fig, 9 Tab, 7 Ref. EPA grant S-803926.

Descriptors: *Leachates, *Landfills, *Wastewater treatment, Municipal wastewater, Industrial wastes, Heavy metals, Copper, Iron, Mercury, Zinc, Nickel, Lead, Sedimentation, Ammonia stripping, Neutralization, Activated sludge processes.

Landfill leachate is often a high-strength wastewater characterized by extremes of pH, biochemical oxygen demand, chemical oxygen demand, and heavy metals. In addition, it is a wastewater which is variable from landfill to landfill, and over time and space at a particular landfill. Consequently, neither biological waste treatment nor chemical-physical treatment separtely achieves high removal efficiency. The leachate treatment facility used in this study is located at a landfill in Falls Township, Bucks County, Pa. The plant is designed to provide maximum operational flexibility to permit full-scale testing of a variety of treatment sequences. The sanitary landfill has a surface area of 50 acres, receives about 800 tons of refuse per day, 85% of which is municipal. The balance is industrial sludges and solid waste. The leachate is characterized by high concentrations of organic compounds which vary significantly day-to-day. Activated sludge treatment of the effluent from the chemical/physical units was extremely successful. The reduction in ammonia-N afforded by the ammonia stripping lagoon provided conditions suitable for the growth of activated sludge microorganisms. Overall the treatment sequence of lime precipitation, sedimentation, ammonia stripping, and neutralization followed by activated sludge produced an excellent final effluent with the following characteristics: organic matter reduced to 153 mg BOD-5/l, a 99% reduction; an effluent ammonia concentration of 75 mg/l which represented a 90% removal; and heavy metal concentrations of 0.07 mg chromium/l, 0.11 mg copper/liter, 2.7 mg iron/l, 0.12 mg lead/l, 0.004 mg mercury/l, 0.75 mg nickel/l and 0.53 mg zinc/l. RENOVATION OF WASTEWATER AT THE 23RD AVENUE RAPID INFILTRATION PROJECT,
H. Bouwer, and R. C. Rice.
Journal of the Water Pollution Control Federation, Vol. 56, No. 1, p 76-82, January, 1984. 2 Fig, 5 Tab, 16 Ref. EPA project S-802435.

Descriptors: *Wastewater treatment, *Infiltration, Water reuse, Activated sludge treatment, Soil-aquifer treatment, Ammonia, Phosphates, Coliforms, Irrigation, Recreation demand.

In arid areas, wastewater is an important resource that can be used for irrigation, recreational lakes, power plant cooling, and even for municipal purposes with adequate treatment. Where hydrogeologic conditions and land availability are favorable for groundwater recharge with infiltration basins, considerable quality improvement of the wastewater can be obtained by soil-aquifer treatment (SAT). An oxidation pond of 16 ha below the Phoenix 23rd Avenue Sewage Treatment Plant was split into four parallel infiltration basins to study large-scale renovation of secondary effluent by soil-aquifer treatment obtained by groundwater recharge using rapid infilration basins. The resulting renovated water can be pumped from the aquifer for unrestricted irrigation and recreational

lakes. Where the wastewater is to be recycled for drinking, soil-aquifer filtration provides an effective pretreatment of the water for activated carbon treatment, reverse osmosis, and disinfection. (Murphy-IVI)

SOIL-AQUIFER TREATMENT USING PRIMARY EFFLUENT,
R. C. Rice, and H. Bouwer.
Journal of the Water Pollution Control Federation, Vol. 56, No. 1, p 84-88, January, 1984. 6 Fig, 4 Tab, 8 Ref.

Descriptors: *Wastewater treatment, *Municipal wastes, Soil aquifer treatment, Suspended solids, Soil properties, Infiltration, Permeability coefficient.

Soil aquifer treatment of primary effluent is able to produce renovated water of equal or better quality than that obtained when using secondary effluent. The soil system can handle the higher organic carbon load of the primary effluent and provide adequate removal of bacteria and viruses. The infiltration capacity of the system depends on the hydraulic conductivity of the soil and the concentration and composition of the suspended solids. When the suspended solids are largely organic, most of the solids will accumulate on the soil surface where they are rapidly decomposed. Infiltration rates are restored after drying or by scarifying the surface by raking or harrowing. When the effluent contains fine inorganic solids, in-depth clogging may occur. The fine particles migrate downward and do not decompose, so that annual deep cultivation is needed to break up the clogged zone. A hydraulic loading capacity of 27 to 51 m/yr was obtained with an inundation schedule of 1 week wet and 1 week dry in the winter. This hydraulic loading represented 5 to 8% of the infiltration capacity of the soil or about 50% of the infiltration capacity expected for secondary effluent. Using primary effluent bypasses the expensive and energy-consuming secondary treatment process and provides renovated water at a lower cost, provided that land prices are not prohibitively high. FLOCCULENT SETTLING IN QUIESCENT SYSTEMS,
Geraghty and Miller, Inc., Baton Rouge, LA.
T. Y. R. Lo, and W. J. Weber, Jr.
Journal of Environmental Engineering, Vol. 110, No. 1, February, 1984. 12 Fig, 2 Tab, 16 Ref.

Descriptors: *Sedimentation, *Flocculent settling, *Settling rates, Suspended solids, Wastewater treatment, Settling velocity, Wastewater, Mathematical equations.

Characterization of the setting properties of suspensions for purposes of settling basin design and for prediction of suspended solids behavior in natural water systems is traditionally based on observations of settling rates of dilute suspensions in quiescent columns. Most suspensions of practical interest for water and waste treatment systems and natural aquatic environments are flocculent in character, and their settling cannot be described accurately in terms of minimum settling velocities. An empirical equation for description of the distribution of flocculent solids in quiescent settling columns was developed. The equation is predicated on observations made in the course of concentration-depth-time analyses of settling data for flocculent and nonflocculent solids in quiescent and agitated settling columns. The validity of the equation is verified by its application to ten different quiescent flocculent settling studies involving several sewages and natural lake and river suspensions. Application of the equation involves evaluation of two parameters: the flocculation coefficient and the discrete-equivalent velocity distribution. (Moore-IVI)

Journal of Environmental Engineering, Vol. 110, No. 1, p 263-276, February, 1984. 12 Fig, 4 Tab, 18 Ref.

Descriptors: *Contact filters, *Precipitation, *Phosphorus removal, Wastewater treatment, Iron, Filtration, Polymers.

Pre- or simultaneous precipitation combined with contact filtration for final treatment is an excellent method to achieve low phosphorus residuals in waste-water discharges to lakes. The two dosing steps are optimized to allow for log chemical use and sufficiently long filter runs. If an Fe/P dissolved-ratio of about 2.0 is used in the first step, the Fe(III)-dosage to the second step may be kept below 4 g Fe(III)/cu m. This allows the precipitates together with the solids from the secondary clarifier to be removed in multi-media filters. The unfavorable filtering characteristics of the precipitates may be improved by dosing filter aids. In laboratory scale experiments low concentrations of nonionic polyacrylic polymers with high molecular weight showed best filter performance. Under optimized conditions with respect to precipitant and filter aid dosage, a full-scale treatment plant was investigated. Consistent low phosphorus residuals at 0.1-0.2 g P/cu m was reached at mean filtration rates of 7.4 m/h and average filter runs of 20 hr. (Author's abstract)

THE HANDLING AND DISPOSAL OF COAL ASH IN THE CEGB IN RELATION TO THE AQUEOUS ENVIRONMENT,
Central Electricity Generating Board, Manchester (England). Scientific Services Dept.
J. Brown, and N. J. Ray.
Water Science and Technology, Vol. 15, No. 11, p 11-24, 1983. 1 Fig, 7 Tab, 4 Ref.

Descriptors: *Handling, *Disposal, *Coal ash, *Central Electric Generating Board, *Aquatic environment, Percolation, Coal effluents, Groundwater, Aquifer characteristics, Slurries, Suspended solids.

Pulverised fuel ash (pfa) and furnance bottom ash (fba) are the Principal solid wastes from modern coal fired plants. These residues are often handled and disposed of as slurries and pfa is frequently used for the reclamation of derelict land. One factor which requires careful management is the level of suspended solids in the outfall when a lagoon is nearly full. Whether ash is disposed of wet, or merely conditioned with water to facilitate handling, there may be a further need to consider the percolation of water through the ash and its possible interaction with groundwater. This calls for knowledge or study of the ash itself, the size of the area to be reclaimed, the rainfall pattern and the local hydrogeology, including the size and rate of recharge of the aquifer. The basic Central Electricity Generating Board requires the combination of laboratory studies of percolate quality with hydrogeological assessment to evaluate the potential risks, if any. The actual consent to dispose of ash taking such factors into account, is made by the Local Authority in consultation with the Water Authority. The present view of ash disposal relative to the aqueous environment could be disturbed if legislation and the associated Codes of Practice were to become more stringent. (Murphy-IVI)

STUDIES ON THE LEACHING AND WEATHERING PROCESSES OF COAL ASHES,
Royal Inst. of Tech., Stockholm (Sweden). Dept. of Inorganic Chemistry.
H. Liem, M. Sandstrom, T. Wallin, A. Carne, and U. Rydevik.
Water Science and Technology, Vol. 15, No. 11, p 163-191, 1983. 15 Fig, 7 Tab, 6 Ref.

Descriptors: *Leaching, *Weathering, *Coal, *Ashes, Computer programs, HALTAFALL, Metals, Hydrogren ion concentration, Mass-action law, Crystallization.

The Swedish project Coal-Health-Environment studies leaching on several types of coal ashes, fly ashes, bottom ashes and scrubber sludges to determine the effects of pH, pCl, pCO3, pEDTA and pSO4 in the leaching solution on the leaching of metals from coal ashes. The leaching of Cr, Co, Ni, Cu, Zn, Mo, Se, As, Cd, and Pb increases with pH for pH less than 2 and pH greater than 9, and decreases for pH greater than 2 but less than 6. The metal leaching behavior may in part be explained by the mass-action law. Through X-ray diffraction techniques the dominating crystalline phases in the different coal ashes were mullite (3Al2 times 2SiO2), alpha-quartz (Si02) and the iron oxides magnetite and hematite. Equilibrium analysis on various metals and compounds were made partly using the computer program HALTAFALL. (Murphy-IVI)

USE OF 'THE CAPILLARY BARRIER' AS A SHIELD AGAINST GROUNDWATER POLLUTION FROM FLY-ASH DEPOSITS,
Danmarks Geologiske Undersoegelse, Copenhagen. Hydrogeological Div.
L. J. Andersen, and B. Madsen.
Water Science and Technology, Vol. 15, No. 11, p 207-212, 1983. 4 Fig, 4 Ref.

Descriptors: *Capillary barrier, *Groundwater Pollution, *Fly ash, Capillarity, Membranes, Permeability, Semipermeable membranes, Leaching, Waste storage.

The enormous amounts of fly ash produced by the burning of coal in power plants have resulted in a number of environmental problems, not least of which is the increased risk of groundwater pollution from its deposition in gravel pits. In order to prevent this pollution, fly ash deposits have often been established with an underlying membrane. Such membrane-systems are quite expensive to build and necessitate a continuous pumping and removal of percolate. The alternative of covering the fly ash with a low-permeable membrane, which removes the infiltrated water laterally, prevents not only groundwater pollution but also the formation of percolate. By using the principle of 'The Capillary Barrier,' the low-permeable membrane can be constructed of natural and resistant porous materials. (Murphy-IVI)

PREVENTION OF WATER POLLUTION BY THE USE OF FLY-ASH AS A SUBSTITUTE FOR EXTRACTED RAW MATERIALS,
Miljoeministeriet, Copenhagen (Denmark).
J. Lyngvig.
Water Science and Technology, Vol. 15., No. 11, p 213-222, 1983. 3 Fig, 3 Tab.

Descriptors: *Waste disposal, *Waste recovery, Industrial wastes, Powerplants, Fly ash, Building materials, Clay, Gravel.

One of the major problems in disposing of big quantities of fly-ash is the possible washing out of heavy metals which may pollute subsoil water. The washing out of chlorides and sulfates is also of concern. The use of fly-ash as a substitution material for gravel and clay has to be regarded as a way of disposing of a waste product as well as a way of saving the limited resources of natural raw materials and also as a technical and economical innovation in the building and construction industries. A brief history of the Raw Materials Act is offered along with a listing of possible applications of waste products, documentation for the use of fly-ash as a substitution material and possibilities for the future. SEDIMENTATION OF ZEOLITE TYPE A IN WATER AND WASTEWATER,
Lisbon Univ. (Portugal).
M. J. T. Carrondo, J. N. Lester, and R. Perry.
Effluent and Water Treatment Journal, Vol. 23, No. 7, p 271, 273-280, July, 1983. 11 Fig, 5 Tab, 29 Ref.

Descriptors: *Detergents, *Water treatment, *Wastewater treatment, Water pollution sources, Phosphorous, Zeolite type A, Aluminosilicates, Sedimentation.

Zeolite type A is a synthetic aluminosilicate which may be used to partly replace phosphorus compounds as detergent builders. The settling behavior of zeolite type A in water and wastewater was investigated. The use of Stokes' law in conjunction with the particle size distribution yields reasonably accurate predictions for the removal of zeolite type A when compared with the results of settling column tests, although the particles are not spherical. The removals computed from the integration of settling curves obtained from column tests compare well with the model tank tests, although the tank removals are marginally lower. Even at low overflow rates, removal of zeolite type A in water was low. As anticipated, zeolite type A in concentrations of about 30 mg/liter was removed at a faster rate from sewage than would be predicted by Stokes' law. When zeolite type A was present in raw sewage at about 30 mg/liter the percentage of suspended solids removed in static column tests was marginally reduced from the values obtained in raw sewage when zeolite was absent. Under flocculant settling conditions in raw sewage zeolite type A was removed to a lesser extent than the other suspended solids, particularly during the initial stages of the settling tests. This might imply lower zeolite type A removals in hydraulically overloaded tanks compared to suspended solids removal. (Baker-IVI)

LEAD IN DRINKING WATER-INVESTIGATION OF A CORROSIVE WATER SUPPLY,
Morris Township Health Dept., Convent Station, NJ.
J. A. Benson, and H. Klein.
Journal of Environmental Health, Vol. 45, No. 4, p 179-181, 1983. 1 Tab, 23 Ref.

Descriptors: *Drinking water, *Lead, *Corrosion, Public health, Water quality, Potable water, Reservoirs, Pollutant identification, Hydrogen ion concentration.

A corrosive water supply in Morris County, New Jersey was investigated and appeared to result from leaching lead out of solder in household plumbing systems. From June through November, 135 water samples were taken from 99 locations in the reservoir service area and analyzed. First flush samples were taken the first thing in the morning, representing water that had been standing in the plumbing overnight. Standing grab samples were taken during the day without allowing the water to run first. Running grab samples were taken, and also composite samples, which were samples taken immediately before use of the water for drinking or cooking. Of the first flush samples 32% showed lead levels in excess of 0.05 mg/l. Children living in these homes had on the average 14 micrograms/dl blood lead. In order to correct the problem the water authority sent notices out to customers to flush their plumbing systems out in the morning prior to use. In addition the pH of the water was raised from about 6.1 to 7.9 by lime addition. The water authority also began replacing the reservoir water with well water purchased from another nearby water authority. (Baker-FRC)

CHLORINATION-FILTRATION FOR IRON AND MANGANESE REMOVAL,
Raymond Kaiser Engineers, Inc., Oakland, CA.
J. M. Wong.
Journal of the American Water Works Association, Vol. 76, No. 1, p 76-79, January, 1984. 4 Fig, 2 Tab, 12 Ref.

Descriptors: *Chlorination, *Filtration, *Iron, *Manganese, Groundwater, Water treatment, Suspended solids, Cost analysis, Pilot plants.

Processes in which oxidation is followed by removal of suspended solids can effectively remove soluble iron and manganese from water. The common processes for removing iron and manganese are aeration-filtration, chlorination-filtration, and potassium permanganate-manganese greensand filtration. The potassium permanganate-manganese greensand filtration has an advantage in that the greensand can act as a buffer. The major disadvantages of the aeration-filtration process are that the initial costs are high and if the soluble manganese concentration is greater than 1 mg/L, additional retention time and supplemental chemical treatment may be required. Chlorination-filtration is often slow and incomplete. At pH 8.4 and above the chlorination-filtration process effectively removes iron and manganese. The costs for oxidants in chlorination-filtration are less than those for potassium permanganate-manganese greensand filtration. (Murphy-IVI)
W84-03142

OVERLAND FLOW FOR IRON REMOVAL FROM POTABLE WATER,
Clemson Univ., SC. Dept. of Agricultural Engineering.
J. Zirschky, and L. Carlson.
Journal of the American Water Works Association, Vol. 76, No. 1, p 80-83, January, 1984. 4 Fig, 3 Tab, 8 Ref.

Descriptors: *Overland flow, *Iron removal, *Potable water, Water treatment, Groundwater, Heavy metals, Iron, Water reclamation, Chemical degradation.

Overland flow, an effective wastewater treatment process, can be used for potable water treatment. Many groundwaters contain excessive amounts of ferrous iron that result in a water of poor aesthetic quality. The natural reaeration that occurs during overland flow oxidizes ferrous iron to the more insoluble ferric form. The resulting precipitate then settles on the slope. An existing overland flow treatment system in Salo, Finland, achieves 97% iron and manganese removal. The system has a capacity of 1ML/d. Iron-bearing groundwater is discharged at the top of a 100-m long, 17-degree, natural slope. At the bottom of the slope, the water infiltrates into sand and gravel recharge basins where any remaining iron precipitate is filtered from the runoff. There are few mechanical systems to require maintenance, supervision or energy. Removal of the precipitate from the surface of the recharge basins is required only once a year. (Murphy-IVI)
W84-03143

THE OCCURRENCE OF ALUMINUM IN DRINKING WATER,
R. G. Miller, F. C. Kopfler, K. C. Kelty, J. A. Stober, and N. S. Ulmer.
Journal of the American Water Works Association, Vol. 76, No. 1, p 84-91, January, 1984. 6 Fig, 13 Tab, 16 Ref.

Descriptors: *Aluminum, *Drinking water, Potable water, Groundwater, Surface water, Water quality, Raw water, Municipal water, Coagulation, Iron, Alum.

Raw and finished water samples were collected from 186 water utilities five times throughout a year and analyzed for iron and aluminum content. The water samples were categorized by the supply source (ground, surface, or a combination of both), the type of water (raw, finished, or untreated distribution samples), and the type of coagulation used in the treatment process (aluminum sulfate, ferric chloride, other coagulants such as cationic polymers, or no coagulant). The samples were also categorized according to the 10 EPA regions and 4 population categories. In the few facilities that used iron as a coagulant, the concentrations of iron and aluminum decreased. When alum is used for coagulation, there is a 40-50% chance that the concentration of aluminum will increase above the original concentration in raw water. Aluminum is also more likely to exist in surface waters than in groundwaters. (Murphy-IVI)

CONTROL OF TRIHALOMETHANE PRECURSORS IN DRINKING WATER: GRANULAR ACTIVATED CARBON WITH AND WITHOUT PREOZONATION,
Louisiana Tech Univ., Ruston.
W. H. Glaze, and J. L. Wallace.
Journal American Water Works Association, p 68-75, February 1984. 15 Fig, 4 Tab, 20 Ref.

Descriptors: *Drinking water, *Trihalomethanes, Preozonation, Ozonation, Granular activated carbon, Water quality control, Water treatment.

In a pilot study that lasted 80 weeks, unozonated and ozonated waters were fed to granular activated carbon columns to compare the removal of trihalomethane formation potential by GAC treatment with that by ozone-GAC treatment. The results were comparable for these treatments. Preozonation before GAC adsorption did not have a dramatic effect on the removal of THM precursors, at least at the dosages used in this study, generally 2-3.5 mg/liter. The GAC columns outperformed the ozone-GAC systems in terms of cumulative TOC or THMFP removed. In terms of percentage removal, however, the two trains performed almost identically. Natural organics were slightly less adsorbable and slightly more biodegradable after ozonation, making the ozone-GAC systems and GAC systems perform nearly the same. Optimization of the ozone dosage and the GAC reactivation regime should lead to enhanced microbiologic removal, which would extend the lifetime of GAC for THMFP removal. (Baker-IVI)

RELATIONSHIP OF NITRATE CONCENTRATIONS TO DISTANCE OF WELL SCREEN OPENINGS BELOW CASING WATER LEVELS,
Geological Survey, Lawrence, KS. Water Resources Div.
T. B. Spruill.
Water Resources Bulletin, Vol. 19, No. 6, p 977-981, December, 1983. 3 Fig, 2 Tab, 13 Ref.

Descriptors: *Nitrates, *Well water, *Kansas, Well screens, Depth, Groundwater pollution, Unconsolidated aquifers.

Data from 54 wells in central and eastern Kansas developed in unconsolidated deposits of Quaternary age indicate that nitrate concentrations are inversely related to the depth of the well screen opening below the water level in the well casing. Because this relationship was found to exist in an area of Nebraska and in a large area of Kansas, the relationship is generally valid over a wide geographical area. In addition, the data indicate that the incidence of nitrate concentrations exceeding 45 mg/l and nitrate concentrations, in general, are significantly lower in water from wells with screens deeper than 25 ft below the water table in unconfined aquifers or where screens are placed in deep confined aquifers. No concentrations of nitrate greater than 45 mg/l were in observed wells where screens were deeper than 60 ft below the casing water level. Placement of well screens as far below the water table as possible in unconfined unconsolidated aquifers in Kansas, and possibly other areas of the Midwest, may be an effective measure in preventing undesirable nitrate concentrations in ground water supplies, particularly in areas where nitrate is a problem. 5G. Water Quality Control

TROUT-ZOOPLANKTON RELATIONSHIPS IN MEDICAL LAKE, WA, FOLLOWING RESTORATION BY ALUMINUM SULFATE TREATMENT,
Eastern Washington Univ., Cheney. Dept. of Biology.
S. M. Knapp, and R. A. Soltero.
Journal of Freshwater Ecology, Vol. 2, No. 1, p 1-12, March, 1983. 5 Fig, 3 Tab, 17 Ref.

Descriptors: *Trout, *Fish food organism, *Medical Lake, *Washington, *Lake restoration, *Aluminum sulfate, Eutrophic lake, Fish establishment, Trout farming, Lake fisheries, Water quality control.

After restoration by whole-lake applications of liquid aluminum sulfate, Medical Lake, Washington, received a total planting of approximately 31,000 fingerling rainbow trout (Salmo gairdneri) from 1978 to 1980. Prior to treatment the lake had been unable to support game fish. Post-treatment improvement in water quality and zooplankton standing crops permitted good trout survival and growth. Daphnia pulex comprised over 90 percent of the trout diet for most age classes and dominated the biomass of the 0+ age class. Size-selective predation was apparent for D. pulex 1.75 mm in length or larger. Intensive predation by trout appeared to be eliminating D. pulex as an available food source, which may jeopardize the effectiveness of the lake restoration as grazing on phytoplankton standing crop might diminish. ADMINISTRATION LOSES ITS UMBRELLA AGAINST STANDFAST ACID RAIN POLICY,
L. Mosher.
National Journal, Vol. 15, No. 31, p 1590-1591, July, 1983. 1 Fig.

Descriptors: *Acid rain, *Political aspects, Legislation, Federal jurisdiction, Governmental interrelations, Legal aspects, Sulfur dioxide, Nitrogen oxides, Auto emissions, Exhaust.

On June 27, 1983, a group of nine nationally known scientists urged action be taken against acid rain, arguing that the risk of further environmental damage far outweighted the risk of acting on limited information, and that some of the information which had been requested by the government could never be supplied as the measurements needed for that information were not in use decades ago. A very major concern was over continuing damage to soil microorganisms caused by sustained acidification. However, response was slow in coming to this report. One basic problem is to determine how much sulfur dioxide emissions to reduce and where. Acid rain bills on Capitol Hill fall into three categories: those calling for more research, for reductions in sulfur dioxide emissions in the 31 state bordering on or east of the Mississippi River and for reduction of both sulfur dioxide and nitrogen oxides in all 48 states. There appears to be in increased political momentum building to support efforts to control acid rain. (Baker-IVI)

POSSIBLE MEASURES FOR THE RESTORATION OF LAKE SEMPACH (MOGLICHE MASSNAHMEN ZUR RESTAURIERUNG DES SEMPACHERSEES),
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
R. Gachter, D. Imboden, H. Buhrer, and P. Stadelmann.
Schweizerische Zeitschrift Hydrologie, Vol. 45, No. 1, p 246-266, October, 1983. 13 Fig, 3 Tab, 14 Ref.

Descriptors: *Lake restoration, *Phosphorus, *Switzerland, *Lake Sempach, Hypolimnion, Aeration, Siphoning, Primary productivity, Wastewater treatment, Pollution load.

Lake Sempach is situated in the central part of Switzerland some 15 km NW of Lucerne. Since 1954 average orthophosphate and total phosphorus concentrations have increased twenty and eightfold respectively in Lake Sempach. As a consequence of increased primary production, pH values, supersaturation of oxygen, and differences in alkalinity between winter and summer increased in the epilimnion. The construction of wastewater purification plants which started in 1968 was insufficient to reduce the total phosphorus loading, although in 1977 58% of the population was connected to wastewater treatment plants. The lake is not in steady state with its phosphorus loading and the net deposition rate of phosphorus is not linearly related to the phosphorus content of the lake. This implies that linear steady state one-box models are unsuitable to describe the phosphorus balance of this lake. To estimate the effects of decreasing the phosphorus loading, hypolimnion aeration or hypolimnion siphoning, a nonlinear dynamic lake model is used. The model predicts that the defined water quality goals can only be achieved within the next 15 years if the external phosphorus loading is reduced by at least 50% and simultaneously lake-internal measures, such as hypolimnion aeration or hypolimnion siphoning are carried into effect. Siphoning is recommended in preference to aeration since this lake-internal measure requires much less energy and maintenance. (Moore-IVI)

WHAT PRICE AN UMBRELLA FOR ACIDIC RAIN,
P. Capes.
Process Engineering, Vol. 64, No. 5, p 29, 31-32, May, 1983. 1 Fig, 1 Tab.

Descriptors: *Acid rain, Sulfur dioxide, Industrial wastes, Powerplants, Water pollution control, England, Scandinavia, Fuels, Desulfurization.

As the principal source of atmospheric sulfur dioxide in the United Kingdom, it is likely that power stations would have to bear the brunt of any emission cuts resulting from current international discussion. The head of the CEGB's environmental section points to the absence of unequivocal evidence to suggest that the effects on Scandinavian forests are directly associated with sulfur dioxide emissions. The weight of the issue going against the CEGB is reviewed. To cut its own emissions by 30%, the CEGB would need to convert six fossil fuelled stations. Overall United Kingdom reductions of 30% would require that the Board convert a further four stations. Flue gas desulfurization, however, is not the only option available to CEGB. Pre-combustion washing of selected types of steam coal, selective importation of low-sulfur oil fractions are all possibilities. (Baker-IVI)

USE OF DISSOLVED OXYGEN MODELING RESULTS IN THE MANAGEMENT OF RIVER QUALITY,
Geological Survey, Reston, VA.
D. A. Rickert.
Journal of the Water Pollution Control Federation, Vol. 56, No. 1, p 94-101, January, 1984. 8 Fig, 2 Tab, 14 Ref.

Descriptors: *Water quality control, *Dissolved oxygen, *Model studies, Management, Planning, Water management, Willamette River, Oregon, River flow.

The dissolved oxygen (DO) regime was examined in the Willamette River, Oregon from 1973-1974 during which time a mathematical model was calibrated, verified, and used to project the effects on DO of a wide range of pollution loadings and flow conditions. Future achievement of DO standards in the Willamette River will require continued augmentation of summer low flows in addition to pollution control. Point-source loading of ammonia is the major cause of oxygen depletion in the modeled segment of river. Although DO levels in Portland Harbor are currently above the state standard, removal or partial reduction of a localized benthic demand would improve summer DO concentration. BOD loading from municipal wastewater treatment plants presently exerts a relatively small impact on DO. For the foreseeable future, there is no need for municipal, advanced waste treatment to protect DO levels in this river. Maintenance of a minimum low flow of 170 cubic meters/second and reduction of industrial ammonia loading are the important management needs. (Baker-IVI)

PTIMIZATION OF A TREE-LIKE WATER-UPPLY SYSTEM,
Edok-Eter-Mandilas Ltd., Athens (Greece).
. J. Kareliotis.
ournal of Hydrology, Vol. 68, p 419-429, 1984. 2 ig, 5 Tab, 4 Ref.

Descriptors: *Optimization, *Water conveyance, Systems analysis, Optimum development plans, Resources development, Planning, Water supply, Cost analysis.

The construction of water-supply schemes involves significant amounts of capital investment and therefore their planning in selecting the optimum layout constitutes a very important part in the process between their conception and the final execution of the project. An optimization method for the design of a tree-like water-supply system is presented. The system is divided into stages for a dynamic programming formulation and the state variables are defined to be pipe piezometric heads. The separation into stages is such that, for a given state, the optimum return is determined by applying linear programming. The optimum is defined as the minimum total cost of the system. The total cost consists of the cost of pumping equipment, pumping, storage reservoirs and the cost of pipes which can vary according to the pressure strength requirements. The developed approach is applied to an example water-supply system, where the estimate of the minimum total annual cost of the system is the objective. The example system solved and its dynamic programming formulation had a serial structure. Other systems with more than one source and/or elevated tanks and booster stations not in a series can be treated similarly by applying the dynamic programming technique for nonserial systems. The computation of the optimum for any given system can be performed very rapidly when a general linear programming program is available, since a computer solution of the mathematical equation of dynamic programming is not a difficult task. (Baker-IVI)
W84-03353

SOME MATHEMATICAL PROBLEMS IN OPTIMIZED PLANNING OF A WATER-RESOURCES SYSTEM,
East China Technical Univ. of Water Resources, Nanjing. Dept. of Hydrology.
Y. Bingru.
Journal of Hydrology, Vol. 68, p 431-442, 1984. 4 Fig, 5 Ref.

Descriptors: *Optimization, *Water resources development, Systems analysis, Planning, Mathematical equations.

The optimized planning of a water-resources system is usually carried out through constructing a mathematical model of the system, and is solved by systems analysis or methods of mathematical programming. For a general deterministic linear programming problem, the constraint condition usually consists of three types, viz. two kinds of inequality equations, and another of equality constraints. In solving such a problem with the Simplex method, usually some relaxation variables are introduced in order to find the initial feasible basic solution, as well as to reduce the mathematical model having inequality constraints, to the standard form of LP. A general method of generating the non-inferior set in multi-objective programming is also proposed. The idea of using the two-dimensional decomposition method is discussed and numerical examples are given for illustration. (Baker-IVI)

RURAL WATER-SUPPLY AND SANITATION PLANNING: THE USE OF SOCIOECONOMIC PRECONDITIONS IN PROJECT IDENTIFICATION,
CDM-WASH Project, Arlington, VA.
D. B. Warner.
Journal of Hydrology, Vol. 68, p 443-459, 1984. 2 Fig, 16 Ref.

Descriptors: *Planning, *Water supply development, *Sanitation, Rural areas, Socioeconomic factors, Developing countries.

Recognition of the socioeconomic preconditions for successful rural water-supply and sanitation projects in developing countries is the key to identifying a new project. The socioeconomic aspects of preconditions in the context of a five-step procedure for project identification are discussed. The procedure includes problem identification, determination of socioeconomic status, technology selection, utilization of support conditions, and benefit estimation. While the establishment of specific preconditions should be based on the types of projects likely to be implemented, a number of general relationships regarding favorable preconditions in water and sanitation planning are outlined. These relationships are used within the five step procedure to develop a set of general guidelines for the application of preconditions in the identification of rural water-supply and sanitation projects. (Baker-IVI)

A BINARY STATE DP ALGORITHM FOR OPERATION PROBLEMS OF MULTIRESERVOIR SYSTEMS,
Syracuse Univ., NY. Dept. of Industrial Engineering and Operations Research.
M. Ozden.
Water Resources Research, Vol. 20, No. 1, p 9-14, January, 1984. 3 Fig, 1 Tab, 11 Ref.

Descriptors: *Operating policies, *Reservoirs, Algorithms, Mathematical studies, Management, Decision making.

Reservoir operation problems are complicated by the nonlinearities in the objective functions. The dynamic programing (DP) procedure is often used to solve this problem because of the sequential nature of the decisions involved, but for simultaneous operations of multireservoir systems, other DP-based techniques are frequently found to be more efficient in overcoming the curse of the dimensionality problem caused by the interdependencies of the decisions. The DP-based procedure proposed performs better than other well-known techniques. The applications of this technique are presented in two different formulations for four-reservoir operation problems. The convergence properties of the algorithm are investigated as revealed from the systematic solutions of a control problem with various dimensions. The procedure enables the solution of moderately large systems within a reasonable computation time for the operation of multireservoir systems. (Baker-IVI)

6B. Evaluation Process

THE ALTAMIRA HYDRO COMPLEX IN THE AMAZON REGION,
A. T. Duarte, J. L. Pettena, and J. da Rocha Paes Filho.
International Water Power and Dam Construction, Vol. 35, No. 10, p 23-28, October, 1983. 5 Fig, 5 Tab.

Descriptors: *Dam construction, *Energy, *Brazil, *Altamira Hydro Complex, Powerplants, Construction, Design criteria, Planning, Evaluation, Economic aspects.

Principal results are given of the Hydroelectric Inventory Studies of the Xingu river basin, in the Amazon region of Brazil. The potential for installed capacity was more than 20,000 MW at an average cost of about US$1000/kW, realized with a maximum of seven sites developed at various drops along the river. At the two downstream developments which constitute the Altamira complex, it is possible to develop more than 14,000 MW of installed capacity at a cost of about US$750/kW. The lack of centers for local consumption and the large amount of energy which can be produced from the hydrocomplex of Altamira, mean that the tendency will be to export this energy in the future to other regions in Brazil in need of supplies. Based on current estimates the transmission costs of energy generated at the complex for the three load factors considered in the preliminary studies reveal them to be very attractive as they do not exceed US$7/MWh. MAGAT RIVER MULTIPURPOSE PROJECT,
National Irrigation Administration, Quezon City (Phillipines).
B. V. Viola, and V. C. Wilhelm.
International Water Power and Dam Construction, Vol. 35, No. 12, p 17-23, December, 1983. 3 Fig, 4 Tab, 5 Ref.

Descriptors: *Dam construction, *Design criteria, Flood control, Magat River, Philippines, Water resources development, Planning, Decision making, Evaluation, Typhoons, Earthquakes.

Basic design considerations, construction methods and the principal features of the Magat multipurpose development in the Philippines are discussed. The system will irrigate 102,000 ha of ricelands and generate 360 MW of power. Several factors played an important role in determining the location and the basic features of the Magat project. Bagabag, a large town in the potential reservoir area with a population of over 30,000 was, by government decision, not to be moved, thus restricting the elevation. High sedimentation rates called for extra storage to maintain the useful life of project. Other factors included the high seismicity of the area and the very high flood runoffs. Since the dam site itself is traversed by several faults which are considered potentially active, the structures had not only to be designed for high ground acceleration, but also for possible offset conditions. The Magat watershed is adjacent to the Baguio meteorological station. Typhoons create almost unbelievable runoffs and the Magat river, which at the dam site has an average flow of about 200 cu m/sec, has experienced a flood flow of 20,000 cu m/sec. The maximum inflow should be in the order of 34,500 cu m/sec. A spillway design capacity of 30,800 cu m/sec was planned. (Baker-IVI)

DEVELOPMENT OF WATER RESOURCES IN KOREA,
Industrial Sites and Water Resources Development Corp., Seoul (Korea).
J. C. Kim.
International Water Power and Dam Construction, Vol. 35, No. 12, p 23-25, December, 1983. 3 Fig, 3 Tab.

Descriptors: *Water resources development, *Dam construction, *Korea, Reviews, Water demand, Energy, Powerplants, Chungju Dam, Environmental effects, Government supports.

Korea has built enough dams to store 20% of the annual average runoff during the past 20 years. The Korean agriculture is based primarily on rice. Farmers begin planting in early April and harvest in October. Traditionally Koreans built small ponds and earth dams near their paddy fields so that the storage might cover the dry season for three months from April through June. Things began to change in 1945 with the Japanese invasion of Korea. The Japanese built higher earth dams so as to grow more rice for export to Japan and they began building high concrete dams incorporating hydro powerplants to provide industries with energy for manufacturing strategic materials for invading China. After the Korean war the country could not afford large investments in exploiting water power. A shift from light industry to heavy chemical manufacture in the 1960s brought about a power shortage and an increase in the demand for

water. South Korea has a total land area of about 99,000 sq km and an average annual precipitation of 1160 mm yielding a potential water resource of 114 x 10 to the 9th power cu m. Plans are underway to build the Chungju multipurpose dam, 97.5 m high with a storage capacity of 2.75 x 10 to the 9th power cu m bringing the current total storage capacity to 13.1 x 10 to the 9th power cu m. Environmental protection is being emphasized by the government and the government now requires an environmental survey before any civil engineering project is undertaken. (Baker-IVI)

A TIME SERIES APPROACH TO FORECASTING ANGLING ACTIVITY AT A RECREATIONAL SITE BASED ON PAST SUCCESSES,
Minnesota Univ.-Duluth. Dept. of Economics.
D. N. Steinnes, and R. L. Raab.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 12, p 2189-2193, December, 1983. 2 Tab, 8 Ref.

Descriptors: *Time series analysis, *Forecasting, *Recreation, *Fishing, Fish management, Conservation, Mathematical models, Model studies, Model testing, Regression analysis, Cost analysis.

A multiple regression model was developed for estimating or forecasting the impact of past fishing 'successes' on the current angling activity or participation at a recreational site. The time series methodology is useful as a forecasting tool by investigating the lag structure of success and measuring its elasticity. The evaluated empirical results were based on daily time series data for Lester River, a Lake Superior river. The river was surveyed in Duluth, Minnesota in 1977 during the spring steelhead run on a regular basis to collect a systematic sample of 33 days during 2 months. The anglers respond more to past total success at the site than to past success per unit of effort at the site. The model could be extended to estimate the economic value of catching a fish. An extended model would be part of a comprehensive approach for valuing changes in habitat by using benefit-cost analysis with it. (Murphy-IVI)

APPRAISING WASTEWATER DISCHARGE COMPLIANCE LEVELS,
Allied Chemical Corp., Morristown, NJ. Corporate Research Center.
E. J. Shields.
Pollution Engineering, Vol. 15, No. 7, p 33-37, July, 1983. 1 Fig, 3 Tab.

Descriptors: *Wastewater disposal, *Monitoring, Compliance, Water analysis, Planning, Management.

Appraisals made of the compliance performance of wastewater discharging facilities made to date have largely been qualitative in nature, consisting of subjective evaluations which frequently use non-precise terms such as serious, substantial and significant to describe the levels of non-compliance that exist. A more meaningful technique for evaluating the performance of a facility in maximizing the compliance levels achieved by their wastewater dischargers would provide management with a useful control tool. The technique should provide a uniform approach for appropriately weighing frequency of excursions, pollutant parameters involved, degree to which the discharge limitations are exceeded, duration of the excursions, and the exposure to excursions posed by the amount of required testing. A description of the Allied Chemical Program which uses such a technique is presented. (Baker-IVI)

NEW BUSINESS OPPORTUNITIES,
Lorenz (William T.) and Co., Boston, MA.
W. T. Lorenz.
Pollution Engineering, Vol. 25, No. 9, p 32-36, September, 1983.

Descriptors: *Wastewater treatment, *Economic aspects, *Water treatment, Business opportunities, Management, Decision making, Planning, Financial aspects, Instrumentation, Water resources development.

New business opportunities in the water field are developing including those related to the following areas: water resource planning, development of resources, water treatment, wastewater treatment, wastewater reuse and recycling, transmission and storage, instrumentation, the agricultural market, the government market, the industrial market and the private market. Package wastewater treatment plants have gained a strong foothold in the complex area of industrial wastewater treatment. There are about 100 United States companies supplying such equipment and the competition is fierce in this aspect of water treatment. The total wastewater and water instrumentation market in 1985 is expected to reach $325 million. (Murphy-IVI)

CONTROLLING AGRICULTURAL SOIL LOSS IN ARKANSAS' NORTH LAKE CHICOT WATERSHED: AN ANALYSIS OF BENEFITS,
Arkansas Univ., Fayetteville. Dept. of Agricultural Economics and Rural Sociology.
C. T. Osborn, and R. N. Shulstad.
Journal of Soil and Water Conservation, Vol. 38, No. 6, p 509-512, November-December, 1983. 2 Fig, 8 Ref.

Descriptors: *Erosion control, *Cost-benefit analysis, Water management, Recreation, Lakes, Financial aspects, Mathematical equations, Lake Chicot, Arkansas.

A unique environmental situation made it possible to estimate the recreational benefits of a soil erosion control project in the northern watershed of Lake Chicot, Arkansas. Using a discount rate of 7 and 3/8%, the estimated present value of benefits for the project over a 50 yr period is $67.7 million. Compared with the estimated present value of costs over the same period, $600,000, it is clear, at least from an efficiency standpoint, that the proposed soil erosion control project is overwhelmingly justified. Lake Chicot is, in reality, two lakes, side-by-side, separated by a man-made levee. The southern lake had become silty and turbid, drastically diminishing its recreational value. The purpose of the erosion control program was to prevent the same loss of recreational value in the north lake. Mathematical equations were developed relating hours per visit to travel cost, on-site cost, income, investment in recreational equipment, number of visits per year, number in parts, and age. These equations were developed for each basin of the lake. When all the information was gathered, dividing the present value of benefits for the program by the present value of costs yields a benefit-cost ratio of 112, which clearly justifies the undertaking of the proposed soil erosion control program. (Baker-IVI)

PROVIDING WATER SUPPLIES AND SANITATION FOR THE DEVELOPING WORLD,
R. Birenbaum.
Water and Pollution Control, Directory and Buyers' Guide, Vol. 121, No. 6, p 20-25, November, 1983. 4 Fig.

Descriptors: *Water supply, *Developing countries, *Sanitation, Wastewater, Drinking water, Planning, Evaluation, Decision making, Public health.

The United Nations declared the 1980s to be the International Drinking Water Supply and Sanitation Decade in which the goal was to provide safe drinking water and adequate sanitation to all people by 1990 for reasons of public health. A WHO survey listed manpower and finances as the two greatest restraints to meeting the goal. Canadian consultants who have started work overseas understand that the commitment to devising and maintaining high quality sanitation and water supply systems in a developing country requires trained personnel. One major problem area lies in the training of local personnel in the maintenance of whatever improvements are made. The installation of shiney new equipment is not necessarily the only nor the best answer to the problems that exist in these developing nations. (Baker-IVI)

CLEANER TECHNOLOGY: WHO GAINS FROM POLLUTION PREVENTION,
J. Elkington.
Process Engineering, Vol. 64, No. 5, p 24-26, May, 1983. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Industrial wastes, *Planning, Water pollution prevention, Management, Decision making.

The current status of clean technology is reviewed. Responses to a major industrial pollution problem include doing nothing and allowing the problem to continue unabated, closing the factory or plant, continuing discharging but in such a way that pollution is minimized, installing pollution control systems to remove the pollutants, develop and deploy cleaner and low waste technologies, and promote structural changes in the local, regional, or EEC economy. Last year the first batch of United Kingdom entries joined the UN Economic Commission for Europe's Compendium on Low and Non-Waste Technologies. The challenge is for Government and for the public sector agencies to ensure that the appropriate technologies are made available, by whatever route, to medium and small companies. (Baker-IVI)

MISSOURI RIVER - THE NEW COMPACTING GAME,
M. E. Harris.
Water Resources Bulletin, Vol. 19, No. 6, p 921-927, December, 1983. 4 Tab, 19 Ref. Northwest Area Foundation grant 785-0144A.

Descriptors: *River basins, *Water use, Missouri River, Interstate agreements, Water management, Water demand, Water resources development.

Proposed interbasin water diversions of the Missouri River are related to energy development, agricultural, municipal, and industrial water use. Overall, an estimated 8.5 million acre-feet of water from the Missouri River could be diverted by the year 2000 if three major projects are allowed to take place or continue. Interstate issues in the river basin include interbasin water diversions, riverbed and shoreline degradation, loss of recreational and natural areas, reduction in navigation capacity, the status of the Pick-Sloan Missouri Basin Program in terms of general river development, and the elimination of river basin commissions. An attempt to develop a comprehensive interstate water compact failed in the 1950s. Much of the concern over general river development lies in differing individual state attitudes towards the Pick-Sloan Missouri Basin Program. But, there are other available mechanisms for the resolution of the current political and legal differences among the ten river basin states. (Murphy-IVI)

FUNDING MUNICIPAL WASTEWATER FACILITIES IN GEORGIA,
J. L. Ledbetter, J. C. Dozier, and W. K. Jordan.
Current Municipal Problems, Vol. 10, No. 2, p 206-212, Fall, 1983. 1 Tab.

Descriptors: *Grants, *Wastewater treatment facilities, Georgia, Economic aspects, Water pollution control, Industrial wastes, Municipal wastewater, Clean Water Act, Government finance, State jurisdiction, Construction Grants Program.

The Clean Water Program in Georgia is reviewed and updated. The principal sources of water pollution in that state are industries and publicly owned wastewater treatment works, with the latter being the more difficult to control, due more to lack of sufficient funds than to technical problems. The State has received about $610 million over the ten year history of the Construction Grants Program. There are approximately 67 wastewater treatment facilities that have been completed and were upgraded or totally constructed with monies appropriated under the Clean Water Act (PL 92-500). Additional funds are needed to insure that the momentum which has built up in the program will be maintained. However, serious reductions in funding levels for the State have made it clear that many of the communities currently invovled in planning and design activities may never receive funding for the actual construction of needed facilities through the Construction Grants Program. ESTIMATING DEMAND FOR INTAKE WATER BY SELF-SUPPLIED FIRMS,
Arkansas Univ., Fayetteville. Bureau of Business and Economic Research.
J. A. Ziegler, and S. E. Bell.
Water Resources Research, Vol. 20, No. 1, p 4-8, January, 1984. 3 Tab, 30 Ref.

Descriptors: *Water demand, *Pricing, Water supply, Industrial water, Water use, Statistical analysis, Economic aspects.

In many instances, heavy water-using firms use water from a self-supplied source such as a nearby lake, river, or well and do not purchase it from any private or public source. While these firms pay for the acquisition, treatment, and disposal of water, they do not pay a price determined in the market through the interaction of independent buyers and sellers but rather a price which reflects only firm costs and demands. The idea that there is no significant difference in the estimates of industrial water demand schedules when using either average or marginal cost as a proxy for price was examined. Water usage and cost information were obtained from questionnaires sent to paper and chemical plants in Arkansas, and two demand functions for intake water were calculated. F tests were performed to determine if each price variable made a significant contribution to its respective model. In addition, adjusted R(2), Mallow's statistic, and the PRESS statistic were calculated to determine best statistical fit and predictive capability. The findings indicated that both price variables made statisically significant incremental contributions to their respective models but that the model using AC explained a larger percentage of variance about the mean and was a better predictor. This relationship may change in the future as water becomes relatively more expensive and a larger part of total production costs. These circumstances may result in firms becoming more responsive to marginal water costs. (Baker-IVI)

6D. Water Demand

U.K. PUSHES R AND D TO MEET POTABLE WATER DEMAND,
J. Lock.
Consulting Engineer, Vol. 61, No. 5, p 72-73, November, 1983.

Descriptors: *Water supply development, *United Kingdom, *Potable water, *Water demand, Nitrates, Organic compounds, Lead, Drinking water, Plumbing, Water quality control.

Problems in the United Kingdom concerning water are similar to those in the United States: new towns and industrial estates must be supplied with water, and, simultaneously, old systems must be replaced or repaired. Public concern in the United Kingdom is mounting over trace organics and inorganics in the water supplies. Lead in potable water is a risk for the estimated 40% of the British people who still have lead plumbing. Nitrate concentrations in ground and surface waters are increasing. The total supply itself was shown to be a quickly reduced to a dangerously low level following the summer drought in 1976. Efforts are underway to increase the supply. (Baker-IVI)

CASCADE MODEL OF MONTHLY MUNICIPAL WATER USE,
Texas Univ. at Austin. Dept. of Civil Engineering.
D. R. Maidment, and E. Parzen.
Water Resources Research, Vol. 20, No. 1, p 15-23, January, 1984. 5 Fig, 2 Tab, 28 Ref. Texas Dept. of Water Resources contract 14-10044.

Descriptors: *Water use, *Municipal water, Mathematical models, Climate, Seasonal variation, Autocorrelation, Probability, Canyon, Texas.

A time series model of monthly municipal water use is formulated as a set of equations representing the effects of four factors on water use: trend, seasonality, autocorrelation, and climatic correlation. The parameters of these equations are found by passing the water use time series through a cascade of four transformations; in each transformation the parameters of an equation associated with one factor are statistically determined and the series transformed to remove the effects of this factor. After the last transformation, only a random error series remains. Monthly municipal water use at Canyon, Texas, from 1961-1978 is modeled as an example. The model explains 86% of the variance of this series, divided among the four factors as trend (29%), seasonality (44%), autocorrelation (2%), and climatic correlation (11%). The random error is shown to be normally distributed by a nonparametric procedure characterizing probability families by their density quantile functions. (Author's abstract)

6E. Water Law and Institutions

FISHING RIGHTS: INDIAN FISHING RIGHTS AND CONGRESS: THE SALMON AND STEELHEAD CONSERVATION AND ENHANCEMENT ACT OF 1980,
J. P. Mentor, Jr.
American India Law Review, Vol. 9, No. 1, p 121-134, 1983. 94 Ref.

Descriptors: *Fishing, *Legal aspects, *Indian fishing rights, *Salmon, *Steelhead, Commercial fishing, Sport fishing, Pacific Northwest.

The Salmon and Steelhead Conservation and Enhancement Act of 1980 was passed to prevent the depletion of the salmon and steelhead resource of the Pacific Northwest. However, the act leaves unresolved the status of commercial fishing for steelhead, and thus does little to ease the tension between Indians and non-Indian sports fishermen. The Act does not preclude future abrogation of Indian treaty fishing rights. The Act establishes a coordinated, comprehensive management entity, the Salmon and Steelhead Advisory Commission, provides funding for both state and tribal enhancement projects, and provides for the purchase of non-Indian commercial fishing and charter vessels and their licenses by the state. The most significant contribution of the Act is the adoption of a comprehensive management plan. (Baker-IVI)

THE THIRD WAVE IN WATER QUALITY MANAGEMENT,
R. J. Foxen.
Civil Engineering, (New York), Vol. 53, No. 4, p 43-45, April, 1983.

Descriptors: *Cost-benefit analysis, *Tertiary wastewater treatment, *Water quality management, *Water law, *Future planning, Capital costs, Cost analysis, Benefits, Secondary wastewater treatment, Water quality control, Water quality standards.

In the 1970's, there was great public pressure on the Environmental Protection Agency (EPA) to clean up water polluting discharges by methods of advanced wastewater treatment (AWT), no matter what the cost. In response to this pressure, Congress passed the Clean Water Act in 1972, which fostered adoption of AWT technology to improve water quality. A review of some AWT projects of the 1970's showed that some of them were not very cost effective. EPA funding was subsequently denied for some projects that would do little to improve water quality but would require great capital expenditures. Many groups have questioned the legality of AWT project reviews, stating that environmental impact and not cost savings should be the area of major concern. An amendment to the Act in 1966 (301h) allowed less than secondary treatment to marine wastewater discharges if it could be proven that minimum water quality standards would not be violated. In the early 1980's, increased demands to lessen government spending and increased burdens on taxpayers caused decreased local funds to finance AWT projects. The 301h waiver could be used in the future to meet minimum water quality standards in certain areas and provide more stringent AWT requirements only in areas where needed to promote economic efficiency by better use of public funds. (Geiger-FRC)

SPORHASE V. NEBRASKA EX REL. DOUGLAS: A CALL FOR GROUND WATER LEGISLATION,
J. M. Crane.
Denver Law Journal, Vol. 60, No. 4, p 631-643, 1983. 124 Ref.

Descriptors: *Groundwater, *Legal aspects, *Nebraska, *Legislation, Water export, Water import, Interstate commerce.

The Supreme Court, in its decision in the case of Sporhase vs Nebraska ex rel. Douglas, held that state water anti-export statutes are contrary to the commerce clause of the federal Constitution. This decision brings water regulations within the scope of the Court's previous pronouncements on state statutes regulating interstate commerce in animal, vegetable, and mineral resources. The development of the commerce power is outlined as it relates to state export/import restrictions, and the Court's rational in this decision in the context of

commerce clause precedent is examined. The Court's characterization of water is analyzed, and probable effects of this holding on future interstate water allocation plans will be projected. This comment takes the position that some state regulation of groundwater export is possible after Sporhase. (Baker-IVI)

WHEREVER THE WATER FLOWS: LYON APPLIES THE PUBLIC TRUST TO NON-TIDAL WATER,
B. Seldon.
Ecology Law Quarterly, Vol. 11, No. 1, p 21-45, 1983. 145 Ref.

Descriptors: *Public trust doctrine, *Land use, *Shores, Legislation, Legal aspects, California, Lakes, Rivers, Swamps, Wetlands.

Lands between high and low watermarks along the shores of all navigable water in California are subject to the public trust. Some of the land is subject to the public trust even though it was patented as swamp and overflowed land. Many of the lands subject to the trust have been filled or improved despite their trust status. The more equitable way to deal with these lands is to balance the interests of the public and the landowner on a case-by-case basis, as the California Supreme Court directed with tidelands in City of Berkeley. The uncertain nature of trust purposes and their tendency to conflict with each other lead to uncertain expectations among landowners affected by the public trust. Some of this uncertainty could be dispelled by regional planning, which would give each landowner an indication of what used he may make of his property without being found in conflict with a trust purposes. (Baker-IVI)

EQUITABLE DISCRETION UNDER THE FEDERAL WATER POLLUTION CONTROL ACT: WEINBERGER V. ROMERO-BARCELO,
California Univ., Berkeley. School of Law.
J. Petruzzi, and M. Thomas.
Ecology Law Quarterly, Vol. 11, No. 1, p 73-94, 1983. 192 Ref.

Descriptors: *Water pollution control, *Water Pollution Control Act, *Puerto Rico, Coastal waters, Equitable discretion, Legal aspects, Navy, Permits, Effluents.

Congress substantially amended the Federal Water Pollution Control Act (FWPCA) in 1972 to provide for a detailed permit system establishing individual compliance schedules for effluent discharge sources. United States Navy training in Puerto Rico has since 1970 been responsible for dumping much material into the coastal waters surrounding that island. Eventually the Supreme Court became involved in light of the statutory background of the FWPCA and case law concerning federal court exercise of equitable discretion. The text and legislative history of the Act require that a permit be obtained prior to the discharge of pollutants into navigable waters. In addition, previous Supreme Court decisions suggest that federal courts are without power to allow an ongoing violation of a statutory command. The Romero-Barcelo decision greatly changes the comprehensive regulatory program devised by Congress. That decision permitted the Navy to continue its discharges without a permit or a Presidential exemption. This decision may have the unfortunate consequence of encouraging violators of the Act to wait until they are sued before applying for a permit. (Baker-IVI)

MANAGING AGRICULTURAL POLLUTION,
Pennsylvania Univ., Philadelphia. Dept. of City and Regional Planning.
J. C. Keene.
Ecology Law Quarterly, Vol. 11, No. 2, p 135-188, 1983. 2 Tab, 327 Ref.

Descriptors: *Water pollution control, *Agriculture, Legal aspects, Legislation, Common law nuisance, Nuisance, Farm wastes, Land use.

Several major approaches to managing agricultural pollution are reviewed, including judicial resolution of land use conflicts based on principles of common law nuisance; recent legislative attempts to limit the application of those principles by the enactment of right-to-farm laws; technology-forcing regulation; and spatial separation of agricultural activities from land uses with which they conflict, by the creation of agricultural districts or comprehensive farmland protection programs. The essence of the law of private nuisance is that it involves the application of a set of general principles to a particular set of circumstances. The court must decide whether there is a substantial interference, whether the social value of one activity outweighs that of another, which of two uses is more appropriate for a particular neighborhood, and whether the harm can be either avoided or prevented at relatively little cost. The strengths of this process are that a landowner can do what he wants with his property so long as he does not interfere unreasonably with the rights of his neighbor, and that landowners can take advantage of developments in technology. (Baker-IVI)

SPORHASE V. NEBRASKA: THE MUDDYING OF COMMERCE CLAUSE WATERS,
California Univ., Berkeley. School of Law.
A. D. Greenberg.
Ecology Law Quarterly, Vol. 11, No. 2, p 215-239, 1983. 176 Ref.

Descriptors: *Legislation, *Ownership of water, Federal jurisdiction, Regulations, States rights, Water law, Water transfer.

The Sporhase opinion and the validity of state efforts to regulate interstate transfers of water are examined. Discussions center on the development of the state ownership exemption from Commerce Clause analysis, the Sporhase opinion, and the decision. In Sporhase, the Supreme Court attempted to balance the Commerce Clause goal of national unity with the traditionally strong local interest in water resource regulation. Water law is most efficient when made at the local level, and is a legitimate exercise of the police power of the state. Thus each state determines its own water rights doctrines with little interference from the federal government. Neither the presence of detailed state regulatory programs nor the importance of the resource justifies a departure from standard constitutional analysis. The Court can recognize the legitimacy of state water law by requiring all nonresidents to comply with standards a state establishes for its citizens. Resident preferences justified on the grounds of conservation and preservation goals invite the strictest scrutiny of the court. By implying that courts may decline this invitation when reviewing water laws, the Supreme Court in Sporhase provided little guidance to those who must draft and enforce such laws, and added confusion to an already unsettled state ownership doctrine. (Baker-IVI)

SO ITS NOT 'OURS' - WHY CAN'T WE STILL KEEP IT; A FIRST LOOK AT SPORHASE V. NEBRASKA,
Chicago-Kent Coll. of Law, IL.
A. D. Tarlock.
Land and Water Law Review, Vol. 18, No. 1, p 137-174, 1983. 121 Ref.

Descriptors: *Legislation, *States rights, Ownership of water, Federal jurisdiction, Regulations, Nebraska, Water transfer.

The United States Supreme Court's decision in Sporhase v. Nebraska is examined. The implications the decision has for western states' attempts to control their water resources are noted and a revision in the Court's approach to such questions is suggested. An approach is presented within the framework of Sporhase to export statutes that allows a state to assert its essential interests in determining the locus of water use. This effort is animated by the normative argument that there is no basis for federal preemption of state water law in this or any other energy issue. A process-based approach is suggested for western water law such that it suggests a case against judicial interference in water allocation choices when the risks of a malfunction in the political process are low. To continue to allow the states to allocate their water resources, courts need to avoid formulation too many hard and fast rules about the duty to share scarce waters among interested states. Existing principles of law provide a sufficient context for the political process to function to determine interregional equity issues. (Baker-IVI)

WETLANDS PRESERVATION, FISH AND WILDLIFE PROTECTION, AND 404 REGULATIONS: A RESPONSE,
Lewis and Clark Coll., Portland, OR. Natural Resources Law Inst.
M. C. Blumm.
Land and Water Law Review, Vol. 18, No. 2, p 469-489, 1983. 112 Ref. NOAA grant NA 81AA-D-00086.

Descriptors: *Legislation, *Permits, *Wetlands, *Wildlife, Water pollution control, Clean Water Act, Regulations, Economic aspects, Legal aspects.

The permit program established by section 404 of the Clean Water Act is defended against the charges of bureaucratic red tape and over-regulation. The value of wetlands and fish and wildlife are viewed as warranting a broad 404 jurisdictional mandate and a pluralistic review process designed to assure that the benefits of aquatic developments exceed their costs. It is argued that the existing 404 program, grounded on widespread intergovernmental and public review, has both preserved important ecosystems and produced more cost-effective developments. However, the wisdom and the legality of a recent expansion in the use of general permits is questioned and a number of suggestions to increase the effectiveness of the program are made. (Baker-IVI)
W84-03009

SPORHASE V. NEBRASKA EX REL. DOUGLAS: STATE CONTROL OF WATER UNDER THE CONSTRAINTS OF THE COMMERCE CLAUSE,
A. B. Tallmadge.
Land and Water Law Review, Vol. 18, No. 2, p 513-537, 1983. 157 Ref.

Descriptors: *States rights, *Legislation, *Groundwater, Ownership of water, Legal aspects, Nebraska, Commerce clause, Water transfer.

The Sporhase decision, for the first time, saw the Supreme Court declaring that groundwater is an article of commerce, and is therefore susceptible to congressional regulation. The Court further held that a Nebraska statute which prohibited the export of water to any state that did not provide reciprocal rights violated the commerce clause of the United States Constitution. This decision has prompted much anxiety in the western states causing some legislatures to consider new or amended water laws which will constitutionally justify restrictions on the use of water for interstate commerce. CONSTITUTIONAL LAW - WATER LAW - CONSTITUTIONALITY OF WATER EXPORT BANS AND LIMITATIONS ON INTERSTATE WATER ALLOCATION. SPORHASE V. NEBRASKA EX REL. DOUGLAS, - U.S. -, 102 S. CT. 3456 (1982),
J. Kelly.
Land and Water Review, Vol. 18, No. 2, p 553-573, 1983. 107 Ref.

Descriptors: *Legislation, *Water export, Water import, Legal aspects, Water supply development, Groundwater, Nebraska, Ownership of water, States rights, Federal jurisdiction, Water transfer.

n reviewing the Sporhase decision it may appear t first to cripple the states in their efforts to preserve and conserve scarce water resources. The Court's definitive characterization of ground water s an article of commerce clearly limits the states' power to regulate in this critical area, and at the ame time, opens the floodgates to ground water egulation by Congress. A closer look, however, eveals that state power to regulate ground water as not been severely curtailed. In fact, the Sporase Court recognized that the states should be afforded considerable latitude when drafting ground water legislation. As long as the states either refrain from implementing overly discriminatory legislation or are granted congressional authorization to do so, the Court indicated that it would continue to place substantial weight on state conservation interests. It may happen in the future that arid Western states may become net water importers to insure plentiful water supplies. The Court's emphasis on state interests and non-discriminatory legislation, as evidenced in this decision, is a victory for these states. (Baker-IVI)

NORTH DAKOTA CENTURY CODE SECTION 47-01-15: DETERMINING NORTH DAKOTA'S INTEREST IN THE BEDS OF NAVIGABLE WATERS,
M. G. Fiergola.
North Dakota Law Review, Vol. 59, No. 2, p 211-240, 1983. 208 Ref.

Descriptors: *North Dakota, *Navigable waters, *Ownership of beds, Riparian land, Public trust, Constitutional law, State sovereignty.

The State of North Dakota entered the Union on an equal footing with the original states and acceded to sovereignty over the beds of navigable waters within the state. The beds of navigable waters are sovereign public trust lands of the State of North Dakota. Because these beds are subject to the public trust doctrine, the State has a duty to protect the public interest in these lands. Nevertheless, the North Dakota Supreme Court has interpreted a state statute to grant that portion of the beds between the high and low water marks to riparians. Such an interpretation is contrary to a provision of the North Dakota Constitution, which prohibits the State from giving away state property. Therefore, the State of North Dakota should plead and the courts should address this ownership issue so that the public interest in the State's sovereign lands may be protected. (Moore-IVI)

SPORHASE V. NEBRASKA EX REL. DOUGLAS: DOES THE DORMANT COMMERCE CLAUSE REALLY LIMIT THE POWER OF A STATE TO FORBID (1) THE EXPORT OF WATER AND (2) THE CREATION OF A WATER RIGHT FOR USE IN ANOTHER STATE,
C. E. Corker.
University of Colorado Law Review, Vol. 54, No. 3, p 393-445, 1983. 179 Ref.

Descriptors: *Water rights, *State jurisdiction, *Groundwater, *Water export, *Nebraska, *Colorado, Overlying proprietor, Eminent domain, Commerce clause, Water management.

In the case of Sporhase v. Nebraska ex rel. Douglas, the U. S. Supreme Court ruled that a state statute which forbids export of groundwater to another state because the latter would deny reciprocity is unconstitutional. It is felt that the Court failed to understand the basic necessities, rooted in laws of the physical universe, which demand active local government management of water resources. The Court failed to articulate dormant commerce clause which can accomodate the diverse and local necessities of a federal union of continental size. Groundwater law, and its administration and management under government regulation is only one example of a problem that must be dealt with locally. Numerous cases are cited demonstrating water management decisions by state and federal agencies which affect inter-state water resources. Water is discussed here not as a commodity but rather as a management challenge requiring expert understanding of the geological implications and national concerns of managing this resource. (Wheatley-IVI)

TOWARD A UNIFIED REASONABLE USE APPROACH TO WATER DRAINAGE IN WASHINGTON,
G. C. Sisk.
Washington Law Review, Vol. 59, No. 1, p 61-85, 1983. 233 Ref.

Descriptors: *Reasonable use, *Drainage, *Washington, Legal aspects, Common enemy rule, Land use, Diversion.

Almost any development of land is likely to alter the flow of water draining from the land to the possible harm of neighboring property. Washington has traditionally applied both the common enemy doctrine allowing diversion of diffuse surface water drainage with impunity and a strict liability standard prohibiting injurious obstruction or diversion of watercourses and natural drains. A reasonableness doctrine applied consistently and uniformly to all drainage water however characterized, would provide recovery to landowners suffering from an unreasonable invasion of excessive water depriving them of the free use and enjoyment of their property. A reasonable use doctrine would balance the reasonableness of the defendant's conduct and use of land against the results of the harmful interference with the flow of both diffuse and channeled waters. It would be appropriate for the Washington legislature to adopt a unified standard of reasonableness for water drainage law. (Murphy-IVI)

THE POLITICS OF WETLAND CONSERVATION: A WILDLIFE VIEW,
K. W. Harmon, and C. A. McConnell.
Journal of Soil and Water Conservation, Vol. 28, No. 2, p 92-95, March-April, 1983. 2 Fig.

Descriptors: *Political aspects, *Policy making, *Wetlands, Conservation, Soil conservation, Water conservation, Legislation.

Political action at many levels plays a major role in the competition between public and private views of wetlands. In general, attitudes toward wetlands have changed in the past two decades, most noticeably at the federal level, less so in the states and locally. Of the many legislative efforts considered in this area, Section 404 has caused a significant amount of debate. However, attempts to undermine two decades of gains in balancing wetland protection with economic activity are not restricted to 404 and the Corps of Engineers. The US Department of Agriculture has retreated in its demands. The administration's resolve to resurrect a laissez-faire approach to management of finite resources is illustrated in its proposal to repeal the Principles and Standards for Planning Water and Related Land Resources and issue them as guidelines. (Baker-IVI)

MANAGEMENT OF GROUNDWATER THROUGH MANDATORY CONSERVATION,
M. J. Kelly.
Denver Law Journal, Vol. 61, No. 1, p 1-24, 1983. 131 Ref.

Descriptors: *Groundwater management, *Legal aspects, Overdraft, United States, Public rights, Pumping, Restrictions.

Groundwater overdraft is a serious problem in many parts of the United States. The prevailing common law and statutory groundwater property systems do not provide a satisfactory means of controlling groundwater overdraft. The introduction of constraints on pumpers may force existing groundwater users to reduce their pumping, but it would not constitute a taking requiring compensation. While there are precedents suggesting otherwise, application of such restrictions to existing groundwater users is not viewed as an illegal, uncompensated taking of private property. Both the public rights theory and more traditional takings theories support this result. The public rights theory holds that when uses of property have mutually incompatible spillover effects, the government can restrict either use without affording compensation. Under the diminution in value theory, the government is not required to compensate unless its restrictions on property cause such a large decrease in property value that the owner suffers total or near total economic loss. (Murphy-IVI)

WATER RIGHTS FOR EXPANDED USES ON FEDERAL RESERVATIONS,
Air Force Academy, CO.
K. S. Samelson.
Denver Law Journal, Vol. 61, No. 1, p 67-76, 1983. 73 Ref.

Descriptors: *Water rights, *National parks, Colorado, New Mexico, Forests, Parks, Prior appropriation, National Park System.

In November of 1982 the Colorado Supreme Court decided United States vs City and County of Denver, a leading case in the area of federal reserved water rights. The major issue addressed was the claim of the US for reserved water rights for national forests and national parks. Alternatives to the decision are explored from a legal and practical standpoint and a framework for resolving the conflict is presented. The dissent in US vs New Mexico asserted that the ruling denying additional reserved water rights for national forests with a 1960 priority date was dictum. The Colorado Supreme Court was of the opinion that that ruling was binding even if dictum. In the future the courts may realize that the leeway to grant additional water for federal reservations with expanded purposes exists. (Baker-IVI)

BASELINE DELIMITATIONS AND MARITIME BOUNDARIES,
Rhode Island Univ., Kingston. Center for Ocean Management Studies.
L. M. Alexander.
Virginia Journal of International Law, Vol. 23, No. 4, p 503-536, Summer, 1983. 8 Fig, 188 Ref.

Descriptors: *Legal aspects, *Boundaries, Boundary disputes, Water boundary, Law of the Sea, 1982 Convention, Coastal waters, State jurisdiction.

The official baseline along the coast is an important juridical feature of a state. The regulations for delimiting baselines are contained in articles 5 through 14 of the 1982 Convention. Although the articles have received general recognition as having the status of customary international law, certain ambiguities remain in the wording of some provisions. These ambiguities and apparent inconsistencies of action are explained and then baseline conditions are related to selected maritime boundary situations. (Baker-IVI)

6F. Nonstructural Alternatives

PRIVATE ENFORCEMENT OF FEDERAL ANTIPOLLUTION LAWS THROUGH CITIZEN SUITS: A MODEL,
D. A. Feller.
Denver Law Journal, Vol. 60, No. 4, p 553-571, 1983. 141 Ref.

Descriptors: *Water pollution control, *Public opinion, *Law enforcement, Legislation, Legal aspects.

The history of citizen suits brought directly against polluters provides little indication of how a continuous, organized program of litigation would fare as a public interest enterprise. The stage is set for a systematic attempt to privately enforce environmental statutes. The evolution of federal adminis-

trative machinery in support of those laws has created a store of discovery materials on which citizens may draw to identify and assemble cases. This is the cornerstone of any future private enforcement venture. The EPA reporting machinery facilitates selection of violations and significantly reduces the costs of discovery. The judiciary seems favorably disposed to the award of attorneys fees to plaintiffs bringing effective or useful citizen suits. Though it is impossible to state with any certainty that courts will allow all plaintiffs the full value of the fees and costs incurred in litigation, it is clear that courts are currently more willing to make such awards than at any time in the past. As a result, the financial deterrents are less threatening than in previous years. These favorable mechanical factors create the opportunity for an effectively organized and conducted private enforcement group to operate. (Baker-IVI)

WATER SUPPLY: A STATE OR LOCAL PROBLEM,
SCS Engineers, Inc., Reston, VA.
L. L. Guy, Jr.
Current Municipal Problems, Vol. 10, No. 2, p 200-205, Fall, 1983.

Descriptors: *Water supply, *State jurisdiction, *Local governments, Planning, Decision making, Management.

Problems in the municipal area of Washington, D.C. are briefly reviewed. Water supply development and protection is viewed in the main as a local responsibility and should not be given over to the federal government. Federal control seems to result in long delays. The easiest problems to solve are the technical ones. The most difficult appear to be the political ones. An agreement is presented which has been devised in Northern Virginia, building on the awareness of the local elected officials that only they could deal with the problems of adequate water supply. This agreement has four parts: regional cost and benefit sharing for the Bloomington Reservoir, regional sharing of the cost and benefits for the proposed Little Seneca Reservoir, a regional operating agreement directed by the Interstate Commission's CO-OP Computer Program to coordinate withdrawals from each of the reservoirs and the Potomac, and modifications to the existing Potomac low flow allocation agreement. (Baker-IVI)

A LAND-USE POLICY BASED ON WATER SUPPLY,
Wilson (Lee) and Associates, Inc., Santa Fe, NM.
L. Wilson.
Water Resources Bulletin, Vol. 19, No. 6, p 937-942, December, 1983. 1 Fig, 2 Tab, 2 Ref.

Descriptors: *Land use, *Policy, *Zoning, *Groundwater storage, Groundwater mining, Groundwater recharge, Lot size, Water use, Water supply development, Groundwater management, Santa Fe county, New Mexico.

Santa Fe County, New Mexico, has adopted a land-use policy in which zoning densities provide a balance between the water use on a parcel of land and the water supply available beneath that land. In two of four mapped hydrologic zones, ground water in storage will be allowed to be mined to exhaustion in 100 years (40 years in urban areas). Elsewhere, the policy is for a steady state with use balanced by recharge. Equations to determine storage or recharge can be solved using site specific data or regional estimates of hydrologic conditions. Substantial reductions in the lot size requirements are allowed if water conservation convenants are adopted. Public acceptance indicates that the policy successfully integrates technical and political concerns. It is simple to administer, yet reflects widely expressed public goals and values. (Author's abstract)

ASSESSING LAND-USE REGULATIONS IN COASTAL WETLANDS: THE CASE OF THE LONG POINT AREA, LAKE ERIE, ONTARIO,
British Columbia Univ., Vancouver.
S. Jessen, J. C. Day, and J. G. Nelson.
Coastal Zone Management Journal, Vol. 11, No. 1-2, p 91-115, 1983. 4 Fig, 6 Tab, 35 Ref.

Descriptors: *Coastal zone management, *Wetlands, *Land use, *Regulations, *Lake Erie, *Ontario, Planning, Permits, Floods, Erosion, Lake shores.

The Haldimand-Norfolk Region is subject to high potential coastal flooding and erosion hazards which pose severe management problems. The 1976 lakeshore regulation policy adopted by the Regional Municipality of Haldimand-Norfolk was aimed at directing development into areas less susceptible to flood and erosion hazards. This innovative strategy was initiated at the municipal level as a component of the regional land-use planning process. Determination of efficiency and effectiveness of the policy implementation process is based on analysis of permit approval files. All development applications submitted between 1976 and 1980 in the Turkey Point and Long Point Peninsulas are evaluated. Those areas, the most popular cottaging areas in the region, are most susceptible to flood and erosion hazards. Of the total applications submitted during the four-year study period, 37% were in these areas. The policy was ineffective and inefficient in controlling development in the two peninsulas. Applications were approved in the majority of cases, despite regulatory prohibition of developments in hazard-susceptible areas. A high percentage of applications involved some type of addition to existion infrastructures, such as extensions to buildings and addessory buildings. Such applications, while not creating new primary development, increased the potential loss as a result of flooding and erosion if approved. The time necessary to arrive at final decisions was lengthy, and the process was inefficient. The inefficiency may partially explain the ineffectiveness of the policy in controlling development. The lengthy delays encountered may have led many to apply for permits only after they had violated the regulations by constructing the proposed developments. (Moore-IVI)

6G. Ecologic Impact Of Water Development

THE 'DECADE OF THE ENVIRONMENT' IN THE U.S.S.R.,
San Diego State Univ., CA. Dept. of Geography.
P. R. Pryde.
Science, Vol. 220, No. 4594, p 274-279, April, 1983. 1 Fig, 36 Ref.

Descriptors; *Environmental protection, *Water pollution control, USSR, Russia, Seas, Industrial wastes, Industrial discharges, Lakes, Lake Baikal, Irrigation, Consumptive use, Water levels, Caspian Sea, Volga River.

The state of resource conservation and environmental protection in the USSR is examined as it stood at the beginning of the 1980's as compared to the early 1970's. Much environmental improvement took place over the past 10 years. Two economic events in the 1970's were responsible for some of the changes. First, there was a general downturn in what had been for three decades an unbroken and vigorous rate of industrial expansion. Second, there were worldwide energy crises in 1973 and 1979. A call was made for a more efficient use of natural resources. An increased emphasis on recycling, including that of municipal wastes, has thus taken place during the past 10 years. During the 1970-1980 decade attention was directed toward the Caspian Sea problem, Lake Baikal, poaching, land reclamation, and the broad topics of air and water pollution. An underlying reason for the gloomy outlook of many environmentalists in the USSR can be found in the decidedly utilitarian approach to the natural environment espoused by many senior Soviet planning officials and even academicians. Even after two decades of concern over Lake Baikal, the future of this vast resource of clean water is far from secure. Some steps have been positive. In most major cities primary treatment plants have been built and in some cases even secondary treatment facilities are available. Management of water quality and quantity in the Volga-Caspian basin has made progress. The reduction of the water surface level at the Caspian Sea due to the creation of upper basin reservoirs and lower basin irrigation projects has received attention, and progress is being made. A relatively newer issue of similar scope concerns the Sea of Azov. (Baker-FRC)

DUGOUTS IN EASTERN SOUTH DAKOTA: THEIR LOCATION IN RELATION TO BASIN WETLANDS AND STREAMS,
South Dakota Cooperative Wildlife Research Unit, Brookings.
K. B. McPhillips, L. D. Flake, W. A. Wentz, and R. L. Linder.
Journal of Soil and Water Conservation, Vol. 38, No. 5, p 434-436, September-October, 1983. 1 Fig, 2 Tab, 17 Ref. Federal Aid in Wildlife Restoration Program project W-75-R. South Dakota Agricultural Experiment Station project 7216-615. WRI project A-038-SDAK.

Descriptors: *Ponds, *Wetlands, *Environmental effects, Drainage, Dugouts, South Dakota, Streams, Drainage basins.

An estimated 55,855 dugouts existed in eastern South Dakota in 1976. About 77% of these were located in wetland basins or streams. An analysis of dugout location in reference to wetland class and wetland numbers relative to class suggests a need for recommendations on dugout placement to minimize effects of the structures on wetlands. Dugout location in relation to numbers of ephemeral, temporary, seasonal and semipermanent wetlands were most likely present in seasonal and semipermanent basins, followed by temporary and ephemeral ponds. The disruption of local natural hydrologic

gimes in the area of the dugout may be so tensive that wetland vegetation can no longer rvive outside of the dugout boundaries. Soil conrvationists, wildlife managers, and others who ake recommendations to landowners and others ould be cognizant of the potential problems in igout construction in wetlands. (Murphy-IVI)

HYDROELECTRIC DEVELOPMENT AND WILDERNESS CONFLICT IN SOUTH-WEST TASMANIA,
Australian National Univ., Canberra. Centre for Resource and Environmental Studies.
A. K. Dragun.
Environmental Conservation, Vol. 10, No. 3, p 197-204, 1983. 6 Fig, 5 Tab, 15 Ref.

Descriptors: *Hydroelectric development, *Wilderness, *Tasmania, *Australia, Environmental effects, Dams, Hydroelectric power, Cost analysis, Cost-benefits analysis, Alternative planning.

The hydroelectric developments planned for South-West Tasmania would inundate tracts having major wilderness and archaeological values as well as threaten a much larger area of wilderness. The development of the region is justified by the construction authority, in terms of an expected high rate of electricity demand towards the year 2000. A range of independent demand analyses suggest that the demand for electricity in Tasmania will not approach the Hydro-Electric Commission's expectations. Thus a lag in demand may be identified which should provide time for a rigorous evaluation of the wilderness value of the region together with an appraisal of the alternative electricity-generation options. A cost advantage exists for the favored 'Gordon-below-Franklin' project. The opportunity-cost differential of this project relative to several less-damaging alternatives is slight, at least when the growth in wilderness and electricity demands are considered. The opportunity-cost tradeoff appears quite trivial when current tourist and recreational impacts are accounted for. (Murphy-IVI)

HYDROBIOLOGICAL STUDY OF A HARNESSED RIVER: THE VERDON (ETUDE HYDROBIOLOGIQUE D'UNE RIVIERE AMENAGEE: LE VERDON LES LACS DE BARRAGE ET LES TRONCONS DE COURS D'EAU A DEBIT REGULE),
Direction de l'Equipement, Paris (France). Dept. of Sites, Environment and Information.
A. Gregoire.
Houille Blanche, No. 2, p 105-114, 1983. 6 Fig, 2 Tab, 23 Ref.

Descriptors: *Hydrobiology, *Dams, *Verdon River, Dam effects, Chemical properties, physical properties, Population dynamics, Hydraulics, Flow characteristics, Drainage, Trophic level, Ecological effects, Environmental effects.

The impact of five hydroelectric developments on the components of the ecosystem of a trout river (the Verdon) includes the conditions in reservoirs and the ecological problems specific to sections of streams with a regular flow. A study of the physical and chemical parameters of the water and the sediment in reservoirs ascertains the trophic potential of the environment. The follow up of the seasonal trend of the population of organisms corresponding to the main links of the food chain helps determine the trophic level of these reservoirs. The level of significance of the results for forecasting the change in the quality of water in other reservoirs, is assessed by appraising the relation of the five lakes of the Verdon to the French hydro-electric park. Measurement stations determine the respective impact of the dams on all the components of the ecosystem of the Verdon's flow by comparing mesological and biological structures. The most substantial influence is the change in natural hydraulic conditions. There are measures that can limit the nuisance caused by fluctuations in water level, ten yearly drainage, damming and make-up water. (Murphy-IVI)

MARINE LOG TRANSPORTATION AND HANDLING SYSTEMS IN BRITISH COLUMBIA: IMPACTS ON COASTAL MANAGEMENT,
Victoria Univ. (British Columbia). Dept. of Geography.
M. C. R. Edgell, and W. M. Ross.
Coastal Zone Management Journal, Vol. 11, No. 1-2, p 41-69, 1983. 4 Fig, 1 Tab, 27 Ref.

Descriptors: *Coastal zone management, *British Columbia, *Forestry, *Log handling, Log transport, Estuaries, Resources management, Lumber industry, Mariculture, Recreation, Fisheries, Harbors.

Over 90% of British Columbia's annual log harvest enters into complex water-based systems of transportation, storage, and handling. These systems have considerable impacts on a wide range of coastal resources and uses. A number of site-specific conflicts have arisen between forestry and pre-existing or emerging values including fisheries, mariculture, recreational boating, and harbor redevelopment. Specific data on the impacts leading to conflict are often fragmentary. However, concerns about highly valued and fragile areas, particularly estuaries, along with industrial concerns regarding log losses and handling efficiency, have prompted changes in log handling. These include moves to dryland sorting, log bundling, and a redistribution of forestry activities in estuaries to accommodate other values. Conflict adjustments and responses have in the past been largely ad hoc and attempted in a jurisdictional vacuum concerning control of coastal management. A more inclusive strategy is now slowly emerging, which involves the coordinated participation of federal, provinicial, and industrial interests. (Author's abstract)

ENVIRONMENTAL ASPECTS OF CLEARING AND SNAGGING,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.
F. D. Shields, Jr., and N. R. Nunnally.
Journal of Environmental Engineering, Vol. 110, No. 1, p 152-165, February, 1984. 2 Fig, 1 Tab, 55 Ref.

Descriptors: *Clearing, *Snagging, *Environmental effects, Flood control, Vegetation, Hydraulic capacity, Detritus, Stream banks, Riparian vegetation.

Clearing and snagging is the removal of woody vegetation and debris from stream channels and banks to increase hydraulic capacity and prevent hazards to navigation or bridges. Clearing and snagging can reducing the frequency and duration of high frequency flooding in environmental sensitive locations. Hydraulic effects of clearing and snagging may be estimated by manipulating the resistance factor in the uniform flow equation. Riparian vegetation and the organic debris it produces influence stream morphology, water quality, and aquatic and terrestrial ecosystems. Complete clearing and snagging has detrimental effects on these stream characteristics; modified clearing and snagging is less damaging to the environment. Major modifications involve: selective removal and disposal of trees and snags based on size, location, condition, and habitat value; labor intensive construction techniques; access controls; and work scheduling to avoid fish spawning or other environmentally sensitive periods. Considerations for planning and design of a selective clearing and snagging project include selection of trees and snags for removal, disposal or utilization of debris, construction equipment and methods, access routes, revegetation, and protection of existing vegetation. Project success is ensured by an interdisciplinary approach, detailed specification, and tight supervision. (Moore-IVI)

COMPARATIVE STUDY OF THE NUTRIENT-SALTS OF LAKE EDKU (EGYPT) BEFORE AND AFTER THE CONSTRUCTION OF ASSWAN'S HIGH DAM IN 1958 AND 1969,
Baden-Wuerttemberg Landesanstalt fuer Umweltschutz (Germany, F.R.).
M. W. Banoub.
Archiv fur Hydrobiologie, Vol. 99, No. 1, p 106-117, December, 1983. 6 Fig, 2 Tab, 7 Ref.

Descriptors: *Dam construction, *Lakes, *Nutrients, Environmental effects, Lake Edku, Egypt, Aswan Dam, Phosphates, Silicates, Acidity.

Comparing the hydrochemical data of Lake Edku in 1958 with those recently published after the construction of the high dam, expressed several changes. The lagoon water-level variations decreased on amplitude and phase where the maximum shifted from summer to winter. Monthly chloride-average of the lagoon reached its maximum in winter in 1969 instead of summer in 1958 indicating the main invasion period by seawater. Phosphates increased from 0.036 to 0.081 mg P/liter between 1958 and 1969. At the same time the P-utilization in the lagoon decreased from 70 to 30%. Silicates decreased from 4.5 to 1.4 mg Si/liter on the average after cessation of the Nile floods. Indications suggesting change in the lagoons macrophytic and hydrophytic production are discussed in relation to the observed changes in water nutrients, pH, alkalinity and the water residence-time. A review of past productivity estimates is discussed in an effort to assess the primary productivity in the lagoon in relation to its past history and its fishery potential. (Baker-IVI)

SPECTRAL MEASUREMENTS OF SURFACE SUSPENDED MATTER IN AN OXBOW LAKE IN THE LOWER MISSISSIPPI VALLEY,
Science and Education Administration, Beltsville, MD.
J. C. Ritchie, F. R. Schiebe, and C. M. Cooper.
Journal of Freshwater Ecology, Vol. 2, No. 2, p 175-181, July, 1983. 6 Fig, 3 Ref.

Descriptors: *Spectral analysis, *Oxbow lakes, *Suspended sediments, Lake Chicot, Arkansas, Surface water, Remote sensing.

Lake Chicot is an oxbow lake located adjacent to the west bank levee of the Mississippi River in Chicot County, Arkansas. Spectral reflectance was successfully used in a study of the lake designed to estimate the concentration of suspended solid in the surface water. Wavelengths between 700 and 900 nm gave the best estimate of the concentration of suspended solids. It should be possible to estimate the concentration of suspended solids in the surface water of Lake Chicot using remote sensing technology. Thus Landsat images, aerial photography, or sensors mounted directly over the water surface and transmitting data could give a reservoir manager valuable data about suspended solids concentration that would be useful in making decisions on the management of water inflow to a lake or reservoir to control water quality. (Baker-IVI)

MEASURING THE MARKET FOR WATER INSTRUMENTS,
R. A. Young.
Pollution Engineering, Vol. 15, No. 8, p 30-33, August, 1983. 3 Fig, 5 Tab.

Descriptors: *Measuring instruments, *Monitoring, Water quality control, Wastewater disposal, Wastewater treatment facilities, Water treatment.

A survey was conducted to determine buying patterns related to water quality instrumentation. To get the most out of a pollution control system, it needs process control instrumentation to ensure that it is running at design standards. Such parameters as temperature, flow, level, humidity, pH, and others should be continuously monitored when applicable. One important development in the field has been the recent establishment of an independent testing program. Of greatest concern at the moment in the industry is the control of hazardous and toxic waste materials. (Baker-IVI)

Descriptors: *Measuring instruments, *Water potentials, Hygrometry, Dewpoint, Calibration, Mathematical equations, Model studies.

Thermocouple hygrometers are considered by some workers as the standard for water potential measurements under temperature controlled conditions, but this confidence does not extend to field conditions. A model for calculating some errors in the measurement of water potential for individual thermocouple hygrometers used in the dewpoint or psychrometric mode is based on calculation of the relative standard error in measured thermocouple psychrometric water potential as a function of temperature. The errors were shown to arise from the variability in the determination of the slope (S) and intercept (I) of the psychrometer block temperature (T) verses 1/kT curve, the error in voltage measurement (which includes zero offset and electronic noise errors) and error in temperature measurement. Assuming a zero offset of 0.5 microV and an error in temperature 0.25 degrees C and a measured water potential of -1250 kPa, the total error ranged betwen 15.6 and 5.5% (at 0 and 45 degrees C, respectively) for the worst psychrometer, and between 5.9 and 2.2% for the best. A similar statisical analysis showed that the magnitude of the error in dewpont water potentail was critically dependent on the dewpoint cooling coefficient. It is recommended that all parameters required for the application of the model be known a priori, so that the error value may be determined routinely. (Baker-IVI).

EVALUATING THE SAFETY AND SEISMIC STABILITY OF EMBANKMENT RESERVOIRS,
Converse Consultants, Inc., Seattle, WA.
D. E. Ryden.
Journal of the American Water Works Association, Vol. 76, No. 1, p 35-39, January, 1984. 3 Fig, 1 Tab, 1 Ref.

Descriptors: *Reservoirs, *Safety, Earthquakes, Seattle, Washington, Earth dams, Embankments, Seismic properties, Stability analysis.

Open storage reservoirs formed by earthen embankments may be classified as facilities with a high seismic hazard potential, especially if the surrounding areas have been heavily developed. A geotechnical evaluation of 12 open embankment reservoirs was undertaken in Seattle, Washington, to determine the safety and seismic stability of the facilities in the event of earthquakes. Most of the reservoirs were constructed from 1901 through 1931 with the oldest being Volunteer Reservoir and the newest being Lake Forest Reservoir (1962). They were typically formed by using a natural topographic swale or slope, escavating into the upper soil levels, and reusing the excavated material to construct an earth embankment 4.5 to 9.1 m high at the lower end of the natural grade. It was recommended that grass be kept trimmed and the brush thinned to permit observation of potential problems such as seepage or slumping. Rodent burrows were noted and it was felt they should be eliminated as their burrow systems could weaken the embankments. Outlet controls should be provided inside the reservoir as well as at the outboard toe of the embankment. Underdrain outlets should be metered to provide a more accurate indication of the quantity of loss through the underdrain systems. A regular periodic inspection program is to be continued. (Baker-IVI)

KEEPING OLD RESERVOIRS ACTIVE,
Portland Bureau of Water Works, OR.
F. Whitfield.
Journal American Water Works Association, Vol. 76, No. 1, p 40-43, January, 1984. 3 Fig.

Descriptors: *Reservoirs, *Maintenance, Portland, Oregon, Open reservoirs, Water storage, Vandalism, Cleaning.

Experience in Portland, Oregon with old open storage reservoirs as well as a variety of covered storage facilities has evolved into a routine cleaning, maintenance, and protective program. Storage of chlorinated water in the open reservoirs in Portland's system requires periodic cleaning to prevent water quality deterioration, and protection of these reservoirs from the public is also important. The Portland Water Board has significantly extended the useful life of the aging facilities with these procedures. These open reservoirs are located in parklike settings. Most are accessible to the public and are about 80 years old. It is the practice in Portland to clean open reservoirs every six months in the spring and fall. Use of hidden cameras guards against vandalism. (Baker-IVI)

RBC BROAD-CRESTED WEIRS FOR CIRCULAR SEWERS AND PIPES,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
A. J. Clemmens, M. G. Bos, and J. A. Replogle.
Journal of Hydrology, Vol. 68, p 349-368, 1984. 8 Fig, 2 Tab, 23 Ref.

Descriptors: *Weirs, Pipes, Sewer systems, Flow, Design criteria.

Existing experience with and theory of long-throated flumes has led to the adaptation of the

RBC Broad-crested weir to flow in circular pipes flowing partly full. The ideal flow equations were solved and the resulting stage-discharge relationship is listed. A mathematical model of flow over broad-crested weirs was used to determine the stage-discharge relationship for actual flow. The results were fit to an empirical equation in non-dimensional form for a wide range of sill heights and pipe sizes. Maximum capacity and head loss requirements for any given weir size are given. Maximum calibration errors result from several sources including: basic calibration, effects of friction not accounted for by Froude modeling, effects of empirical curve fit, and errors in zero setting and depth detection. An example is given which shows how to design these weirs to minimize the effects of the weir on flow conditions in the channel. In many situations, these weirs can be designed to pass a majority of the sediment which moves through the channel. These weris are simple and inexpensive to construct and should be easily adapted to current measurement needs in circular open channels. (Baker-IVI)

THE EFFECTS OF CURVATURE IN SUPERCRITICAL SIDE WEIR FLOW,
Sheffield City Polytechnic (England). Dept. of Civil Engineering.
D. J. Balmforth, and E. J. Sarginson.
Journal of Hydraulic Research, Vol. 21, No. 5, p 333-343, 1983. 6 Fig, 1 Tab, 9 Ref.

Descriptors: *Curvature, *Supercritical flow, *Weirs, Mathematical models, Side weirs, Water depth, Flow discharge, Channel slope, Critical depth.

A method for analyzing supercritical flow in a channel fitted with a side weir has been developed and tested against experimental data. Results of the experimental program have established the conditions under which supercritical flow occurs along a side weir, and showed that in cases where the flow upstream of the weir is subcritical the drawdown to supercritical flow produces sufficient curvature of the streamlines to affect the vertical pressure distribution. Modification of the differential equation to allow for curvature effects has significantly improved the accuracy of computation of depths and discharges. The depth at the upstream end of the weir is shown to be a function of the upstream critical depth, the weir crest height and the slope of the channel, and the rate of change of surface curvature along the upstream portion of the weir is found to depend on the upstream critical depth. Apart from these relationships little use is made of empirical formulae in analysis, so that the method may be applied to any side weir where supercritical low occurs.

DIFFUSION MODEL FOR DEGRADING CHANNELS,
Ahmadu Bello Univ., Zaria (Nigeria). Dept. of Water Resources and Environmental Engineering.
M. A. Gill.
Journal of Hydraulic Research, Vol. 21, No. 5, p 369-378, 1983. 5 Fig, 8 Ref.

Descriptors: *Channel degradation, *Diffusion, *Mathematical models, Fourier series, Error function, Hydraulic models, Dam effects, Sediments, Channel beds.

Degradation problems below dams and in a channel whose downstream end is suddenly lowered are formulated for rectangular channels of finite length. Two specific cases are considered: degradation of channel beds due to sudden reduction of sediment supply at an upstream location with flow conditions otherwise remaining unaltered in its original steady conditions; and degradation of channel beds induced by abrupt lowering of bed level at the downstream end. The first of these situations frequently occurs downstream of dams. The proposed analytical solutions cover the complete range of transient phase terminating in the final steady flow regime. Two types of solutions are obtained. The Fourier series solutions is best suited for computations at large values of time and the error function solution at small values of time. (Moore-IVI)

FLOOD ROUTING THROUGH A FLAT, COMPLEX FLOODPLAIN USING A ONE-DIMENSIONAL UNSTEADY FLOW COMPUTER PROGRAM,
Hydrologic Engineering Center, Davis, CA.
J. C. Peters.
Water Resources Bulletin, Vol. 19, No. 6, p 913-920, December, 1983. 9 Fig, 4 Ref.

Descriptors: *Flood routing, *Floodplains, *Unsteady flow, *Computer models, Flood data, Hydrographs, Flood hydrographs, Model studies, Simulation, Flood waves, Passaic River, New Jersey.

The routing of flood waves through the Central Basin of the Passaic River in New Jersey is complex because of flat gradients and flow reversals. The one-dimensional unsteady flow program DWOPER simulates flood wave movement through the Basin. A historical event was used for calibration, and two synthetic events were simulated. Boundary conditions consisted of discharge hydrographs at inflow points to the study area, local flow hydrographs at interior points, and a stage discharge relation for flow over the crest of a diversion dam at the basin outlet. Manning's values were adjusted based on stage and discharge data for the historical event. Verification data were not available for events comparable in magnitude to the synthetic events. Included are techniques for characterizing the flow system, model calibration, techniques for representing a tunnel diversion, and simulation results. (Murphy-IVI)

EXTREMAL HYPOTHESES FOR RIVER REGIME: AN ILLUSION OF PROGRESS,
G. A. Griffiths.
Water Resources Research, Vol. 20, No. 1, p 113-118, January, 1984. 1 Fig, 34 Ref.

Descriptors: *Channel stability, *Alluvial channels, *Mathematical equations, Sediment transport, River regimes, Flow resistance, Sediment discharge.

The extremal hypotheses of minimum stream power, minimum unit stream power, minimum energy dissipation rate, and maximum sediment transport rate, when combined with conventional sediment transport and flow resistance equations, lead to conclusions incompatible with observations. For wide, straight, unconstrained alluvial reaches in equilibrium, these conclusions include that the Einstein sediment discharge and Shields entrainment function are nearly constant, the magnitude of the particular constants depending only on the hypothesis and equations used, whereas data from flumes and natural rivers show that both expressions are highly variable in stable channels. Constancy of the Einstein and Shields expressions provides, in fact, a sufficient but unnecessary condition for channel stability. In the maximum friction factor hypothesis there is no maximum for friction factor when channel width, depth, and slope are dependent variables. Variational principles may one day supply a solution to the problem of alluvial channel stability, but current formulations of the mentioned hypotheses require redefinition. (Author's abstract)

SENSITIVITY OF OUTFLOW PEAKS AND FLOOD STAGES TO THE SELECTION OF DAM BREACH PARAMETERS AND SIMULATION MODELS,
Illinois State Water Survey Div., Champaign.
K. P. Singh, and A. Snorrason.
Journal of Hydrology, Vol. 68, p 295-310, 1984. 5 Fig, 5 Tab, 9 Ref.

Descriptors: *Dam failure, *Design criteria, *Flood control, Floods, Dams, Earth dams, Model studies, Channels, Dam construction.

A detailed study of historical earthdam failures due to overtopping was reviewed to identify important breach parameters. Various combinations of breach parameters (failure time, depth of overtopping, and breach size) were used for breach simulations in both the US Army Corps of Engineers Hydrologic Engineering Center model and the National Weather Service model. In general, the flood stage profiles predicted by the NWS were smoother and more reasonable than those pedicted by the HEC. For channels with relatively steep slopes, the methods compared fairly well, whereas for the channels with mild slope, the HEC model often predicted oscillating, erratic flood stages, mainly due to inability to route flood waves satisfactorily in non-prismatic channels. The breach outflow peaks are affected significantly by the breach size but less so by the depth of overtopping. The ratio of outflow peak to inflow peak and the effect of failure time on outflow decrease as the drainage area above the dam and impounded storage increase. Flood stage profiles predicted with cross-sections taken from 7.5 foot maps compared favorably with those predicted using surveyed cross-sections. For the range of breach parameters studied, the range of outflow peaks and flood stages downstream from the dam can be determined for regulatory and disaster prevention measures. (Baker-IVI)

EROSIONAL UNLOADING AND FLUID PRESSURES IN HYDRAULICALLY 'TIGHT' ROCKS,
Geological Survey, Reston, VA.
C. E. Neuzil, and D. W. Pollock.
Journal of Geology, Vol. 91, No. 2, p 179-193, 1983. 7 Fig, 35 Ref.

Descriptors: *Erosion, *Fluid pressures, *Rock properties, Rock mechanics, Hydraulic permeability, Hydraulic friction, Pore pressure, Mathematical analysis, Hydrodynamics.

When rocks deform in response to changes in stress, the small variations in pore volume that occur affect the pore fluid pressure. The changes in fluid pressure can be significant if the rate of change of stress is large relative to the rate at which pressure perturbations are dissipated by flow. It has been proposed previously that the gradually increasing loads on sediments undergoing burial can cause excess fluid pressures. We hypothesize that the opposite effect, depression of pore pressure resulting from rebound during erosional unloading, also may occur in certain geologic settings. Simple theoretical treatment of the problem indicates that rocks with small hydraulic diffusivity, such as some shales, could experience significant pore pressure decreases when unloaded by moderate rates of erosion. The analysis further indicates that decreases sufficient to produce nega-

tive pressures can occur. No theoretical bar to this condition exists, and it has been achieved in the laboratory. However, in subsurface environments, it is perhaps more likely that degassing of the pore fluid and resulting increase of gas volume, or desaturation, would occur. Thus it appears that a mechanism exists for generating significant underpressuring and unsaturated conditions below the water table in thick sequences of poorly permeable rock. The analysis also shows that in formations with depressed fluid pressures the groundwater flow is inward from the permeable boundaries for long periods of time. These results may be of importance if toxic materials are to be isolated in 'tight' rocks. (Author's abstract)

A STOCHASTIC MODEL OF A FRACTURED ROCK CONDITIONED BY MEASURED INFORMATION,
Royal Inst. of Tech., Stockholm (Sweden). Dept. of Water Resources Engineering.
J. Andersson, A. M. Shapiro, and J. Bear.
Water Resources Research, Vol. 20, No. 1, p 79-88, January, 1984. 8 Fig, 3 Tab, 20 Ref, 1 Append.

Descriptors: *Geologic fractures, *Stochastic process, *Model studies, *Rock properties, Cores, Groundwater movement, Statistical models.

A method for the modeling of a fractured rock is developed which takes into account the uncertainty in the fracture network geometry as well as actually measured information, such as that obtained from cores. Based on certain simplifying assumptions, of which the most important are planar and independent fractures, a stochastic a priori model is formulated. The real fracture network is assumed to be a realization of this a priori model. Since measurements are performed on the real network, two different kinds of information are made available. The first kind is of deterministic nature and expresses the actual location of intercepted fractures; by inference the other part is probabilistic, given as the probability of observing a fracture intersecting the model region. This observation probability is shown to depend on the a priori model, on the geometry of the region and on the measurements only. A conditional model is formulated where each realization consists of the actually observed fractures and an additional number of stochastically generated fractures obtained by employing the probabilistic information. The number of stochastically generated fractures is a stochastic variable, the distribution of which depends on the number of fractures observed and the observation probability. Even if the rock is penetrated with only a few cores, it is possible to quantify the statistics of properties, such as the total leakage into a tunnel or the concentration of pollutants close to a waste repository. By increasing the number of cores, the uncertainty in these values is reduced. The amount of uncertainty reduction can be quantified by applying the model of the investigated domain taking into account the information from the additional measurements. As a demonstration, the proposed model is applied to a simple problem of steady state two-dimensional flow in a vertical plane. It appears that the technique presented may serve as a powerful tool for quantifying uncertainties in flow problems and in providing guidance on how to acquire additional information of the fractured network in a given domain of fractured rock. INFLUENCE OF DEGREE OF STREAM TURBULENCE ON THE MAGNITUDE OF THE CRITICAL CURRENT VELOCITY FOR FISH,
Akademiya Nauk SSSR, Moscow. Inst. of Evolutionary Morphology and Animal Ecology.
D. S. Pavlov, M. A. Skorobogatov, and L. G. Shtaf.
Doklady Biological Sciences, Vol. 267, No. 1-6, p 560-562, November-December, 1982. 2 Fig, 5 Ref. Translated from Doklady Akademii Nauk SSSR, Vol. 267, No. 4, p 1019-1021, December, 1982.

Descriptors: *Fish behavior, *Turbulence, Streams, Fish, Fisheries, Fish management.

One of the most important characteristics of a stream is the degree of its turbulence. In fish motion the critical current velocity equals the minimum current velocity that exhausts a fish. In order to increase the range of change in the turbulence intensity in the stream, a system of races was created above the upper net with the help of submerged hydraulic spring, acting as a generato of elevated turbulence. Young roach were used i the study. A stream with a higher degree of turbu lence possesses a greater kinetic energy for fis Therefore, the energy expenditures of fish will b higher in such currents, leading to a decline in th critical velocity. The findings should be taken int account in the control of fish behavior. An i crease in the degree of turbulence in active fishin equipment, such as a trawler, will promote th most rapid exhaustion of the fish and an increase the catch. At the same time an increased strea turbulence in the fish tanks of fish-passing struc tures is undesirable as it will result in the loss o fish to the current. (Baker-IVI)

W84-03373 5E

AQUATIC PLANTS
Potential Phytotoxicity of Diquat Accumulated by Aquatic Plants and Sediments,
W84-02990 5C

AQUATIC POLLUTANTS
Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium,
W84-03114 5C

AQUATIC WEEDS
Growth of Salvinia molesta as Affected by Water Temperature and Nutrition; II. Effects of Phosphorus Level,
W84-03192 5C

A Study on the Growth of Salvinia molesta Mitchell in Relation to Light and Temperature,
W84-03194 5C

AQUIFER CHARACTERISTICS
The Investigation of Aquifer Parameters Using Multiple Piezometers,
W84-03075 2F

AQUIFER TESTING
Determination of Horizontal Aquifer Anisotropy with Three Wells,
W84-03080 2F

AQUIFERS
Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

A Column Technique for Determining Sorption of Organic Solutes on the Lithological Structure of Aquifers,
W84-03129 5A

The Variability of Recharge of the English Chalk Aquifer,
W84-03439 2F

Delayed Yield. An Exact Quasi-Three Dimensional Model for Free-Aquifers,
W84-03460 2F

ARTHURS LAKE
Macrobenthic Fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania,
W84-03125 2H

Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

ARTIFICIAL RECHARGE
Microcomputer Model of Artificial Recharge Using Glover's Solution,
W84-03081 4B

Ground-Water Mounding Beneath a Large Leaching Bed,
W84-03083 4B

Engineering Economic Analyses of Artificial Recharge in the Columbia Basin Project, Washington,
W84-03402 4B

ASELLUS
Oxygen Consumption and Survival of Asellus aquaticus L. (Crustacea) in Vistula River Section Highly Polluted by Municipal Sewage,
W84-03155 5C

ASHES
Studies on the Leaching and Weathering Processes of Coal Ashes,
W84-03377 5E

ASSESSMENT
Utilization and Assessment of Operational Weather Modification Programs for Augmenting Precipitation,
W84-03449 3B

AUGHER LOUGH
The Physical Limnology of Augher Lough (Northern Ireland),
W84-03294 2H

AUSTRALIA
Crop-Climate Modeling Using Spatial Patterns of Yield and Climate. Part 1: Background and an Example from Australia,
W84-03302 2I

Hydroelectric Development and Wilderness Conflict in South-West Tasmania,
W84-03324 6G

BACKWATERS
Allochthonous Drift from Backwaters to the Main Channel of the Mississippi River,
W84-03323 2E

BACTERIA
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

Studies on Bacteriological Quality of Nainital Lake Water in Different Seasons,
W84-02989 5E

The Impact of Zooplankton Feeding on the Epilimnetic Bacteria of a Eutrophic Lake,
W84-03290 2H

The Importance of Attachment to Particles for Planktonic Bacteria,
W84-03495 2H

Degradability of Dissolved Organic Lake Water Compounds in Cultures of Natural Bacteria Communities,
W84-03503 2H

BACTERIAL ANALYSIS
Separation of Bacteria from a Methanogenic Wastewater Population by Utilizing a Self-Generating Percoll Gradient,
W84-03164 5D

BACTERIOPLANKTON
Biomass and Production of Phyto- and Bacterioplankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

The Importance of Attachment to Particles for Planktonic Bacteria,
W84-03495 2H

BAGHDAD
Quality Changes in Baghdad Canals and Irrigation,
W84-03148 5E

BAKHIRA LAKE
A Study on the Macro-Zoobenthos and the Physico-chemical Characteristics of the Bottom of Bakhira Lake, Uttar Pradesh, India,
W84-02959 2H

BANK STABILIZATION
Evaluating Riprapping and Other Streambank Stabilization Techniques,
W84-03220 4D

BARLEY
Genotypic Variation for Glycinebetaine Accumulation by Cultivated and Wild Barley in Relation to Water Stress,
W84-03278 2I

Leaching Requirement for Salinity Control III. Barley, Cowpea, and Celery,
W84-03431 3C

Water Use by Alfalfa, Maize, and Barley as Influenced by Available Soil Water,
W84-03444 2I

BASELINE STUDIES
Preliminary Study of the Diversion of 283 cu m/s (10,000 cfs) from Lake Superior to the Missouri River Basin,
W84-03356 4B

BASINS
Comparison of Basin Performance Modeling Techniques,
W84-03088 5A

BASS
A Stochastic Age-Structured Population Model of Striped Bass (Morone saxatilis) in the Potomac River,
W84-03023 2H

BAYS
Transient Hydrodynamic and Salinity Simulations in the Chesapeake Bay Network,
W84-03037 2L

Plankton Productivity and Biomass in a Tributary of the Upper Chesapeake Bay. I. Importance of Size-Fractionated Phytoplankton Productivity, Biomass and Species Composition in Carbon Export,
W84-03200 2L

BEANS
Response of Dry Beans to Daily Deficit Sprinkler Irrigation,
W84-03262 3F

BECKMAN MICROTOX ASSAY SYSTEM
The Microtox* as an Alternative Assay in the Acute Toxicity Assessment of Water Pollutants,
W84-03120 5C

BED LOAD
Bed Load Formulae for Alluvial Channels,
W84-03464 2J

BELGIUM
The Algal Communities of the Upper Belgian Meuse and the Water Quality: A Synthesis at Fall 1981 (Les Communautes Algales de la Haute Meuse Belge et la Qualite de ses Eauz: Un Bilan a l'Automene 1981),
W84-03127 2H

The Nature Reserve s'Gravendel (Retie, Belgium); I. Phytosociological Description in Relation to Moisture and Soil Conditions (Het Natuurgebied 's-Gravendel (Retie, Belgie); I. Fitosociologische Beschrijving in Relatie tot Vochtigheid en Bodem),
W84-03128 2L

BENTHIC ENVIRONMENT
The Distribution of Desmognathine Larvae (Amphibia: Plethodontidae) in Coal Surface Mine Impacted Streams of the Cumberland Plateau, USA,
W84-02961 2H

An Index of Community Structure Sensitive to Water Pollution,
W84-02966 5C

Allochthonous Drift from Backwaters to the Main Channel of the Mississippi River,
W84-03323 2E

BENTHIC FAUNA
A Study on the Macro-Zoobenthos and the Physico-chemical Characteristics of the Bottom of Bakhira Lake, Uttar Pradesh, India,
W84-02959 2H

Benthic Macroinvertebrates and Water Quality Assessment: Some Toxicological Considerations,
W84-03118 5C

Macrobenthic Fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania,
W84-03125 2H

Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

BENTHOS
Environmental Gradients and Benthic Macroinvertebrate Distributions in a Shallow North Carolina Estuary,
W84-02977 2L

Geothermal Effects on Stream Benthos: Separate Influences of Thermal and Chemical Components on Periphyton and Macroinvertebrates,
W84-03019 5C

BETHLAHMY'S TWO-AXIS METHOD
Basin Precipitation Estimates by Bethlahmy's Two-Axis Method,
W84-03341 2B

BHAGALPUR
A Quantitative Study of Phytoplankton of the River Ganges at Bhagalpur, India,
W84-03151 2H

BIOACCUMULATION
The Distribution and Accumulation of Aluminum in Rainbow Trout Following a Whole-Lake Alum Treatment,
W84-02963 5B

Contaminant Accumulation and Physiological Response in Rainbow Trout (Salmo gairdneri) Reared on Naturally Contaminated Diets,
W84-03018 5C

Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

Effects of Accumulated Dietary Kepone on Spot (Leiostomus xanthurus),
W84-03115 5C

BIOASSAY
The Microtox* as an Alternative Assay in the Acute Toxicity Assessment of Water Pollutants,
W84-03120 5C

Bioassays with Stigeoclonium Kutz. (Chlorophyceae) to Identify Nitrogen and Phosphorus Limitations,
W84-03193 5A

A Model Relating the Results of Low pH Bioassay Experiments to the Fishery Status of Norwegian Lakes,
W84-03298 5C

BIOAVAILABILITY
Bonding Forms of Heavy Metals in Sediments and Sludges: Sorption/Mobilization, Chemical Extraction and Bioavailability (Bindungsformen von Schwermetallen in Sedimenten und Schlammen: Sorption/Mobilisierung, chemische Extraktion und Bioverfugbarkeit),
W84-03188 5B

BIODEGRADATION
Degradability of Dissolved Organic Lake Water Compounds in Cultures of Natural Bacterial Communities,
W84-03503 2H

BIOINDICATORS
Charr as Indicators of Pollution,
W84-03198 5C

BIOLOGICAL PROPERTIES
Predicting Algal Stimulatory Properties of Wastewater,
W84-03089 5C

Properties of Acid Brown Water Streams in South Sweden,
W84-03502 5C

BIOLOGICAL WASTEWATER TREATMENT
Occurrence of Low- and High-Chlorinated Phenols in Municipal Sewage Before and After Passing Through Biological Treatment Plants,
W84-03159 5D

BIOMASS
The Relationship Between Nutrient Availability, Shoot Biomass and Species Richness in Grassland and Wetland Communities,
W84-02974 2I

The Ecology of Lake Nakuru (Kenya); IV. Biomass and Distribution of Consumer Organisms,
W84-03149 2H

Biomass and Production of Phyto- and Bacterio-Plankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

BIOTIC RECOVERY
The Recovery of the Biotic Community in a Lotic Freshwater Habitat after Extensive Destruction by Chlorine,
W84-02951 5C

BLEAK
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

BOLSTADFJORD
The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W. Norway,
W84-03135 2K

BOTTOM FAUNA
Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

BOTTOM SAMPLING
A Study on the Macro-Zoobenthos and the Physico-chemical Characteristics of the Bottom of Bakhira Lake, Uttar Pradesh, India,
W84-02959 2H

BOTTOM SEDIMENTS
Thermal Conditions of Bottom Sediments in Five Shallow Lakes of Masurian Lakeland,
W84-03134 2H

Endogenic Flux of Manganese to the Bottom of Lake Constance,
W84-03493 5B

BOUNDARIES
Baseline Delimitations and Maritime Boundaries,
W84-03237 6E

BOUNDARY LAYERS
On the Application of the Boundary Layer Approximation for the Simulation of Density Stratified Flows in Aquifers,
W84-03463 2F

BOUSSINESQ EQUATION
A Simple Analytical Solution for the Boussinesq One-Dimensional Groundwater Flow Equation,
W84-03409 2F

BRAZIL
The Altamira Hydro Complex in the Amazon Region,
W84-02995 6B

BRAZOS RIVER
Forage Fish Assemblages in the Brazos River Upstream and Downstream from Possum Kingdom Reservoir, Texas,
W84-02964 2H

BREAM
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

BRITISH COLUMBIA
Periphyton Biomass and Species Composition in a Coastal Rainforest Stream in British Columbia: Effects of Environmental Changes Caused by Logging,
W84-03016 5C

Effects of Clearcutting and Slash Burning on Streamwater Chemistry and Watershed Nutrient Budgets in Southwestern British Columbia,
W84-03410 5B

Marine Log Transportation and Handling Systems in British Columbia: Impacts on Coastal Management,
W84-03424 6G

BROCCOLI
Fertilizer Application and Irrigation Management of Broccoli Production and Fertilizer Use Efficiency,
W84-03252 3F

BYRON-BERGEM SWAMP
Gradient Analysis of the Vegetation of the Byron-Bergen Swamp, a Rich Fen in Western New York,
W84-02973 2L

CADMIUM
Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium,
W84-03114 5C

The Effects of Coal Combustion and Acidification on the Cadmium Exposure of the Swedish Population,
W84-03389 5B

Cadmium Adsorption by Aerobic Lake Sediments,
W84-03477 5B

CALCAREOUS SOILS
An Attempt to Pre-Determine Low Water Flows in Streams Losing Water in Calcareous Regions: Example of the Tille River Between Til-Chatel and Spoy (21) (Essai de Predetermination des Debits d'Etiage Sur les Cours d'Eau Presentant des Pertes en Region Calcaire. L'Exemple de la Tille Entre Til-Chatel et Spoy (21)),
W84-03362 2E

CALCITE PRECIPITATION
Calcite Precipitation as a Natural Control Mechanism of Eutrophication,
W84-03496 2H

CALIBRATIONS
Calibration of NPS Model Loading Factors,
W84-03093 5B

CANALS
Quality Changes in Baghdad Canals and Irrigation,
W84-03148 5B

CANOPY
Direct Evaporation from Soil Under a Row Crop Canopy,
W84-03204 2D

Evaporation from the Irrigation Water, Foliage and Panicles of Paddy Rice in North-East Sri Lanka,
W84-03206 2D

Simulating the Effects of Weather Variables and Soil Water Potential on a Corn Canopy Temperature,
W84-03210 3F

Evapotranspiration and Yield Estimation of Spring Wheat From Canopy Temperature,
W84-03264 2D

Relationships Between Leaf Water Potential, Canopy Temperature, and Evapotranspiration in Irrigated and Nonirrigated Alfalfa,
W84-03270 2D

Soybean Water Status and Canopy Microclimate Relationships at Four Row Spacings,
W84-03273 2I

Alfalfa Response to Soil Water Deficits. II. Plant Water Potential, Leaf Conductance, and Canopy Temperature Relationships,
W84-03282 2D

CANOPY TEMPERATURES
Leaf and Canopy Temperatures of Pearl Millet Genotypes Under Irrigated and Nonirrigated Conditions,
W84-03251 3F

CAPE COD
The Reproductive Cycle of the Bay Scallop, Argopecten irradians irradians (Lamarck), in a Small Coastal Embayment on Cape Cod, Massachusetts,
W84-03039 2L

CAPILLARY BARRIER
Use of 'The Capillary Barrier' as a Shield Against Groundwater Pollution from Fly-Ash Deposits,
W84-03378 5E

CARBON
Uptake, Translocation and Release of Carbon by Submersed Macrophytes from Running Water Habitats (Aufnahme, Transport und Abgabe von Kohlenstoff durch Submerse Makrophyten von Fliesswasserstandorten,
W84-03175 2H

CARBON DIOXIDE
Carbon Dioxide Emission and Carbon Accumulation in Coastal Wetlands,
W84-03136 5B

Seasonal Fluctuations in the Carbon Dioxide Partial Pressure in a Cave Atmosphere,
W84-03422 2A

CARBONATES
Carbonate Mineralogy of Lake Sediments and Surrounding Soils. 2. The Qu'Apelle Lakes,
W84-03224 2H

CASCADES
Stochastic Nature of Outputs from Conceptual Reservoir Model Cascades,
W84-03342 2A

CATCHMENT AREAS
Acid Rain, Catchment Characteristics and Fishery Status,
W84-03385 5C

CATIONS
Relationships Between Chloride and Major Cations in Precipitation and Streamwaters in the Windermere Catchment (English Lake District),
W84-03297 5B

CATTLE
Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream,
W84-03057 5B

CAVES
Seasonal Fluctuations in the Carbon Dioxide Partial Pressure in a Cave Atmosphere,
W84-03422 2A

CELERY
Leaching Requirement for Salinity Control III. Barley, Cowpea, and Celery,
W84-03431 3C

CENTRAL ELECTRIC GENERATING BOARD
The Handling and Disposal of Coal Ash in the CEGB in Relation to the Aqueous Environment,
W84-03373 5E

CHANNEL DEGRADATION
Diffusion Model for Degrading Channels,
W84-03166 8B

CHANNEL STABILITY
Extremal Hypotheses for River Regime: An Illusion of Progress,
W84-03417 8B

CHARR
Charr as Indicators of Pollution,
W84-03198 5C

CHEMICAL ANALYSIS
Chemistry of Dissolved and Particulate Material in the Estuary of the Rimouski River (Contribution a L'Etude Chimique du Materiel Dissous et Particulaire de L'Estuaire de la Riviere Rimouski),
W84-03108 2L

CHEMICAL BINDING
Material Balance of Aquatic Ecosystems and Chemical Binding (Vom Stoffhaushalt aquatischer Okosysteme zur Frage nach der chemischen Bindung),
W84-03186 2K

On the Coordination Between Metals and Aquatic Humic Material (Zur koordinativen

Bindung von Metallionen an Gewasserhuminstoffe),
W84-03187 5B

Bonding Forms of Heavy Metals in Sediments and Sludges: Sorption/Mobilization, Chemical Extraction and Bioavailability (Bindungsformen von Schwermetallen in Sedimenten und Schlammen: Sorption/Mobilisierung, chemische Extraktion und Bioverfugbarkeit),
W84-03188 5B

CHEMICAL COMPOSITION
A Comparative Study of the Ionic Composition of Rainwater and Atmospheric Aerosols: Implications for the Mechanism of Acidification of Rainwater,
W84-03287 2K

Chemical Composition of Water-Bodies in the English Lake District: Relationships Between Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

CHEMICAL PROPERTIES
Dynamics of Physical and Chemical Parameters in Okefenokee Swamp,
W84-02968 2L

Properties of Acid Brown Water Streams in South Sweden,
W84-03502 5C

CHEMICAL REACTIONS
Chemical Pathways from Stack Emissions to Surface Water,
W84-03383 5B

CHEMICAL SPECIATION
Investigations on Heavy Metal Speciation in Natural Waters by Voltammetric Procedures,
W84-03185 5B

CHINA
Crop Water Requirements for Rainfed and Irrigated Grain Corn in China,
W84-03435 2D

CHIRONOMID LARVAE
Production and Ecology of Benthic Chironomid Larvae (Diptera) in Lake Hayes, New Zealand, a Warm-monomictic Eutrophic Lake,
W84-02955 2H

CHIRONOMIDS
Changes in the Chironomid (Diptera: Chironomidae) Fauna of Laurel Creek Reservoir, Waterloo, Ontario,
W84-02965 2H

CHLORIDE
Relationships Between Chloride and Major Cations in Precipitation and Streamwaters in the Windermere Catchment (English Lake District),
W84-03297 5B

Sulphur and Chloride Deposition and Ecosystem Transport in a Strongly Acidified Lake Watershed,
W84-03388 5B

CHLORIDES
Chemical Composition of Water-Bodies in the English Lake District: Relationships Between Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

CHLORINATED PHENOLS
Occurrence of Low- and High-Chlorinated Phenols in Municipal Sewage Before and After Passing Through Biological Treatment Plants,
W84-03159 5D

Direct Determination of Trace Amounts of Chlorophenols in Fresh Water, Waste Water and Sea Water,
W84-03160 5A

CHLORINATION
Chlorination-Filtration for Iron and Manganese Removal,
W84-03142 5F

CHLORINE
The Recovery of the Biotic Community in a Lotic Freshwater Habitat after Extensive Destruction by Chlorine,
W84-02951 5C

CHROMATOGRAPHY
Possibilities and Limitations of Tracing Industrial Effluents in the Sea by Means of Capillary Chromatography,
W84-03158 5A

A High-Speed Liquid Chromatography of Phosphorus in Anoxic Waters Occurring in a Bay Using Solvent Extraction of Molybdoheteropoly Yellow,
W84-03288 5A

CLAMS
Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

CLAY SOIL
Response of Soybean Cultivars to Irrigation of a Clay Soil,
W84-03268 3F

CLEAR-CUTTING
Effects of Clearcutting and Slash Burning on Streamwater Chemistry and Watershed Nutrient Budgets in Southwestern British Columbia,
W84-03410 5B

CLEARING
Environmental Aspects of Clearing and Snagging,
W84-03473 6G

CLIMATE
Short-Term Climate Predictions for Water Management,
W84-03156 4A

Crop Water Requirements for Rainfed and Irrigated Grain Corn in China,
W84-03435 2D

CLIMATES
Crop-Climate Modeling Using Spatial Patterns of Yield and Climate. Part 1: Background and an Example from Australia,
W84-03302 2I

Supercooled Liquid Water and Ice Crystal Distributions Within Sierra Nevada Winter Storms,
W84-03303 2B

CLIMATOLOGY
Climatic Effects on the Recession of the Franz Josef Glacier,
W84-03483 2C

CLOUD SEEDING
Augmentation of Rainfall from Summer Cumulus Clouds,
W84-03448 3B

CLOUDS
Supercooled Liquid Water and Ice Crystal Distributions Within Sierra Nevada Winter Storms,
W84-03303 2B

COAL
Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash,
W84-03374 5B

Studies on the Leaching and Weathering Processes of Coal Ashes,
W84-03377 5E

COAL ASH
The Handling and Disposal of Coal Ash in the CEGB in Relation to the Aqueous Environment,
W84-03373 5E

COAL MINING
Use of Geostatistics to Evaluate Water Quality Changes Due to Coal Mining,
W84-03404 5B

COASTAL MARSHES
Carbon Dioxide Emission and Carbon Accumulation in Coastal Wetlands,
W84-03136 5B

COASTAL STREAMS
Periphyton Biomass and Species Composition in a Coastal Rainforest Stream in British Columbia: Effects of Environmental Changes Caused by Logging,
W84-03016 5C

COASTAL ZONE MANAGEMENT
Marine Log Transportation and Handling Systems in British Columbia: Impacts on Coastal Management,
W84-03424 6G

Assessing Land-Use Regulations in Coastal Wetlands: The Case of the Long Point Area, Lake Erie, Ontario,
W84-03425 6F

COLIFORMS
Studies on Bacteriological Quality of Nainital Lake Water in Different Seasons,
W84-02989 5B

COLORADO
Sporhase v. Nebraska ex rel. Douglas: Does the Dormant Commerce Clause Really Limit the Power of a State to Forbid (1) the Export of Water and (2) the Creation of a Water Right for Use in Another State,
W84-03013 6E

Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream,
W84-03057 5B

COLORADO RIVER
Concentrations of Total Dissolved Solids Preferred or Avoided by Endangered Colorado River Fishes,
W84-03314 5C

COLUMBIA BASIN PROJECT
Engineering Economic Analyses of Artificial Recharge in the Columbia Basin Project, Washington,
W84-03402 4B

COLUMBIA RIVER ESTUARY
Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

COMMUNITY DEVELOPMENT
Community Structure in Some Southern English Streams: The Influence of Physicochemical Factors,
W84-03300 5C

The Colonization of Ball-Clay Ponds by Macroinvertebrates and Macrophytes,
W84-03301 2H

COMPARISON STUDIES
Comparison of Basin Performance Modeling Techniques,
W84-03088 5A

COMPUTER MODELS
Microcomputer Model of Artificial Recharge Using Glover's Solution,
W84-03081 4B

Model of Mississippi River Pool: Mass Transport,
W84-03084 2E

Numerical Models for the Currents Simulation of a Lake (Mathematische Modelle zur Simulation von Zirkulationsstromungen in Einem See),
W84-03171 2H

Flood Routing Through a Flat, Complex Floodplain Using a One-Dimensional Unsteady Flow Computer Program,
W84-03395 8B

COMPUTERS
Low Flow Synthesis by Computer; Part One,
W84-02996 2E

Low Flow Synthesis by Computer; Part Two,
W84-02997 2E

Treatment Plants Enter Computer Immersion Phase,
W84-03099 5D

Computer Schedules Irrigation,
W84-03230 3F

CONCENTRATIONS
Concentrations of Total Dissolved Solids Preferred or Avoided by Endangered Colorado River Fishes,
W84-03314 5C

CONDUCTIVITY
Relationships Between Ground-water Silica, Total Dissolved Solids, and Specific Electrical Conductivity,
W84-03082 5A

CONFINED AQUIFERS
Optimum Management of a Regional Confined Aquifer,
W84-03461 2F

CONFINED GROUNDWATER
Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

CONSERVATION TILLAGE
Water Quality Consequences of Conservation Tillage,
W84-03060 4D

Soil and Nutrient Runoff Losses with In-Row, Chisel-Planted Soybeans,
W84-03062 2J

CONSUMER ORGANISMS
The Ecology of Lake Nakuru (Kenya); V. Production and Consumption of Consumer Organisms,
W84-03150 2H

CONSUMPTION
The Ecology of Lake Nakuru (Kenya); V. Production and Consumption of Consumer Organisms,
W84-03150 2H

CONTACT FILTERS
Chemical Optimization of Tertiary Contact Filters,
W84-03479 5D

CONTAMINATION
Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

CONVECTION
Comments Concerning 'Convection Patterns in a Pond',
W84-02981 2C

Thermohaline Convection in Flowing Groundwater,
W84-03465 2F

Convection in an Aquifer Above a Layer of Heated Impermeable Bedrock,
W84-03480 2F

COOLING WATER
Using Blowdown Water to Irrigate Crops,
W84-03218 3C

Dechlorination of Wastewater and Cooling Water,
W84-03325 5D

COPPER
Material Balance of Aquatic Ecosystems and Chemical Binding (Vom Stoffhaushalt aquatischer Okosysteme zur Frage nach der chemischen Bindung),
W84-03186 2K

COREGONUS
The Coregones of Lake Neuchatel: Fishery Yield; Age and Growth of Individuals Caught by Professional Fishermen (Les coregones du lac de Neuchatel: rendement de la peche; age et croissance des individus captures par les pecheurs professionnels),
W84-03176 5C

CORN
Effect of Folicote Antitranspirant Application on Field Grain Yield of Moisture-Stressed Corn,
W84-03255 3F

Comparative Physiology and Water Relations of Two Corn Hybrids During Water Stress,
W84-03276 2I

Crop Water Requirements for Rainfed and Irrigated Grain Corn in China,
W84-03435 2D

Water Use by Alfalfa, Maize, and Barley as Influenced by Available Soil Water,
W84-03444 2I

CORROSION
Lead in Drinking Water-Investigation of a Corrosive Water Supply,
W84-02983 5F

COST-BENEFIT ANALYSIS
The Third Wave in Water Quality Management,
W84-02980 6E

Controlling Agricultural Soil Loss in Arkansas' North Lake Chicot Watershed: An Analysis of Benefits,
W84-03071 6B

COWPEA
Leaching Requirement for Salinity Control III. Barley, Cowpea, and Celery,
W84-03431 3C

CRITICAL POINT
Critical Point Method for Mixing Zones in Rivers,
W84-03478 5B

CROP YIELD
Irrigation + Dryland Farming + Limited Tillage: A Profitable Combination,
W84-03061 4D

Soil Erosion and Productivity, A Rational Look at a Complex Situation,
W84-03231 2

Crop Yield - Irrigation Relationships in a Gypsiferous-Sodic Soil,
W84-03248 3

Wetting and Maturity Effects on the Yield and Quality of Legume Hay,
W84-03253 2

Effect of Folicote Antitranspirant Application on Field Grain Yield of Moisture-Stressed Corn
W84-03255 3

Evapotranspiration and Yield Estimation of Spring Wheat From Canopy Temperature,
W84-03264 2

Yield and Water Relations of Pearl Millet Genotypes under Irrigated and Nonirrigated Conditions,
W84-03269 2

Yield, Water Relations, Gas Exchange, and Surface Reflectances of Near-Isogenic Wheat Lines Differing in Glaucousness,
W84-03277 2

Alfalfa Response to Soil Water Deficits. Growth, Forage Quality, Yield, Water Use, and Water-Use Efficiency,
W84-03281 2

Crop-Climate Modeling Using Spatial Pattern of Yield and Climate. Part 1: Background and a Example from Australia,
W84-03302 2

Effect of Small Irrigation Amounts on the Yield of Wheat,
W84-03434 3

Wheat Root Growth, Grain Yield and Water Uptake as Influenced by Soil Water Regime and Depth of Nitrogen Placement in a Loamy Sand Soil,
W84-03445 2

CROPS
Seasonal Estimates of Transpiration from Millet Crop Using a Porometer,
W84-03214 2

CROSS-COMPLIANCE
Cross-Compliance to Enforce Soil and Water Conservation,
W84-03053 4

CULTIVATION
Effects of Wastewater Irrigation and Plant and Row Spacing on Soybean Yield and Development,
W84-03271 3

Soybean Water Status and Canopy Microclimate Relationships at Four Row Spacings,
W84-03273

Genotypic Variation for Glycinebetaine Accumulation by Cultivated and Wild Barley in Relation to Water Stress,
W84-03278

CULTURAL MANAGEMENT
Tillage and Cultural Management of Irrigated Potatoes,
W84-03242 2

CUMULUS CLOUDS
Augmentation of Rainfall from Summer Cumulus Clouds,
W84-03448 3

CURVATURE
The Effects of Curvature in Supercritical Side Weir Flow,
W84-03165 8B

CYANOBACTERIA
Toxicity of Cyanobacteria in Dutch Lakes and Reservoirs,
W84-03117 2H

DAKOTA AQUIFER
Geohydrology and Hydrochemistry of the Dakota Aquifer, Central United States,
W84-03394 2F

DAM CONSTRUCTION
The Altamira Hydro Complex in the Amazon Region,
W84-02995 6B

Magat River Multipurpose Project,
W84-02998 6B

Development of Water Resources in Korea,
W84-02999 6B

Comparative Study of the Nutrient-Salts of Lake Edku (Egypt) Before and After the Construction of Asswan's High Dam in 1958 and 1969,
W84-03504 6G

DAM FAILURE
Sensitivity of Outflow Peaks and Flood Stages to the Selection of Dam Breach Parameters and Simulation Models,
W84-03348 8D

DAMS
Hydraulic Characteristics of the Current That Produces Routes for Fish Movement,
W84-03029 8I

Hydrobiological Study of a Harnessed River: The Verdon (Etude Hydrobiologique d'une Riviere Amenagee: le Verdon Les Lacs de Barrage et les Troncons de Cours d'Eau a Debit Regule),
W84-03360 6G

DAPHNIA
Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. V. Reproduction of Daphnia Pulex and Overall Evaluation,
W84-03124 5C

DDT
PCB and DDT Concentrations of Sediments from Swiss Shoreline of Lake Geneva, Switzerland, (Concentrations en PCB et DDT des Sediments Superficiels de la Rive Suissec du Lac Leman),
W84-03173 5B

DECHLORINATION
Dechlorination of Wastewater and Cooling Water,
W84-03325 5D

DECOMPOSING ORGANIC MATTER
Decomposition of Organic Matter in Lake Sediments,
W84-03032 2J

Elevated Concentrations of Humic Substances in a Seasonally Anoxic Hypolimnion: Evidence for Co-Accumulation with Iron,
W84-03488 5B

DELAWARE
Impact of Land Use on Ground-water Quality in Southern Delaware,
W84-03077 5B

DENMARK
Biomass and Production of Phyto- and Bacterio-Plankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

DENSITY GRADIENT SEPARATION
Separation of Bacteria from a Methanogenic Wastewater Population by Utilizing a Self-Generating Percoll Gradient,
W84-03164 5D

DENSITY STRATIFICATION
On the Application of the Boundary Layer Approximation for the Simulation of Density Stratified Flows in Aquifers,
W84-03463 2F

DEPOSITION
Sulphur and Chloride Deposition and Ecosystem Transport in a Strongly Acidified Lake Watershed,
W84-03388 5B

Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry,
W84-03390 5B

DESIGN CRITERIA
Operational Flood Routing for Hydroelectric Plants,
W84-02993 4A

Magat River Multipurpose Project,
W84-02998 6B

Sensitivity of Outflow Peaks and Flood Stages to the Selection of Dam Breach Parameters and Simulation Models,
W84-03348 8D

DESIGN STORMS
Urban Design-Storm Sensitivity and Reliability,
W84-03336 4A

DESMIDS
The Desmids and Physical Characteristics of 100 Lakes in Northeastern Pennsylvania,
W84-02962 2H

DESORPTION
Soil Water Desorption Curves Estimated from Limited Data,
W84-03229 2G

DETERGENTS
Sedimentation of Zeolite Type A in Water and Wastewater,
W84-02978 5F

DEVELOPING COUNTRIES
Soil Conservation Strategies in the Third World,
W84-03068 4D

Providing Water Supplies and Sanitation for the Developing World,
W84-03101 6B

DIATOMS
Pelagic Diatom Populations in Lentic Freshwater Microcosms,
W84-02953 2H

Diatoms in Fountains, Reservoirs and Some Other Humid and Dry Localities in Rome, Italy,
W84-03311 2H

The Geochemical Record of Major Cations and Trace Metals in a Productive Lake; Analysis of Thinly Sliced Sediment Samples Characterised by Diatom Stratigraphy,
W84-03500 2H

DICHLOROBENZENE
Technical Note: Adsorption of p-Dichlorobenzene from Water,
W84-03370 5D

DIEL VARIATIONS
Diel Oxygen Variations and Their Ecological Implications in Amazon Floodplain Lakes,
W84-03498 2H

DIETS
Effects of Accumulated Dietary Kepone on Spot (Leiostomus xanthurus),
W84-03115 5C

DIFFUSION
Diffusion Model for Degrading Channels,
W84-03166 8B

DIFFUSION COEFFICIENT
Diffusivity-Based Flux of Phosphorus in Onondaga Lake,
W84-03097 5B

DIFFUSIVITY
A Transient Method for Measuring Soil Water Diffusivity and Unsaturated Hydraulic Conductivity,
W84-03178 2G

Effect of Mixed Cation Solutions on Hydraulic Soil Properties,
W84-03432 2G

DISAGGREGATION
Disaggregation Procedures for Generating Serially Correlated Flow Vectors,
W84-03412 2E

DISPERSANTS
A Model of the Dispersion of Soluble of Pseudo-Soluble Substances in Waterways. Application to the case of the Seine Upstream of Paris (Modelisation de la Dispersion des Substances Solubles ou Pseudo-Solubles dans un Cours d. Eau. Application au Cas de la Seine a l'Amont de Paris),
W84-03358 5A

DISPOSAL
The Handling and Disposal of Coal Ash in the CEGB in Relation to the Aqueous Environment,
W84-03373 5E

DISSOLVED ORGANIC MATTER
Microbial Heterotrophic Utilization of Dissolved Organic Matter in a Piedmont Stream,
W84-03295 5B

The Seasonal Variation of Organic Constituents in a Eutrophic Lake, Lake Suwa, Japan; Part II. Dissolved Organic Matter,
W84-03499 2H

DISSOLVED OXYGEN
Model of Mississippi River Pool: Dissolved Oxygen,
W84-03085 2H

Use of Dissolved Oxygen Modeling Results in the Management of River Quality,
W84-03430 5G

Diel Oxygen Variations and Their Ecological Implications in Amazon Floodplain Lakes,
W84-03498 2H

DISSOLVED SOLIDS
Relationships Between Ground-water Silica, Total Dissolved Solids, and Specific Electrical Conductivity,
W84-03082 5A

Degradability of Dissolved Organic Lake Water Compounds in Cultures of Natural Bacterial Communities,
W84-03503 2H

DISTRIBUTION
Moisture Stress and N Redistribution in Soybean,
W84-03275 2I

DISTRICT OF COLUMBIA
Lagrangian Meteorology and Measurements of Acidic Precipitation at Washington, D.C.,
W84-03286 5B

DIURNAL DISTRIBUTION
Field Evaluation of a Water Relations Model for Soybean, II. Diurnal Fluctuations,
W84-03246 2I

Influence of Water Stress on the Diurnal Exchange of Mass and Energy Between the Atmosphere and a Soybean Canopy,
W84-03254 2I

DIVERSION
Preliminary Study of the Diversion of 283 cu m/s (10,000 cfs) from Lake Superior to the Missouri River Basin,
W84-03356 4B

DOMESTIC WASTES
Studies on Stabilization Ponds for Domestic Sewage in India,
W84-02957 5D

DRAINAGE
Toward a Unified Reasonable Use Approach to Water Drainage in Washington,
W84-03014 6E

DRAINAGE CHANNELS
The Macroinvertebrate Fauna of the Drainage Channels of the Gwent Levels, South Wales,
W84-03289 5C

DRAINS
A Heuristic Model of Soil Water Regimes in Clay Soils in the Presence of Mole Drainage,
W84-03438 2G

DREISSENA
Ecology of Planktonic Larvae of Dreissena polymorpha (Pall.) in Lakes with Different Degree of Heating,
W84-03152 5C

DRINKING WATER
Lead in Drinking Water-Investigation of a Corrosive Water Supply,
W84-02983 5F

Fluoride in the Ground Water of Northeastern Ohio,
W84-03073 2F

The Occurrence of Aluminum in Drinking Water,
W84-03144 5F

Control of Trihalomethane Precursors in Drinking Water: Granular Activated Carbon With and Without Preozonation,
W84-03369 5F

DROUGHT
Some Spatial Characteristics of Drought Duration in the United States,
W84-03043 2B

Droughts and Famines in India - A Historical Perspective,
W84-03304 2B

Drought Spells Over North-Central India During the 1979 Southwest Monsoon,
W84-03308 2B

Analysis and Modeling of Palmer's Drought Index Series,
W84-03344 2B

Principles of Water Management Under Drought Conditions,
W84-03451 3F

DRY FARMING
Yield and Water Use Efficiency of Grain Sorghum in a Limited Irrigation-Dryland Farming System,
W84-03258 2I

Principles of Water Management Under Drought Conditions,
W84-03451 3F

DUCKWEED
Oxygen Regime in a Fishpond with Duckweeds (Lemnaceae) and Ceratophyllum,
W84-03195 2H

DYE RELEASES
Rhodamine WT Dye Losses in a Mountain Stream Environment,
W84-03399 5A

EAST GERMANY
Calcite Precipitation as a Natural Control Mechanism of Eutrophication,
W84-03496 2H

ECOLOGICAL EFFECTS
The Effect of Two Triazine Herbicides on the Productivity of Freshwater Marsh Periphyton,
W84-03119 5C

ECOLOGY
The Ecology of Lake Nakuru (Kenya); IV. Biomass and Distribution of Consumer Organisms,
W84-03149 2H

Ecology of Planktonic Larvae of Dreissena polymorpha (Pall.) in Lakes with Different Degree of Heating,
W84-03152 5C

ECONOMIC ASPECTS
New Business Opportunities,
W84-03050 6B

ECONOMIC EFFICIENCY
Transferable Discharge Permits and Economic Efficiency: The Fox River,
W84-03046 5D

ECONOMIC FACTORS
Estimating Residential Flood Control Benefits Using Implicit Price Equations,
W84-03392 4A

ECOSYSTEMS
Model of Adaptation of Active-Silt Ecosystem to Multicomponent Pollution,
W84-03026 2J

Material Balance of Aquatic Ecosystems and Chemical Binding (Vom Stoffhaushalt aquatischer Okosysteme zur Frage nach der chemischen Bindung),
W84-03186 2K

EDDY DIFFUSION
Chemical and Geochemical Studies of Lake Biel; II. A Chemical Approach to Lake Mixing,
W84-03168 2H

EFFLUENT POLISHING
Lagoon Effluent Polishing With Intermittent Sand Filters,
W84-03096 5D

EFFLUENTS
Possibilities and Limitations of Tracing Industrial Effluents in the Sea by Means of Capillary Chromatography,
W84-03158 5A

EGYPT
Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

EMISSION
Carbon Dioxide Emission and Carbon Accumulation in Coastal Wetlands,
W84-03136 5B

ENDANGERED SPECIES
Concentrations of Total Dissolved Solids Preferred or Avoided by Endangered Colorado River Fishes,
W84-03314 5C

ENERGY
The Altamira Hydro Complex in the Amazon Region,
W84-02995 6B

Microclimate at Arctic Tree Line 3. The Effects of Regional Advection on the Surface Energy Balance of Upland Tundra,
W84-03413 2C

ENGLAND
Community Structure in Some Southern English Streams: The Influence of Physicochemical Factors,
W84-03300 5C

ENVIRONMENT
Hydro-Electric Generation and the Environment (La Production Hydroelectrique et l'Environment),
W84-03361 6G

ENVIRONMENTAL EFFECTS
Periphyton Biomass and Species Composition in a Coastal Rainforest Stream in British Columbia: Effects of Environmental Changes Caused by Logging,
W84-03016 5C

Geothermal Effects on Stream Benthos: Separate Influences of Thermal and Chemical Components on Periphyton and Macroinvertebrates,
W84-03019 5C

Dugouts in Eastern South Dakota: Their Location in Relation to Basin Wetlands and Streams,
W84-03067 6G

Recultivation of Lake Mutek - Environmental and Fishery Aspects,
W84-03153 5A

Effects of Surface Mining on Aquatic Resources in North America,
W84-03197 5E

Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

Environmental Aspects of Clearing and Snagging,
W84-03473 6G

ENVIRONMENTAL PROTECTION
The 'Decade of the Environment' in the U.S.S.R.,
W84-02986 6G

EPILIMNION
The Impact of Zooplankton Feeding on the Epilimnetic Bacteria of a Eutrophic Lake,
W84-03290 2H

EPISODIC SEDIMENTATION
Observation of Episodic Sedimentation in a Tidal Inlet (Sabine Pass, Texas and Louisiana),
W84-03107 2L

EROSION
Soil Erosion in the Palouse: An Aerial Perspective,
W84-03052 2J

Rainfall Erosion Indices for Canada East of the Rocky Mountains,
W84-03225 2J

Estimates of Soil Erosion and Deposition for Some Saskatchewan Soils,
W84-03228 2J

Erosional Unloading and Fluid Pressures in Hydraulically 'Tight' Rocks,
W84-03236 8E

Analytical Solutions of Kinematic Equations for Erosion on a Plane. II. Rainfall of Finite Duration,
W84-03462 2J

EROSION CONTROL

Cross-Compliance to Enforce Soil and Water Conservation,
W84-03053 4D

What is Conservation Tillage,
W84-03058 4D

Conservation Tillage for Erosion Control,
W84-03059 4D

Irrigation + Dryland Farming + Limited Tillage: A Profitable Combination,
W84-03061 4D

Residue Management and Cultural Practices for a Semiarid Region,
W84-03063 3F

Residue Management to Reduce Furrow Erosion,
W84-03065 4D

Runoff Curve Numbers for Conservation Tillage,
W84-03069 4D

Field Verification of Runoff Curve Numbers for Fallow Rotations,
W84-03070 2E

Controlling Agricultural Soil Loss in Arkansas' North Lake Chicot Watershed: An Analysis of Benefits,
W84-03071 6B

Evaluating Riprapping and Other Streambank Stabilization Techniques,
W84-03220 4D

ESTIMATING

Simulation of a Rainfall Record for the Site of a New Agricultural Development: An Example from Northern Syria,
W84-03211 2B

An Evaluation of the Success of Morecs, a Meteorological Model, in Estimating Soil Moisture Deficits,
W84-03212 2G

Estimates of Soil Erosion and Deposition for Some Saskatchewan Soils,
W84-03228 2J

Recent Developments on the Probable Maximum Precipitation (PMP) Estimation in China,
W84-03347 2B

ESTUARIES

Chemistry of Dissolved and Particulate Material in the Estuary of the Rimouski River (Contribution a L'Etude Chimique du Materiel Dissous et Particulaire de L'Estuaire de la Riviere Rimouski),
W84-03108 2L

Trace Metals in the Gota River Estuary,
W84-03137 5B

Fluoride Pollution in French Rivers and Estuaries,
W84-03202 2L

Land Use Pressures on Coastal Estuaries in Atlantic Canada,
W84-03426 5B

ESTUARINE ENVIRONMENT

Spatial Distributions and Hypothetical Grazing Pressures of Zooplankton in the Tidal, Freshwater Potomac River,
W84-02967 2L

Environmental Gradients and Benthic Macroinvertebrate Distributions in a Shallow North Carolina Estuary,
W84-02977 2L

Acute Effects of Toxaphene and Its Sediment-Degraded Products on Estuarine Fish,
W84-03021 5C

The Reproductive Cycle of the Bay Scallop, Argopecten irradians irradians (Lamarck), in a Small Coastal Embayment on Cape Cod, Massachusetts,
W84-03039 2L

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Turbulence Measurements in Stratified and Well-mixed Estuarine Flows,
W84-03203 2L

Affinity of Hydrophobic Pollutants for Natural Estuarine Colloids in Aquatic Environments,
W84-03329 5B

Application of Nitrogen-Cycle Model to Manasquan Estuary,
W84-03476 2L

EUBACTERIA

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

EUTROPHIC LAKE

Production and Ecology of Benthic Chironomid Larvae (Diptera) in Lake Hayes, New Zealand, a Warm-monomictic Eutrophic Lake,
W84-02955 2H

EUTROPHIC LAKES

The Impact of Zooplankton Feeding on the Epilimnetic Bacteria of a Eutrophic Lake,
W84-03290 2H

Biomass and Production of Phyto- and Bacterio-Plankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

The Seasonal Variation of Organic Constituents in a Eutrophic Lake, Lake Suwa, Japan; Part II. Dissolved Organic Matter,
W84-03499 2H

EUTROPHICATION

The Coregones of Lake Neuchatel: Fishery Yield; Age and Growth of Individuals Caught by Professional Fishermen (Les coregones du lac de Neuchatel: rendement de la peche; age et croissance des individus captures par les pecheurs professionnels),
W84-03176 5C

Impact of Acidification and Eutrophication on Macrophyte Communities in Soft Waters in the Netherlands. I. Field Observations,
W84-03196 2H

Calcite Precipitation as a Natural Control Mechanism of Eutrophication,
W84-03496 2H

EVAPORATION

Direct Evaporation from Soil Under a Row Crop Canopy,
W84-03204 2D

Evaporation from the Irrigation Water, Foliage and Panicles of Paddy Rice in North-East Sri Lanka,
W84-03206 2D

Evaporation from Screened Class A Pans in a Semi-Arid Climate,
W84-03207 2D

Theoretical and Measured Evaporation Rates from an Exposed Piche Atmograph,
W84-03213 2D

A Discussion of the Relationships between the Principal Forms of the Combination Equation for Estimating Crop Evaporation,
W84-03217 2D

Intermittent Infiltration and Evaporation from Soil Columns,
W84-03227 2G

Biomass Production in Wheat in Relation to Evaporative Demand and Ambient Temperature,
W84-03310 2D

A Sensitivity Analysis of a Numerical Model for Estimating Evapotranspiration,
W84-03416 2D

Measurement of Evaporation by a Vapor Budget Technique,
W84-03421 2D

The Meteorological Office Rainfall and Evaporation Calculation System - MORECS,
W84-03442 2B

EVAPORATION RATE

Turfgrass Evapotranspiration. I. Factors Influencing Rate in Urban Environments,
W84-03266 2D

EVAPORATORS

A Preliminary Study on Scheduling Irrigation with Can Evaporimeters,
W84-03447 2D

EVAPORIMETERS

Theoretical and Measured Evaporation Rates from an Exposed Piche Atmograph,
W84-03213 2D

EVAPOTRANSPIRATION

The Direct Effect of Shelter on Evaporation Rates: Theory and An Experimental Test,
W84-03208 2D

Resistances to Evapotranspiration from a St. Augustinegrass Turf Canopy,
W84-03247 2D

Evapotranspiration and Yield Estimation of Spring Wheat From Canopy Temperature,
W84-03264 2D

Turfgrass Evapotranspiration. I. Factors Influencing Rate in Urban Environments,
W84-03266 2D

Relationships Between Leaf Water Potential, Canopy Temperature, and Evapotranspiration in Irrigated and Nonirrigated Alfalfa,
W84-03270 2D

A Sensitivity Analysis of a Numerical Model for Estimating Evapotranspiration,
W84-03416 2D

Crop Water Requirements for Rainfed and Irrigated Grain Corn in China,
W84-03435 2D

Estimation of Evapotranspiration at One Time-of-Day Using Remotely Sensed Surface Temperatures,
W84-03453 2D

Estimation of Daily Evapotranspiration from One Time-of-Day Measurements,
W84-03454 2D

EXPERIMENTAL DESIGN
Round Robin Investigation of Methods for the Recovery of Poliovirus from Drinking Water,
W84-03110 5A

EXSERTION
Role of Panicle Exsertion in Water Stress Induced Sterility,
W84-03284 2I

FATE OF POLLUTANTS
PCB Dynamics in Hudson River Striped Bass, II. Accumulation from Dietary Sources,
W84-03113 5B

Chemical Pathways from Stack Emissions to Surface Water,
W84-03383 5B

Endogenic Flux of Manganese to the Bottom of Lake Constance,
W84-03493 5B

FATTY ACIDS
Compositional Changes of Fatty Acids in Particulate Matter and Water Temperature, and Their Implications to the Seasonal Succession of Phytoplankton in a Hypereutrophic Lake, Lake Kasumigaura, Japan,
W84-03501 2H

FEEDING RATES
The Impact of Zooplankton Feeding on the Epilimnetic Bacteria of a Eutrophic Lake,
W84-03290 2H

FENS
Gradient Analysis of the Vegetation of the Byron-Bergen Swamp, a Rich Fen in Western New York,
W84-02973 2L

FERTILIZATION
Fertilizer and Salty Water Effects on Phaseolus,
W84-03239 3C

Turfgrass Growth, N Use, and Water Use under Soil Compaction and N Fertilization,
W84-03250 2I

Fertilizer Application and Irrigation Management of Broccoli Production and Fertilizer Use Efficiency,
W84-03252 3F

FIELD TESTS
Field Evaluation of a Water Relations Model for Soybean. I. Validity of Some Basis Assumptions,
W84-03245 2I

Field Evaluation of a Water Relations Model for Soybean, II. Diurnal Fluctuations,
W84-03246 2I

FILEFISH
Overlap and Pollution-induced Variability in the Feeding Habits of Filefish (Pisces: Monacanthidae) from Apalachee Bay, Florida,
W84-03132 5C

FILTRATION
Chlorination-Filtration for Iron and Manganese Removal,
W84-03142 5F

FINITE ELEMENT METHOD
A Numerical Procedure for Three-Dimensional Transient Free Surface Seepage,
W84-03467 2E

FISH
Lake Ontario's Fish - How They Almost Got Away,
W84-02985 5C

Delayed Toxicity of Carbofuran in Freshwater Teleosts, Channa punctatus (Bloch) and Anabas testudineus (Bloch),
W84-02992 5C

Acute Effects of Toxaphene and Its Sediment-Degraded Products on Estuarine Fish,
W84-03021 5C

Fish/Sediment Concentration Ratios for Organic Compounds,
W84-03034 5C

Role of Current on the Distribution of Juvenile Fishes in Reservoirs,
W84-03104 2H

Oogenesis of the Rybinsk Reservoir Bream, Abramis brama (Cyprinidae),
W84-03105 2H

PCB Dynamics in Hudson River Striped Bass, II. Accumulation from Dietary Sources,
W84-03113 5B

Research in Environmental Pollution; I. Determination of Polychlorinated Styrenes (PCS's) in Rhine Fish,
W84-03189 5A

Life History and Ecology of the Humpback Chub in the Little Colorado and Colorado Rivers of the Grand Canyon,
W84-03313 2H

Alterations in Gill Epithelial Morphology of Yearling Sunapee Trout Exposed to Acute Acid Stress,
W84-03317 5C

Chronic Effects of Coal-Liquid Dispersions on Fathead Minnows and Rainbow Trout,
W84-03319 5C

Model of PCB in the Lake Michigan Lake Trout Food Chain,
W84-03326 5B

FISH BEHAVIOR
Influence of Degree of Stream Turbulence on the Magnitude of the Critical Current Velocity for Fish,
W84-03027 8I

Hydraulic Characteristics of the Current That Produces Routes for Fish Movement,
W84-03029 8I

Biology of the Arctic Grayling, Thymallus arcticus (Thymallidae), in Ust' - Ilim Reservoir,
W84-03103 6G

The Influence of Flow Turbulence on Fish Behavior,
W84-03106 2H

Sublethal Effects of Treated Liquid Effluent From a Petroleum Refinery. III. Avoidance and Other Locomotor Responses of Rainbow Trout,
W84-03122 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. IV. Respiratory Movements and Coughing of Rainbow Trout,
W84-03123 5C

Overlap and Pollution-induced Variability in the Feeding Habits of Filefish (Pisces: Monacanthidae) from Apalachee Bay, Florida,
W84-03132 5C

Concentrations of Total Dissolved Solids Preferred or Avoided by Endangered Colorado River Fishes,
W84-03314 5C

Temperature Preference and Avoidance by Adult Razorback Suckers,
W84-03315 5C

Redd-Site Selection by Brook Trout and Brown Trout in Southwestern Ontario Streams,
W84-03320 2H

Reproduction by the Endangered Cui-ui in the Lower Truckee River,
W84-03321 2H

Phenol Tolerance in Populations of Mosquitofish from Polluted and Nonpolluted Waters,
W84-03322 5C

FISH FARMING
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

FISH FOOD
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

FISH FOOD ORGANISM
Trout-Zooplankton Relationships in Medical Lake, WA, Following Restoration by Aluminum Sulfate Treatment,
W84-02960 5G

FISH PONDS
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

FISH POPULATIONS
A New Approach to Estimating Populations by the Removal Method,
W84-03022 2H

A Stochastic Age-Structured Population Model of Striped Bass (Morone saxatilis) in the Potomac River,
W84-03023 2H

Fishery Status and Water Quality in Areas Affected by Acid Deposition,
W84-03387 5C

FISH TOXINS
Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

FISHERIES
A Model Relating the Results of Low pH Bioassay Experiments to the Fishery Status of Norwegian Lakes,
W84-03298 5C

Acid Rain, Catchment Characteristics and Fishery Status,
W84-03385 5C

FISHING
Fishing Rights: Indian Fishing Rights and Congress: the Salmon and Steelhead Conservation and Enhancement Act of 1980,
W84-02975 6E

A Time Series Approach to Forecasting Angling Activity at a Recreational Site Based on Past Successes,
W84-03024 6B

FLASH FLOODS
Focusing Mechanisms in the Texas Hill Country Flash Floods in 1978,
W84-03364 2B

FLOCCULENT SETTLING
Flocculent Settling in Quiescent Systems,
W84-03475 5D

FLOOD CONTROL
Operational Flood Routing for Hydroelectric Plants,
W84-02993 4A

Interpolation of Short Duration Rainfall from 24-Hour Rainfall in Lower Godavari Basin,
W84-03307 2B

Sensitivity of Outflow Peaks and Flood Stages to the Selection of Dam Breach Parameters and Simulation Models,
W84-03348 8D

Mathematical Modelling for Formation and Propagation of Floods in a Data-Deficient Basin,
W84-03349 2E

Estimating Residential Flood Control Benefits Using Implicit Price Equations,
W84-03392 4A

Regional Variability of Soil Characteristics for Flood and Low Flow Estimation,
W84-03440 2E

FLOOD FORECASTING
Long-Term Hydrologic Events from Short-Term Records,
W84-03340 2A

FLOOD PLAINS
Hydraulic Geometry of Floodplains,
W84-03351 2E

FLOOD ROUTING
Flood Routing Through a Flat, Complex Floodplain Using a One-Dimensional Unsteady Flow Computer Program,
W84-03395 8B

FLOODING
CRUE: A Model for Calculation the Probability of River Flooding (CRUE: Un Modele d'Estimation des Probabilites des Debits de Crue),
W84-03359 2E

FLOODPLAINS
Flood Routing Through a Flat, Complex Floodplain Using a One-Dimensional Unsteady Flow Computer Program,
W84-03395 8B

FLOODS
Effects of Late-Growing-Season Inundation on Tree Species in the Central Plains,
W84-03055 2E

FLOODWATER
Freshwater Impacts in Normally Hypersaline Marshes,
W84-03036 2L

FLORIDA
Limnological Features of Some Northwestern Florida Lakes,
W84-02971 2H

Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

Overlap and Pollution-induced Variability in the Feeding Habits of Filefish (Pisces: Monacanthidae) from Apalachee Bay, Florida,
W84-03132 5C

FLOW PATTERN
Contamination Analysis - Flow Nets and the Mass Transport Equation,
W84-03076 2F

FLOW VECTORS
Disaggregation Procedures for Generating Serially Correlated Flow Vectors,
W84-03412 2E

FLUCTUATIONS
Diffusivity-Based Flux of Phosphorus in Onondaga Lake,
W84-03097 5B

FLUID PRESSURES
Erosional Unloading and Fluid Pressures in Hydraulically 'Tight' Rocks,
W84-03236 8E

FLUORIDE
Fluoride in the Ground Water of Northeastern Ohio,
W84-03073 2F

Fluoride Pollution in French Rivers and Estuaries,
W84-03202 2L

FLUVIAL SANDS
Statistical and Stochastic Analyses of Hydraulic Conductivity and Particle-Size in a Fluvial Sand,
W84-03179 2G

FLY ASH
Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash,
W84-03374 5B

Use of 'The Capillary Barrier' as a Shield Against Groundwater Pollution from Fly-Ash Deposits,
W84-03378 5E

FOCUSING MECHANISMS
Focusing Mechanisms in the Texas Hill Country Flash Floods in 1978,
W84-03364 2B

FOLICOTE ANTITRANSPIRANT
Effect of Folicote Antitranspirant Application on Field Grain Yield of Moisture-Stressed Corn,
W84-03255 3F

FORAGE FISHES
Forage Fish Assemblages in the Brazos River Upstream and Downstream from Possum Kingdom Reservoir, Texas,
W84-02964 2H

FORECASTING
A Time Series Approach to Forecasting Angling Activity at a Recreational Site Based on Past Successes,
W84-03024 6B

Semi-Quantitative Precipitation Forecasts for Gomti Catchment by Synoptic Analogue Method,
W84-03309 2B

FOREST SOILS
Soil Erosion on Subarctic Forest Slopes,
W84-03056 2J

FOREST STREAMS
Preliminary Measurements of Primary Production and Community Respiration in a Forest Stream in Hong Kong,
W84-03492 2H

FORESTRY
Marine Log Transportation and Handling Systems in British Columbia: Impacts on Coastal Management,
W84-03424 6G

FORESTS
The Derivation and Validation of a New Model for the Interception of Rainfall by Forests,
W84-03205 2I

FOSSIL FUEL
Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry,
W84-03390 5B

FOUNTAINS
Diatoms in Fountains, Reservoirs and Some Other Humid and Dry Localities in Rome, Italy,
W84-03311 2H

FOX RIVER
Transferable Discharge Permits and Economic Efficiency: The Fox River,
W84-03046 5D

FROZEN GROUND
Transport of Water in Frozen Soil. II. Effects of Ice on the Transport of Water Under Isothermal Conditions,
W84-03458 2G

FUNGI
Nickel Toxicity to Estuarine/Marine Fungi and its Amelioration by Magnesium in Sea Water,
W84-02988 5C

FUTURE PLANNING
The Third Wave in Water Quality Management,
W84-02980 6E

GANGES RIVER
A Quantitative Study of Phytoplankton of the River Ganges at Bhagalpur, India,
W84-03151 2H

GAS CHROMATOGRAPHY
Quantitation of Environmental Contaminants by Fused-Silica Capillary Column Gas Chromatography-Mass Spectrometry with Multiple Internal Standards and On-Column Injection,
W84-03161 5A

GAS-FILM COEFFICIENTS
Gas-Film Coefficients for Streams,
W84-03090 2H

GAS-PHASE STRIPPING
Evaluation of Sampling Methods for the Determination of Trace Organics in Water,
W84-03163 5A

GEOCHEMISTRY
The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W. Norway,
W84-03135 2K

Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry,
W84-03390 5B

The Geochemical Record of Major Cations and Trace Metals in a Productive Lake; Analysis of Thinly Sliced Sediment Samples Characterised by Diatom Stratigraphy,
W84-03500 2H

GEOHYDROLOGY
Chemical Composition of Water-Bodies in the English Lake District: Relationships Between

Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

Geohydrology and Hydrochemistry of the Dakota Aquifer, Central United States,
W84-03394 2F

GEOLOGIC FRACTURES
A Stochastic Model of a Fractured Rock Conditioned by Measured Information,
W84-03414 8E

GEORGIA
Primary Productivity Studies During Early Years of West Point Reservoir, Alabama-Georgia,
W84-03299 5C

GEOTHERMAL AQUIFERS
Convection in an Aquifer Above a Layer of Heated Impermeable Bedrock,
W84-03480 2F

GEOTHERMAL FLUIDS
Geothermal Effects on Stream Benthos: Separate Influences of Thermal and Chemical Components on Periphyton and Macroinvertebrates,
W84-03019 5C

GEOTHERMAL STUDIES
Thermohaline Convection in Flowing Groundwater,
W84-03465 2F

Convection in an Aquifer Above a Layer of Heated Impermeable Bedrock,
W84-03480 2F

GLACIAL AQUIFERS
Remote Sensing and Geophysical Investigations of Glacial Buried Valleys in Northeastern Kansas,
W84-03079 2F

GLACIERS
Variations of the Stocking (Te Wae Wae) Glacier, Mount Cook, and Climatic Relationships,
W84-03484 2C

GLACIOLOGY
Climatic Effects on the Recession of the Franz Josef Glacier,
W84-03483 2C

GLAUCOUS
Yield, Water Relations, Gas Exchange, and Surface Reflectances of Near-Isogenic Wheat Lines Differing in Glaucousness,
W84-03277 2I

GLYCINEBETAINE
Genotypic Variation for Glycinebetaine Accumulation by Cultivated and Wild Barley in Relation to Water Stress,
W84-03278 2I

GOTA RIVER
Trace Metals in the Gota River Estuary,
W84-03137 5B

GRAIN SORGHUM
Yield and Water Use Efficiency of Grain Sorghum in a Limited Irrigation-Dryland Farming System,
W84-03258 2I

GRAND RIVER
The Influence of the Grand River on Phytoplankton Near the Northeastern Shore of Lake Erie during 1979,
W84-03489 5C

GRANTS
Funding Municipal Wastewater Facilities in Georgia,
W84-03233 6C

GRASSLANDS
The Relationship Between Nutrient Availability, Shoot Biomass and Species Richness in Grassland and Wetland Communities,
W84-02974 2I

GRAVITY FLOW
Gravity Wastewater Collection Systems Optimization,
W84-03092 5B

GRAZING
Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream,
W84-03057 5B

GRAZING LAND
Relationship of Runoff and Soil Loss to Ground Cover of Native and Reclaimed Grazing Land,
W84-03256 2E

GREASE
Oil and Grease in Urban Stormwaters,
W84-03470 5B

GREAT LAKE
Macrobenthic Fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania,
W84-03125 2H

Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

GREAT PLAINS
Irrigation in the Great Plains,
W84-03452 3F

GROUND COVER
Relationship of Runoff and Soil Loss to Ground Cover of Native and Reclaimed Grazing Land,
W84-03256 2E

GROUNDWATER
Sporhase v. Nebraska ex rel. Douglas: A Call for Ground Water Legislation,
W84-03003 6E

Sporhase v. Nebraska ex rel. Douglas: State Control of Water Under the Constraints of the Commerce Clause,
W84-03010 6E

Sporhase v. Nebraska ex rel. Douglas: Does the Dormant Commerce Clause Really Limit the Power of a State to Forbid (1) the Export of Water and (2) the Creation of a Water Right for Use in Another State,
W84-03013 6E

Thermal Impact of Residential Ground-Water Heat Pumps,
W84-03072 2F

Fluoride in the Ground Water of Northeastern Ohio,
W84-03073 2F

Relationships Between Ground-water Silica, Total Dissolved Solids, and Specific Electrical Conductivity,
W84-03082 5A

Transformations of Tetrachloroethene and Trichloroethene in Microcosms and Groundwater,
W84-03367 5B

Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

GROUNDWATER CONTAMINATION
Model of Ion Equilibrium in Aqueous Solutions of Fly Ash in the Context of Prediction of Ground and Surface Water Contamination,
W84-03381 5B

GROUNDWATER IRRIGATION
Engineering Economic Analyses of Artificial Recharge in the Columbia Basin Project, Washington,
W84-03402 4B

GROUNDWATER MANAGEMENT
Management of Groundwater Through Mandatory Conservation,
W84-03234 6E

Optimum Management of a Regional Confined Aquifer,
W84-03461 2F

GROUNDWATER MOUNDING
Ground-Water Mounding Beneath a Large Leaching Bed,
W84-03083 4B

GROUNDWATER MOVEMENT
Contamination Analysis - Flow Nets and the Mass Transport Equation,
W84-03076 2F

A Simple Analytical Solution for the Boussinesq One-Dimensional Groundwater Flow Equation,
W84-03409 2F

Finite-Element Methods Based on a Transport Velocity Representation for Groundwater Motion,
W84-03420 2F

Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

On the Application of the Boundary Layer Approximation for the Simulation of Density Stratified Flows in Aquifers,
W84-03463 2F

Thermohaline Convection in Flowing Groundwater,
W84-03465 2F

GROUNDWATER POLLUTION
Groundwater Monitoring Well Primer,
W84-03048 4B

TOC Determinations in Ground Water,
W84-03074 5A

Impact of Land Use on Ground-water Quality in Southern Delaware,
W84-03077 5B

Use of 'The Capillary Barrier' as a Shield Against Groundwater Pollution from Fly-Ash Deposits,
W84-03378 5E

GROUNDWATER POTENTIAL
Thermal Impact of Residential Ground-Water Heat Pumps,
W84-03072 2F

Remote Sensing and Geophysical Investigations of Glacial Buried Valleys in Northeastern Kansas,
W84-03079 2F

GROUNDWATER RECHARGE
Ground-Water Mounding Beneath a Large Leaching Bed,
W84-03083 4B

GROUNDWATER STORAGE
A Land-Use Policy Based on Water Supply,
W84-03398 6F

GROWTH
A Study on the Growth of Salvinia molesta Mitchell in Relation to Light and Temperature, W84-03194 5C

Wheat Root Growth, Grain Yield and Water Uptake as Influenced by Soil Water Regime and Depth of Nitrogen Placement in a Loamy Sand Soil, W84-03445 2I

GWENT LEVELS
The Macroinvertebrate Fauna of the Drainage Channels of the Gwent Levels, South Wales, W84-03289 5C

GYPSIFEROUS-SODIC SOIL
Crop Yield - Irrigation Relationships in a Gypsiferous-Sodic Soil, W84-03248 3F

HABITATS
The Effects of Surface Geology and Stream Size on Freshwater Mussel (Bivalvia, Unionidae) Distribution in Southeastern Michigan, U.S.A., W84-03291 2H

Redd-Site Selection by Brook Trout and Brown Trout in Southwestern Ontario Streams, W84-03320 2H

HANDLING
The Handling and Disposal of Coal Ash in the CEGB in Relation to the Aqueous Environment, W84-03373 5E

HARBORS
PCB Contamination in and around New Bedford, Mass, W84-03031 5B

HARDNESS
Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters, W84-03111 5C

HEAVY METALS
The Influence of Flow Conditions on the Removal of Heavy Metals in the Primary Sedimentation Process, W84-02991 5D

Turbidity Interferes with Accuracy in Heavy Metals Concentrations, W84-03041 5B

Investigations on Heavy Metal Speciation in Natural Waters by Voltammetric Procedures, W84-03185 5B

Bonding Forms of Heavy Metals in Sediments and Sludges: Sorption/Mobilization, Chemical Extraction and Bioavailability (Bindungsformen von Schwermetallen in Sedimenten und Schlammen: Sorption/Mobilisierung, chemische Extraktion und Bioverfugbarkeit), W84-03188 5B

Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash, W84-03374 5B

Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms, W84-03380 5A

Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry, W84-03390 5B

HERBICIDES
The Effect of Two Triazine Herbicides on the Productivity of Freshwater Marsh Periphyton, W84-03119 5C

Affinity of Hydrophobic Pollutants for Natural Estuarine Colloids in Aquatic Environments, W84-03329 5B

HIGH PRESSURE
Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup, W84-03078 5D

HILL COUNTRY
Focusing Mechanisms in the Texas Hill Country Flash Floods in 1978, W84-03364 2B

HIPLEX
Augmentation of Rainfall from Summer Cumulus Clouds, W84-03448 3B

HONG KONG
Preliminary Measurements of Primary Production and Community Respiration in a Forest Stream in Hong Kong, W84-03492 2H

HUMAN CELLS
Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium, W84-03114 5C

HUMAN DISEASES
Waterborne Disease Outbreaks - 1946-1980: A Thirty-Five-Year Perspective, W84-03368 5C

HUMIC ACIDS
The Contribution of Humic Substances to the Acidity of Colored Natural Waters, W84-03332 2K

HUMIC SUBSTANCES
On the Coordination Between Metals and Aquatic Humic Material (Zur koordinativen Bindung von Metallionen an Gewasserhuminstoffe), W84-03187 5B

HYDROBIOLOGY
Hydrobiological Study of a Harnessed River: The Verdon (Etude Hydrobiologique d'une Riviere Amenagee: le Verdon Les Lacs de Barrage et les Troncons de Cours d'Eau a Debit Regule), W84-03360 6G

HYDROCARBONS
Sources and Transport of Hydrocarbons in the Green-Duwamish River, Washington, W84-03327 5B

HYDRODYNAMICS
Hydrodynamics of the Lake of Geneva, W84-03169 2H

Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich- und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle), W84-03170 2H

HYDROELECTRIC DEVELOPMENT
Hydroelectric Development and Wilderness Conflict in South-West Tasmania, W84-03324 6G

HYDROELECTRIC PLANTS
Hydro-Electric Generation and the Environment (La Production Hydroelectrique et l'Environment), W84-03361 6G

HYDROELECTRIC POWER
The Northwest's Hydroelectric Heritage: Prologue to the Pacific Northwest Electric Power Planning and Conservation Act, W84-03030 6G

HYDROGEN ION CONCENTRATION
Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters, W84-03111 5C

A Model Relating the Results of Low pH Bioassay Experiments to the Fishery Status of Norwegian Lakes, W84-03298 5C

Throughfall pH: Effect of Precipitation Timing and Amount, W84-03401 5B

Acid Snowpack Chemistry in Pennsylvania, 1979-81, W84-03405 5B

HYDROLOGIC BUDGET
Water Balance of Three Irrigated Crops on Fine-Textured Soils of the Riverine Plain, W84-03238 2I

HYDROLOGIC DATA
Long-Term Hydrologic Events from Short-Term Records, W84-03340 2A

HYDROLOGIC DELINEATION
Hydrologic Delineation of Nonpoint Source Contributing Areas, W84-03086 5B

HYDROLOGIC MODELS
Modelling of Hydrologic Processes in a Small Urbanized Hillslope Basin with Comments on the Effects of Urbanization, W84-03337 2A

Application of Environmental Isotope Tracers to Modeling in Hydrology, W84-03339 2A

Long-Term Hydrologic Events from Short-Term Records, W84-03340 2A

Identification and Prediction of Nonlinear Hydrologic Systems by the Filter-Separation Autoregressive (AR) Method: Extension to Hourly Hydrologic Data, W84-03343 2A

How to Use a Single-Parameter Conceptual Model in Hydrology (Que peut-on faire en hydrologie avec un modele conceptuel a un seul parametre), W84-03357 2A

The Soil-Moisture Zone in a Physically-Based Hydrologic Model, W84-03459 2G

HYDROLOGIC PROPERTIES
Qualitative Properties of Internal Motions of Lake Geneva (Qualitative Eigenschaften Interner Bewegungen des Genfersees), W84-03172 1A

HYDROLOGIC SYSTEMS
Effects of Surface Mining on Aquatic Resources in North America, W84-03197 5B

HYDROLOGY
Hydrologic Control of Lake Susceptibility to Acidification, W84-03017 2K

Research on Watershed Hydrology at the University of Illinois,
W84-03333 2A

Hydraulic Geometry of Floodplains,
W84-03351 2E

Hydrology of a Basin with Extreme Rainfalls-Cropp River, New Zealand,
W84-03482 2E

HYPERTROPHIC LAKES
Nitrogen Fixation and Phosphorus Turnover in a Hypertrophic Prairie Lake,
W84-03015 2H

HYPOLIMNION
Mixing Processes in Lakes: Mechanisms and Ecological Relevance,
W84 03167 2H

Elevated Concentrations of Humic Substances in a Seasonally Anoxic Hypolimnion: Evidence for Co-Accumulation with Iron,
W84-03488 5B

HYSTERESIS
Numerical Analysis of Soil Water Movement under Conditions of Rapid Intermittency of Water Application,
W84-03418 2G

ICE FORMATION
Comments Concerning 'Convection Patterns in a Pond',
W84-02981 2C

INDIA
A Quantitative Study of Phytoplankton of the River Ganges at Bhagalpur, India,
W84-03151 2H

INDIAN FISHING RIGHTS
Fishing Rights: Indian Fishing Rights and Congress: the Salmon and Steelhead Conservation and Enhancement Act of 1980,
W84-02975 6E

INDIAN WATER RIGHTS
Water Rights: Aboriginal Water Use and Water Law in the Southwestern United States: Why the Reserved Rights Doctrine was Inappropriate,
W84-02976 6E

INDIANA
Color Patterns and Water Table Levels in Some Indiana Soils,
W84-03181 2G

INDUSTRIAL WASTES
Industrial Waste Elimination - An Optimal Solution,
W84-03040 5D

Turbidity Interferes with Accuracy in Heavy Metals Concentrations,
W84-03041 5B

Possibilities and Limitations of Tracing Industrial Effluents in the Sea by Means of Capillary Chromatography,
W84-03158 5A

Cleaner Technology: Who Gains from Pollution Prevention,
W84-03365 6B

Aquatic Effects of Wet Ash Disposal and Wet Limestone Scrubber Systems,
W84-03375 5C

INFILTRATION
Intermittent Infiltration and Evaporation from Soil Columns,
W84-03227 2G

Renovation of Wastewater at the 23rd Avenue Rapid Infiltration Project,
W84-03428 5D

INFRARED THERMOMETRY
Effect of Wind on the Crop Water Stress Index Derived by Infrared Thermometry,
W84-03265 2I

INJECTION WELLS
Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

INTERMITTENT FILTERS
Lagoon Effluent Polishing With Intermittent Sand Filters,
W84-03096 5D

INTERNAL STANDARDS
Quantitation of Environmental Contaminants by Fused-Silica Capillary Column Gas Chromatography-Mass Spectrometry with Multiple Internal Standards and On-Column Injection,
W84-03161 5A

INTERNATIONAL ENVIRONMENTAL EFFECTS
Acid Precipitation - An International Environmental Problem,
W84-03382 2K

INVERTEBRATES
The Natural History of a Nearctic Temporary Pond in Ontario with Remarks on Continental Variation in Such Habitats,
W84-02952 2H

Alkalinity, Discharge, Average Velocity, and Invertebrate Drift Concentration in Subarctic Alaskan Streams,
W84-02969 2H

IONS
Chemical Composition of Water-Bodies in the English Lake District: Relationships Between Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

IRAQ
Quality Changes in Baghdad Canals and Irrigation,
W84-03148 5B

IRELAND
The Physical Limnology of Augher Lough (Northern Ireland),
W84-03294 2H

IRON
The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W. Norway,
W84-03135 2K

Chlorination-Filtration for Iron and Manganese Removal,
W84-03142 5F

A Simplified 1,10-Phenanthroline Technique Suitable for the Determination of Dissolved Iron in Remote Souces of Water,
W84-03292 5A

IRON REMOVAL
Overland Flow for Iron Removal from Potable Water,
W84-03143 5F

IRRIGATION
Irrigation Decisions Simplified with Electronics and Soil Water Sensors,
W84-03183 2G

Water Balance of Three Irrigated Crops on Fine-Textured Soils of the Riverine Plain,
W84-03238 2I

Root Distribution and Water Use Efficiency of Alfalfa as Influenced by Depth of Irrigation,
W84-03241 2I

Tillage and Cultural Management of Irrigated Potatoes,
W84-03242 2G

Yield and Water Use Efficiency of Grain Sorghum in a Limited Irrigation-Dryland Farming System,
W84-03258 2I

Irrigation of Soybean Genotypes During Reproductive Ontogeny. I. Agronomic Responses,
W84-03279 2I

Irrigation of Soybean Genotypes During Reproductive Ontogeny II. Yield Component Responses,
W84-03280 2I

Biomass Production in Wheat in Relation to Evaporative Demand and Ambient Temperature,
W84-03310 2D

IRRIGATION EFFECTS
Irrigation Regime Effects on Some Physiological Responses of Potato,
W84-03244 2I

Crop Yield - Irrigation Relationships in a Gypsiferous-Sodic Soil,
W84-03248 3F

Alfalfa Responses to Irrigation Treatment and Environment,
W84-03249 2I

Leaf and Canopy Temperatures of Pearl Millet Genotypes Under Irrigated and Nonirrigated Conditions,
W84-03251 3F

Response of Soybean Cultivars to Irrigation of a Clay Soil,
W84-03268 3F

Yield and Water Relations of Pearl Millet Genotypes under Irrigated and Nonirrigated Conditions,
W84-03269 2I

Relationships Between Leaf Water Potential, Canopy Temperature, and Evapotranspiration in Irrigated and Nonirrigated Alfalfa,
W84-03270 2D

Effects of Wastewater Irrigation and Plant and Row Spacing on Soybean Yield and Development,
W84-03271 3C

IRRIGATION MANAGEMENT
Fertilizer Application and Irrigation Management of Broccoli Production and Fertilizer Use Efficiency,
W84-03252 3F

IRRIGATION PRACTICES
Irrigation + Dryland Farming + Limited Tillage: A Profitable Combination,
W84-03061 4D

Residue Management to Reduce Furrow Erosion,
W84-03065 4D

Computer Schedules Irrigation,
W84-03230 3F

Numerical Analysis of Soil Water Movement under Conditions of Rapid Intermittency of Water Application,
W84-03418 2G

IRRIGATION PROGRAM
Irrigation Regime Effects on Some Physiological Responses of Potato,
W84-03244 2I

IRRIGATION SCHEDULING
A Preliminary Study on Scheduling Irrigation with Can Evaporimeters,
W84-03447 2D

Irrigation in the Great Plains,
W84-03452 3F

IRRIGATION WATER
Effect of Soluble Species Released from Soil Sources on the Composition of Soil and Drainage Solutions,
W84-03180 5B

Using Blowdown Water to Irrigate Crops,
W84-03218 3C

IRRIGATIONS EFFECTS
Effects of Irrigation on Accumulation of Soil and Symbiotically Fixed N by Soybean Grown on a Norfolk Loamy Sand,
W84-03260 2I

ISOLINES
Root System Characteristics of Two Soybean Isolines Undergoing Water Stress Conditions,
W84-03274 2I

ISOTOPIC TRACERS
Application of Environmental Isotope Tracers to Modeling in Hydrology,
W84-03339 2A

ITALY
Precipitation over Northern Italy: A Description by Means of Principal Component Analysis,
W84-03146 2B

Diatoms in Fountains, Reservoirs and Some Other Humid and Dry Localities in Rome, Italy,

KEPONE
Effects of Accumulated Dietary Kepone on Spot (Leiostomus xanthurus),
W84-03115 5C

KERNEL FUNCTION
The Kernel Function for Watershed Runoff Modeling,
W84-03335 2E

KOREA
Development of Water Resources in Korea,
W84-02999 6B

Crop Water Requirements for Rainfed and Irrigated Grain Corn in China,
W84-03435 2D

KRIGING
Kriged Estimates of Transmissivity in the Mesilla Bolson, New Mexico,
W84-03397 2F

LABORATORY STUDIES
Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash,
W84-03374 5B

LACLOCHE MOUNTAINS
Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

LAGRANGIAN METEOROLOGY
Lagrangian Meteorology and Measurements of Acidic Precipitation at Washington, D.C.,
W84-03286 5B

LAKE BALDEGG
Mixing Processes in Lakes: Mechanisms and Ecological Relevance,
W84-03167 2H

LAKE BIEL
Chemical and Geochemical Studies of Lake Biel; II. A Chemical Approach to Lake Mixing,
W84-03168 2H

LAKE BREITER LUCIN
Calcite Precipitation as a Natural Control Mechanism of Eutrophication,
W84-03496 2H

LAKE EMBAYMENTS
Phytoplankton Modeling in the Embayments of Lakes,
W84-03095 2H

LAKE ERIE
Assessing Land-Use Regulations in Coastal Wetlands: The Case of the Long Point Area, Lake Erie, Ontario,
W84-03425 6F

The Influence of the Grand River on Phytoplankton Near the Northeastern Shore of Lake Erie during 1979,
W84-03489 5C

LAKE EVAPORATION
Measurement of Evaporation by a Vapor Budget Technique,
W84-03421 2D

LAKE FISHERIES
Recultivation of Lake Mutek - Environmental and Fishery Aspects,
W84-03153 5A

LAKE GENEVA
Hydrodynamics of the Lake of Geneva,
W84-03169 2H

Qualitative Properties of Internal Motions of Lake Geneva (Qualitative Eigenschaften Interner Bewegungen des Genfersees),
W84-03172 1A

PCB and DDT Concentrations of Sediments from Swiss Shoreline of Lake Geneva, Switzerland, (Concentrations en PCB et DDT des Sediments Superficiels de la Rive Suissec du Lac Leman),
W84-03173 5B

LAKE HAYES
Production and Ecology of Benthic Chironomid Larvae (Diptera) in Lake Hayes, New Zealand, a Warm-monomictic Eutrophic Lake,
W84-02955 2H

LAKE HURON
Retrospective Analysis of the Response of Saginaw Bay, Lake Huron, to Reductions in Phosphorus Loadings,
W84-03033 5C

LAKE LEMAN
Hydrodynamics of the Lake of Geneva,
W84-03169 2H

LAKE LUGANO
Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich- und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle),
W84-03170 2H

LAKE MUTEK
Recultivation of Lake Mutek - Environmental and Fishery Aspects,
W84-03153 5A

LAKE NAKURU
The Ecology of Lake Nakuru (Kenya); IV. Biomass and Distribution of Consumer Organisms,
W84-03149 2H

The Ecology of Lake Nakuru (Kenya); V. Production and Consumption of Consumer Organisms,
W84-03150 2H

LAKE NEUCHATEL
The Coregones of Lake Neuchatel: Fishery Yield; Age and Growth of Individuals Caught by Professional Fishermen (Les coregones du lac de Neuchatel: rendement de la peche; age et croissance des individus captures par les pecheurs professionnels),
W84-03176 5C

LAKE ONTARIO
Lake Ontario's Fish - How They Almost Got Away,
W84-02985 5C

LAKE RESTORATION
Trout-Zooplankton Relationships in Medical Lake, WA, Following Restoration by Aluminum Sulfate Treatment,
W84-02960 5G

Recultivation of Lake Mutek - Environmental and Fishery Aspects,
W84-03153 5A

Possible Measures for the Restoration of Lake Sempach (Mogliche Massnahmen zur Restaurierung des Sempachersees),
W84-03174 5G

LAKE SEDIMENTS
Decomposition of Organic Matter in Lake Sediments,
W84-03032 2J

Carbonate Mineralogy of Lake Sediments and Surrounding Soils I. Blackstrap Lake,
W84-03223 2K

Carbonate Mineralogy of Lake Sediments and Surrounding Soils. 2. The Qu'Apelle Lakes,
W84-03224 2H

Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry,
W84-03390 5B

Cadmium Adsorption by Aerobic Lake Sediments,
W84-03477 5B

LAKE SEMPACH
Possible Measures for the Restoration of Lake Sempach (Mogliche Massnahmen zur Restaurierung des Sempachersees),
W84-03174 5G

LAKE SORELL
Macrobenthic Fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania,
W84-03125 2H

LAKE SUPERIOR
Preliminary Study of the Diversion of 283 cu m/s (10,000 cfs) from Lake Superior to the Missouri River Basin,
W84-03356 4B

LAKE SUWA
The Seasonal Variation of Organic Constituents in a Eutrophic Lake, Lake Suwa, Japan; Part II. Dissolved Organic Matter,
W84-03499 2H

LAKE TYSTRUP
Biomass and Production of Phyto- and Bacterio-Plankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

LAKE VANSJO
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

LAKE ZURICH
Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich- und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle),
W84-03170 2H

LAKES
Growth Kinetics of Microcystis aeruginosa (Kutz) Kutz as a Basis for Modelling its Population Dynamics,
W84-02954 2I

The Desmids and Physical Characteristics of 100 Lakes in Northeastern Pennsylvania,
W84-02962 2H

Hydrologic Control of Lake Susceptibility to Acidification,
W84-03017 2K

Reaeration and Vertical Diffusion of Lake Oxygen,
W84-03098 2H

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Toxicity of Cyanobacteria in Dutch Lakes and Reservoirs,
W84-03117 2H

Numerical Models for the Currents Simulation of a Lake (Mathematische Modelle zur Simulation von Zirkulationsstromungen in Einem See),
W84-03171 2H

Chemical Composition of Water-Bodies in the English Lake District: Relationships Between Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

A Model Relating the Results of Low pH Bioassay Experiments to the Fishery Status of Norwegian Lakes,
W84-03298 5C

Transport in Lake Water Quality Modeling,
W84-03469 2H

Light Attenuation in Onondaga Lake, NY, USA, 1978,
W84-03497 2H

Compositional Changes of Fatty Acids in Particulate Matter and Water Temperature, and Their Implications to the Seasonal Succession of Phytoplankton in a Hypereutrophic Lake, Lake Kasumigaura, Japan,
W84-03501 2H

Comparative Study of the Nutrient-Salts of Lake Edku (Egypt) Before and After the Construction of Asswan's High Dam in 1958 and 1969,
W84-03504 6G

LAND RECLAMATION
Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

LAND USE
Wherever the Water Flows: Lyon Applies the Public Trust to Non-Tidal Water,
W84-03004 6E

Impact of Land Use on Ground-water Quality in Southern Delaware,
W84-03077 5B

A Land-Use Policy Based on Water Supply,
W84-03398 6F

Assessing Land-Use Regulations in Coastal Wetlands: The Case of the Long Point Area, Lake Erie, Ontario,
W84-03425 6F

Land Use Pressures on Coastal Estuaries in Atlantic Canada,
W84-03426 5B

Oil and Grease in Urban Stormwaters,
W84-03470 5B

LANDFILLS
Landfill Leachate Treatment,
W84-03427 5D

LARVAE
Influence of Deteriorating Water Quality on Growth and Development of Chum Salmon (Oncorhynchus keta) Larvae in a Japanese-Style Keeper Channel,
W84-03020 5C

Ecology of Planktonic Larvae of Dreissena polymorpha (Pall.) in Lakes with Different Degree of Heating,
W84-03152 5C

Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

LAUREL CREEK RESERVOIR
Changes in the Chironomid (Diptera: Chironomidae) Fauna of Laurel Creek Reservoir, Waterloo, Ontario,
W84-02965 2H

LAW ENFORCEMENT
Private Enforcement of Federal Antipollution Laws Through Citizen Suits: A Model,
W84-03002 6F

LEACHATES
Effect of Soluble Species Released from Soil Sources on the Composition of Soil and Drainage Solutions,
W84-03180 5B

Landfill Leachate Treatment,
W84-03427 5D

LEACHING
Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash,
W84-03374 5B

Studies on the Leaching and Weathering Processes of Coal Ashes,
W84-03377 5E

LEACHING REQUIREMENT
Leaching Requirement for Salinity Control III. Barley, Cowpea, and Celery,
W84-03431 3C

LEAD
Lead in Drinking Water-Investigation of a Corrosive Water Supply,
W84-02983 5F

LEAF GROWTH
Alfalfa Stem and Leaf Growth During Water Stress,
W84-03263 2I

LEAF TEMPERATURES
Leaf and Canopy Temperatures of Pearl Millet Genotypes Under Irrigated and Nonirrigated Conditions,
W84-03251 3F

Stress Measurement Using Foliage Temperatures,
W84-03257 2D

LEAVES
Relationships Between Leaf Water Potential, Canopy Temperature, and Evapotranspiration in Irrigated and Nonirrigated Alfalfa,
W84-03270 2D

Significance of Accelerated Leaf Senescence at Low Water Potentials for Water Loss and Grain Yield in Maize,
W84-03285 2I

LEGAL ASPECTS
Fishing Rights: Indian Fishing Rights and Congress: the Salmon and Steelhead Conservation and Enhancement Act of 1980,
W84-02975 6E

Water Rights: Aboriginal Water Use and Water Law in the Southwestern United States: Why the Reserved Rights Doctrine was Inappropriate,

Constitutional Law - Water Law - Constitutionality of Water Export Bans and Limitations on Interstate Water Allocation. Sporhase v. Nebraska ex rel. Douglas, - U.S. -, 102 S. Ct. 3456 (1982),
W84-03011 6E

EGUMES
Wetting and Maturity Effects on the Yield and Quality of Legume Hay,
W84-03253 2I

ENTIC ENVIRONMENT
Pelagic Diatom Populations in Lentic Freshwater Microcosms,
W84-02953 2H

IGHT PENETRATION
Light Attenuation in Onondaga Lake, NY, USA, 1978,
W84-03497 2H

IMNOLOGY
Limnological Features of Some Northwestern Florida Lakes,
W84-02971 2H

The Physical Limnology of Augher Lough (Northern Ireland),
W84-03294 2H

ITTORAL ENVIRONMENT
Production and Distribution of Benthic Microalgae in the Littoral Sediments of Mikolajskie Lake,
W84-03133 2H

IVER WEIGHTS
Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

OAD DISTRIBUTION
Calibration of NPS Model Loading Factors,
W84-03093 5B

OAMY SAND
Effects of Irrigation on Accumulation of Soil and Symbiotically Fixed N by Soybean Grown on a Norfolk Loamy Sand,
W84-03260 2I

OCAL GOVERNMENTS
Water Supply: A State or Local Problem,
W84-03232 6F

LOG HANDLING
Marine Log Transportation and Handling Systems in British Columbia: Impacts on Coastal Management,
W84-03424 6G

LOGGING
Periphyton Biomass and Species Composition in a Coastal Rainforest Stream in British Columbia: Effects of Environmental Changes Caused by Logging,
W84-03016 5C

LONGITUDINAL DISPERSION
Longitudinal Dispersion in Natural Streams,
W84-03087 5A

LOTIC ENVIRONMENT
The Recovery of the Biotic Community in a Lotic Freshwater Habitat after Extensive Destruction by Chlorine,
W84-02951 5C

LOW FLOW
Low Flow Synthesis by Computer; Part One,
W84-02996 2E

Low Flow Synthesis by Computer; Part Two,
W84-02997 2E

An Attempt to Pre-Determine Low Water Flows in Streams Losing Water in Calcareous Regions: Example of the Tille River Between Til-Chatel and Spoy (21) (Essai de Predetermination des Debits d'Etiage Sur les Cours d'Eau Presentant des Pertes en Region Calcaire. L'Exemple de la Tille Entre Til-Chatel et Spoy (21)),
W84-03362 2E

MACROINVERTEBRATES
Benthic Macroinvertebrates and Water Quality Assessment: Some Toxicological Considerations,
W84-03118 5C

The Colonization of Ball-Clay Ponds by Macroinvertebrates and Macrophytes,
W84-03301 2H

MACROINVERTIBRATES
The Macroinvertebrate Fauna of the Drainage Channels of the Gwent Levels, South Wales,
W84-03289 5C

MACROPHYTES
The Colonization of Ball-Clay Ponds by Macroinvertebrates and Macrophytes,
W84-03301 2H

MAGNESIUM
Magnesium Nutrition and Grain Yield of Maize Having Low Water Potential,
W84-03272 2I

MAINTENANCE
Keeping Old Reservoirs Active,
W84-03140 8A

MAIZE YIELD
Magnesium Nutrition and Grain Yield of Maize Having Low Water Potential,
W84-03272 2I

Significance of Accelerated Leaf Senescence at Low Water Potentials for Water Loss and Grain Yield in Maize,
W84-03285 2I

MANASQUAN ESTUARY
Application of Nitrogen-Cycle Model to Manasquan Estuary,
W84-03476 2L

MANGANESE
The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W. Norway,
W84-03135 2K

Chlorination-Filtration for Iron and Manganese Removal,
W84-03142 5F

Endogenic Flux of Manganese to the Bottom of Lake Constance,
W84-03493 5B

MANGROVE SWAMPS
Mangrove Distribution in Northwestern Australia in Relationship to Regional and Local Freshwater Seepage,
W84-02972 2L

MANSOUR
Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

MARSHES
Distribution and Abundance of Zooplankton in an Alkaline Freshwater Marsh in Northumberland County, Pennsylvania,
W84-02956 2L

Dynamics of Physical and Chemical Parameters in Okefenokee Swamp,
W84-02968 2L

MASS SPECTROMETRY
Quantitation of Environmental Contaminants by Fused-Silica Capillary Column Gas Chromatography-Mass Spectrometry with Multiple Internal Standards and On-Column Injection,
W84-03161 5A

MASS TRANSPORT
Contamination Analysis - Flow Nets and the Mass Transport Equation,
W84-03076 2F

Model of Mississippi River Pool: Mass Transport,
W84-03084 2E

MASSACHUSETTS
The Reproductive Cycle of the Bay Scallop, Argopecten irradians irradians (Lamarck), in a Small Coastal Embayment on Cape Cod, Massachusetts,
W84-03039 2L

MASURIAN LAKELAND
Thermal Conditions of Bottom Sediments in Five Shallow Lakes of Masurian Lakeland,
W84-03134 2H

MATHEMATICAL EQUATIONS
Quantitative Expression of Soil-Moisture Function for Remote Indication,
W84-03028 2G

A Simple Analytical Solution for the Boussinesq One-Dimensional Groundwater Flow Equation,
W84-03409 2F

Extremal Hypotheses for River Regime: An Illusion of Progress,
W84-03417 8B

Analytical Solutions of Kinematic Equations for Erosion on a Plane. II. Rainfall of Finite Duration,
W84-03462 2J

MATHEMATICAL MODELS
Model of Mississippi River Pool: Dissolved Oxygen,
W84-03085 2H

Models for Water Reuse and Wastewater Planning,
W84-03091 5D

Phytoplankton Modeling in the Embayments of Lakes,
W84-03095 2H

Diffusion Model for Degrading Channels,
W84-03166 8B

Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich- und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle),
W84-03170 2H

Numerical Models for the Currents Simulation of a Lake (Mathematische Modelle zur Simulation von Zirkulationsstromungen in Einem See),
W84-03171 2H

How to Use a Single-Parameter Conceptual Model in Hydrology (Que peut-on faire en hydrologie avec un modele conceptuel a un seul parametre),
W84-03357 2A

CRUE: A Model for Calculation the Probability of River Flooding (CRUE: Un Modele d'Estimation des Probabilites des Debits de Crue),
W84-03359 2E

A Dynamic Model of Basin Sediment Yield,
W84-03415 2J

A Sensitivity Analysis of a Numerical Model for Estimating Evapotranspiration,
W84-03416 2D

Multilevel Withdrawal and Water Quality,
W84-03472 2H

MATHEMATICAL STUDIES

Some Spatial Characteristics of Drought Duration in the United States,
W84-03043 2B

MATURITY

Wetting and Maturity Effects on the Yield and Quality of Legume Hay,
W84-03253 2I

MEADOWS

Water Conditions in Central Caucasian Subalpine Meadow,
W84-03025 2G

MEASURING INSTRUMENTS

Rainfall Analysis by Power Transformation,
W84-03044 2B

Measuring the Market for Water Instruments,
W84-03049 7B

Theoretical and Measured Evaporation Rates from an Exposed Piche Atmograph,
W84-03213 2D

Seasonal Estimates of Transpiration from a Millet Crop Using a Porometer,
W84-03214 2D

Statistical Assessment of Some Errors in Thermocouple Hygrometric Water Potential Measurement,
W84-03215 7B

Automated Rain Sampler for Trace Organic Substances,
W84-03330 5A

MEDICAL LAKE

Trout-Zooplankton Relationships in Medical Lake, WA, Following Restoration by Aluminum Sulfate Treatment,
W84-02960 5G

MERCURY

Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

Transport of Airborne Mercury Emitted by Coal Burning into Aquatic Systems,
W84-03386 5B

MESILLA BOLSON

Kriged Estimates of Transmissivity in the Mesilla Bolson, New Mexico,
W84-03397 2F

METABOLIZING ENZYMES

Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

METALS

On the Coordination Between Metals and Aquatic Humic Material (Zur koordinativen Bindung von Metallionen an Gewasserhuminstoffe),
W84-03187 5B

Metals in the Pacific Sargassum Algae as Related to Water Pollution Monitoring (Metally v Sostave Tikhookeanskikh Sargassovykh Vodoroslei v Svyazi s Problemoi Monitoringa Eagryaeneniya Vod),
W84-03312 5A

Processes Controlling Metal Ion Attenuation in Acid Mine Drainage Streams,
W84-03331 5B

METHANE BACTERIA

Separation of Bacteria from a Methanogenic Wastewater Population by Utilizing a Self-Generating Percoll Gradient,
W84-03164 5D

MEUSE RIVER

Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

The Algal Communities of the Upper Belgian Meuse and the Water Quality: A Synthesis at Fall 1981 (Les Communautes Algales de la Haute Meuse Belge et la Qualite de ses Eauz: Un Bilan a l'Automene 1981),
W84-03127 2H

MICROBIAL UTILIZATION

Microbial Heterotrophic Utilization of Dissolved Organic Matter in a Piedmont Stream,
W84-03295 5B

MICROCLIMATE

Soybean Water Status and Canopy Microclimate Relationships at Four Row Spacings,
W84-03273 2I

MICROCOSMS

Transformations of Tetrachloroethene and Trichloroethene in Microcosms and Groundwater,
W84-03367 5B

MICROCYSTIS

Growth Kinetics of Microcystis aeruginosa (Kutz) Kutz as a Basis for Modelling its Population Dynamics,
W84-02954 2I

MINE WASTES

Runoff Fraction and Pollution Levels in Runoff from a Waste Rock Dump Undergoing Pyritic Oxidation,
W84-02987 5B

MINERALOGY

Carbonate Mineralogy of Lake Sediments and Surrounding Soils I. Blackstrap Lake,
W84-03223 2K

MINERALS

Effect of Soluble Species Released from So
Sources on the Composition of Soil and Drain
age Solutions,
W84-03180 5I

MISSISSIPPI RIVER POOL

Model of Mississippi River Pool: Mass Trans
port,
W84-03084 2I

Model of Mississippi River Pool: Dissolve
Oxygen,
W84-03085 2I

MISSOURI RIVER BASIN

Preliminary Study of the Diversion of 283 cu m
s (10,000 cfs) from Lake Superior to the Missou
River Basin,
W84-03356 4I

MIXING

Mixing Processes in Lakes: Mechanisms and Ec
ological Relevance,

Mathematical Modelling for Formation and
Propagation of Floods in a Data-Deficient Basin
W84-03349 2E

A Model of the Dispersion of Soluble of Pseudo-Soluble Substances in Waterways. Application to the case of the Seine Upstream of Paris (Modelisation de la Dispersion des Substances Solubles ou Pseudo-Solubles dans un Cours d. Eau. Application au Cas de la Seine a l'Amont de Paris),
W84-03358 5A

A Stochastic Model of a Fractured Rock Conditioned by Measured Information,
W84-03414 8E

River Flow Reconstructions and Their Use, Part 1,
W84-03423 2E

Use of Dissolved Oxygen Modeling Results in the Management of River Quality,
W84-03430 5G

Delayed Yield. An Exact Quasi-Three Dimensional Model for Free-Aquifers,
W84-03460 2F

Transport in Lake Water Quality Modeling,
W84-03469 2H

IODEL TESTING
Comparison of Basin Performance Modeling Techniques,
W84-03088 5A

IOISTURE STRESS
Effect of Folicote Antitranspirant Application on Field Grain Yield of Moisture-Stressed Corn,
W84-03255 3F

A Method For Inducing Controlled Moisture Stress on Seedlings,
W84-03267 2I

Moisture Stress and N Redistribution in Soybean,
W84-03275 2I

IONITORING
Appraising Wastewater Discharge Compliance Levels,
W84-03047 6B

Groundwater Monitoring Well Primer,
W84-03048 4B

Measuring the Market for Water Instruments,
W84-03049 7B

Effects of Industrial Boiler Blowdown Discharges on Streams,
W84-03051 5C

Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

Determination of Chlorine Dioxide, Chlorine, Chlorite and Chlorate in Water,
W84-03141 5A

Metals in the Pacific Sargassum Algae as Related to Water Pollution Monitoring (Metally v Sostave Tikhookeanskikh Sargassovykh Vodoroslei v Svyazi s Problemoi Monitoringa Eagryaeneniya Vod),
W84-03312 5A

Infrared Remote Sensing for Monitoring Rainfall,
W84-03455 2B

MONOCULTURE
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

MORTALITY
Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

MOUNTAIN LAKES
Comparative Water Chemistry of Four Lakes in Rocky Mountain National Park,
W84-03393 2H

MT. SAINT HELENS
Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

MULTIVARIABLE ANALYSIS
Use of Time-Series Analysis to Demonstrate Advection Rates of Different Variables in a Small Lake,
W84-03102 2H

MULTIVARIATE ANALYSIS
Relationships among Chemical, Physical, and Biological Indices along River Continua Based on Multivariate Analyses,
W84-03494 2H

MUNICIPAL WASTES
Soil-Aquifer Treatment Using Primary Effluent,
W84-03429 5D

MUNICIPAL WATER
Cascade Model of Monthly Municipal Water Use,
W84-03408 6D

MUSSELS
The Effects of Surface Geology and Stream Size on Freshwater Mussel (Bivalvia, Unionidae) Distribution in Southeastern Michigan, U.S.A.,
W84-03291 2H

NATIONAL PARKS
Water Rights for Expanded Uses on Federal Reservations,
W84-03235 6E

NATURAL STREAMS
Longitudinal Dispersion in Natural Streams,
W84-03087 5A

NAVIGABLE WATERS
North Dakota Century Code section 47-01-15: Determining North Dakota's Interest in the Beds of Navigable Waters,
W84-03012 6E

NEBRASKA
Sporhase v. Nebraska ex rel. Douglas: A Call for Ground Water Legislation,
W84-03003 6E

Sporhase v. Nebraska ex rel. Douglas: Does the Dormant Commerce Clause Really Limit the Power of a State to Forbid (1) the Export of Water and (2) the Creation of a Water Right for Use in Another State,
W84-03013 6E

NETHERLANDS
Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

NEW BRUNSWICK
Land Use Pressures on Coastal Estuaries in Atlantic Canada,
W84-03426 5B

NEW JERSEY
Application of Nitrogen-Cycle Model to Manasquan Estuary,
W84-03476 2L

NEW MEXICO
Kriged Estimates of Transmissivity in the Mesilla Bolson, New Mexico,
W84-03397 2F

NEW TERRITORIES
Preliminary Measurements of Primary Production and Community Respiration in a Forest Stream in Hong Kong,
W84-03492 2H

NEW YORK
Gradient Analysis of the Vegetation of the Byron-Bergen Swamp, a Rich Fen in Western New York,
W84-02973 2L

History of Phosphorus Loading to Onondaga Lake,
W84-03471 5B

NEW ZEALAND
Production and Ecology of Benthic Chironomid Larvae (Diptera) in Lake Hayes, New Zealand, a Warm-monomictic Eutrophic Lake,
W84-02955 2H

Variations of the Stocking (Te Wae Wae) Glacier, Mount Cook, and Climatic Relationships,
W84-03484 2C

Soil Morphology and Water Regimes in 3 Recent Alluvial Soils on the Taieri Plains, South Island, New Zealand,
W84-03485 2G

NICKEL
Nickel Toxicity to Estuarine/Marine Fungi and its Amelioration by Magnesium in Sea Water,
W84-02988 5C

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

NIMBUS-7
The Utilization of Nimbus-7 SMMR Measurements to Delineate Rainfall over Land,
W84-03147 2B

NITORGEN
Turfgrass Growth, N Use, and Water Use under Soil Compaction and N Fertilization,
W84-03250 2I

NITRATES
Impact of Land Use on Ground-water Quality in Southern Delaware,
W84-03077 5B

Relationship of Nitrate Concentrations to Distance of Well Screen Openings Below Casing Water Levels,
W84-03403 5F

NITRITE
Spectrophotometric Determination of Nitrite in Natural Waters by Flow Injection Analysis,
W84-03109 5A

NITROGEN
Bioassays with Stigeoclonium Kutz. (Chlorophyceae) to Identify Nitrogen and Phosphorus Limitations,
W84-03193 5A

Nitrogen Losses from a Louisiana Gulf Coast Salt Marsh,
W84-03199 2L

Effects of Irrigation on Accumulation of Soil and Symbiotically Fixed N by Soybean Grown on a Norfolk Loamy Sand,
W84-03260 2I

Moisture Stress and N Redistribution in Soybean,
W84-03275 2I

Wheat Root Growth, Grain Yield and Water Uptake as Influenced by Soil Water Regime and Depth of Nitrogen Placement in a Loamy Sand Soil,
W84-03445 2I

NITROGEN CYCLE
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

Application of Nitrogen-Cycle Model to Manasquan Estuary,
W84-03476 2L

NITROGEN FIXATION
Nitrogen Fixation and Phosphorus Turnover in a Hypertrophic Prairie Lake,
W84-03015 2H

Alfalfa Response to Soil Water Deficits. III. Nodulation and N2 Fixation,
W84-03283 2I

NITROGEN FIXING
Nitrogen Fixing Activity of Water Stressed Siratro,
W84-03259 2I

NONPARAMETRIC TESTS
Nonparametric Tests for Trend in Water Quality,
W84-03419 5A

NONPOINT POLLUTION SOURCES
Hydrologic Delineation of Nonpoint Source Contributing Areas,
W84-03086 5B

Loading Functions for Predicting Nutrient Losses from Complex Watersheds,
W84-03400 5B

NONPOINT POLLUTION SUBMODEL
Calibration of NPS Model Loading Factors,
W84-03093 5B

NORTH AMERICA
Historical Changes in Acid Precipitation and Heavy Metals Deposition Originating from Fossil Fuel Combustion in Eastern North America as Revealed by Lake Sediment Geochemistry,
W84-03390 5B

NORTH DAKOTA
North Dakota Century Code section 47-01-15: Determining North Dakota's Interest in the Beds of Navigable Waters,
W84-03012 6E

NORWAY
The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W. Norway,
W84-03135 2K

Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

A Model Relating the Results of Low pH Bioassay Experiments to the Fishery Status of Norwegian Lakes,
W84-03298 5C

NOVA SCOTIA
Land Use Pressures on Coastal Estuaries in Atlantic Canada,
W84-03426 5B

NUTRIENT REMOVAL
Growth of Salvinia molesta as Affected by Water Temperature and Nutrition; II. Effects of Phosphorus Level,
W84-03192 5C

NUTRIENTS
Soil and Nutrient Runoff Losses with In-Row, Chisel-Planted Soybeans,
W84-03062 2J

Bioassays with Stigeoclonium Kutz. (Chlorophyceae) to Identify Nitrogen and Phosphorus Limitations,
W84-03193 5A

Loading Functions for Predicting Nutrient Losses from Complex Watersheds,
W84-03400 5B

Comparative Study of the Nutrient-Salts of Lake Edku (Egypt) Before and After the Construction of Asswan's High Dam in 1958 and 1969,
W84-03504 6G

OHIO
Fluoride in the Ground Water of Northeastern Ohio,
W84-03073 2F

Mine Drainage and Rock Type Influences on Eastern Ohio Stream Water Quality,
W84-03391 5B

OIL
Oil and Grease in Urban Stormwaters,
W84-03470 5B

OKEFENOKEE SWAMP
Dynamics of Physical and Chemical Parameters in Okefenokee Swamp,
W84-02968 2L

ONONDAGA LAKE
Diffusivity-Based Flux of Phosphorus in Onondaga Lake,
W84-03097 5B

History of Phosphorus Loading to Onondaga Lake,
W84-03471 5B

ONTARIO
Changes in the Chironomid (Diptera: Chironomidae) Fauna of Laurel Creek Reservoir, Waterloo, Ontario,
W84-02965 2H

Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

Assessing Land-Use Regulations in Coastal Wetlands: The Case of the Long Point Area, Lake Erie, Ontario,
W84-03425 6F

The Influence of the Grand River on Phytoplankton Near the Northeastern Shore of Lake Erie during 1979,
W84-03489 5C

OPERATING POLICIES
A Binary State DP Algorithm for Operation Problems of Multireservoir Systems,
W84-03407 6A

OPTIMIZATION
Optimization of a Tree-Like Water-Suppl System,
W84-03353 6

Some Mathematical Problems in Optimize Planning of a Water-Resources System,
W84-03354 6

OPTIMUM DEVELOPMENT PLANS
Models for Water Reuse and Wastewater Pla ning,
W84-03091 5

Gravity Wastewater Collection Systems Optim zation,
W84-03092 5

ORGANIC CARBON
TOC Determinations in Ground Water,
W84-03074 5

ORGANIC COMPOUNDS
Potential Phytotoxicity of Diquat Accumulate by Aquatic Plants and Sediments,
W84-02990 5

Delayed Toxicity of Carbofuran in Freshwat Teleosts, Channa punctatus (Bloch) and Anab testudineus (Bloch),
W84-02992 5

Fish/Sediment Concentration Ratios for Orga ic Compounds,
W84-03034 5

A Column Technique for Determining Sorptio of Organic Solutes on the Lithological Structu of Aquifers,
W84-03129 5

Investigation of a Comprehensive Approach f Trace Analysis of Dissolved Organic Substanc in Water,
W84-03162 5

Evaluation of Sampling Methods for the Dete mination of Trace Organics in Water,
W84-03163 5

Automated Rain Sampler for Trace Organ Substances,
W84-03330 5

ORGANIC MATTER
Nonreversible Sorption of Phenolic Compoun by Sediment Fractions: The Role of Sedime Organic Matter,
W84-03035 5

Water Retention Equations and Their Relatio ship to Soil Organic Matter and Particle Si Distribution for Disturbed Samples,
W84-03226 2

OVERLAND FLOW
Overland Flow for Iron Removal from Potab Water,
W84-03143 5

OWNERSHIP OF BEDS
North Dakota Century Code section 47-01-1 Determining North Dakota's Interest in the Be of Navigable Waters,
W84-03012 6

OWNERSHIP OF WATER
Sporhase v. Nebraska: The Muddying of Co merce Clause Waters,
W84-03007 6

OXBOW LAKES
Spectral Measurements of Surface Suspend Matter in an Oxbow Lake in the Lower Miss sippi Valley,
W84-02970 7

OXYGEN BALANCE
Oxygen Regime in a Fishpond with Duckweeds (Lemnaceae) and Ceratophyllum,
W84-03195 2H

OXYGEN TRANSFER
Effect of Rain on Surface Reaeration,
W84-03468 2K

OXYOZOSYNTHESIS
Sludge Treatment by Oxyozosynthesis Stops Ocean Dumping,
W84-03190 5D

PALAEMON PACIFICUS
The Influences of Temperature Variations and Thermal Pollution on Various Aspects of the Biology of the Prawn Palaemon Pacificus (Stimpson),
W84-03371 5C

PANICLE
Role of Panicle Exsertion in Water Stress Induced Sterility,
W84-03284 2I

PARTICLE SIZE
Statistical and Stochastic Analyses of Hydraulic Conductivity and Particle-Size in a Fluvial Sand,
W84-03179 2G

PARTICLES
The Importance of Attachment to Particles for Planktonic Bacteria,
W84-03495 2H

PARTICULATE MATTER
Chemistry of Dissolved and Particulate Material in the Estuary of the Rimouski River (Contribution a L'Etude Chimique du Materiel Dissous et Particulaire de L'Estuaire de la Riviere Rimouski),
W84-03108 2L

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

PARTICULATES
Sewage Sludge Coagulation and Settling in Seawater,
W84-03328 5B

PATH OF POLLUTANTS
Contamination Analysis - Flow Nets and the Mass Transport Equation,
W84-03076 2F

Transport of Airborne Mercury Emitted by Coal Burning into Aquatic Systems,
W84-03386 5B

Sulphur and Chloride Deposition and Ecosystem Transport in a Strongly Acidified Lake Watershed,
W84-03388 5B

Critical Point Method for Mixing Zones in Rivers,
W84-03478 5B

PEARL MILLET
Leaf and Canopy Temperatures of Pearl Millet Genotypes Under Irrigated and Nonirrigated Conditions,
W84-03251 3F

Yield and Water Relations of Pearl Millet Genotypes under Irrigated and Nonirrigated Conditions,
W84-03269 2I

PENNSYLVANIA
The Desmids and Physical Characteristics of 100 Lakes in Northeastern Pennsylvania,
W84-02962 2H

Acid Snowpack Chemistry in Pennsylvania, 1979-81,
W84-03405 5B

PERENNIAL RYEGRASS
Perennial Ryegrass Growth, Water Use, and Soil Aeration Status under Soil Compaction,
W84-03240 2I

PERFORMANCE EVALUATION
Comparison of Basin Performance Modeling Techniques,
W84-03088 5A

PERIPHYTON
The Effect of Two Triazine Herbicides on the Productivity of Freshwater Marsh Periphyton,
W84-03119 5C

PERMEABILITY COEFFICIENT
Tracing Subsurface Flow on Roadcuts on Steep, Forested Slopes,
W84-03177 2G

A Transient Method for Measuring Soil Water Diffusivity and Unsaturated Hydraulic Conductivity,
W84-03178 2G

Statistical and Stochastic Analyses of Hydraulic Conductivity and Particle-Size in a Fluvial Sand,
W84-03179 2G

Effect of Mixed Cation Solutions on Hydraulic Soil Properties,
W84-03432 2G

Use of Soil Survey Data to Select Measurement Techniques for Hydraulic Conductivity,
W84-03437 2G

PERMITS
Wetlands Preservation, Fish and Wildlife Protection, and 404 Regulations: A Response,
W84-03009 6E

Transferable Discharge Permits and Economic Efficiency: The Fox River,
W84-03046 5D

PESTICIDES
Delayed Toxicity of Carbofuran in Freshwater Teleosts, Channa punctatus (Bloch) and Anabas testudineus (Bloch),
W84-02992 5C

PETROLEUM REFINERY EFFLUENT
Sublethal Effects of Treated Liquid Effluent From a Petroleum Refinery. III. Avoidance and Other Locomotor Responses of Rainbow Trout,
W84-03122 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. V. Reproduction of Daphnia Pulex and Overall Evaluation,
W84-03124 5C

PETROLEUM REFINERY EFFLUENTS
Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. IV. Respiratory Movements and Coughing of Rainbow Trout,
W84-03123 5C

PHASEOLUS
Fertilizer and Salty Water Effects on Phaseolus,
W84-03239 3C

PHENOLS
Nonreversible Sorption of Phenolic Compounds by Sediment Fractions: The Role of Sediment Organic Matter,
W84-03035 5B

Chronic Effects of Coal-Liquid Dispersions on Fathead Minnows and Rainbow Trout,
W84-03319 5C

Phenol Tolerance in Populations of Mosquitofish from Polluted and Nonpolluted Waters,
W84-03322 5C

PHOSPHORUS
Retrospective Analysis of the Response of Saginaw Bay, Lake Huron, to Reductions in Phosphorus Loadings,
W84-03033 5C

Diffusivity-Based Flux of Phosphorus in Onondaga Lake,
W84-03097 5B

Possible Measures for the Restoration of Lake Sempach (Mogliche Massnahmen zur Restaurierung des Sempachersees),
W84-03174 5G

Material Balance of Aquatic Ecosystems and Chemical Binding (Vom Stoffhaushalt aquatischer Okosysteme zur Frage nach der chemischen Bindung),
W84-03186 2K

Growth of Salvinia molesta as Affected by Water Temperature and Nutrition; II. Effects of Phosphorus Level,
W84-03192 5C

Bioassays with Stigeoclonium Kutz. (Chlorophyceae) to Identify Nitrogen and Phosphorus Limitations,
W84-03193 5A

A High-Speed Liquid Chromatography of Phosphorus in Anoxic Waters Occurring in a Bay Using Solvent Extraction of Molybdoheteropoly Yellow,
W84-03288 5A

History of Phosphorus Loading to Onondaga Lake,
W84-03471 5B

PHOSPHORUS REMOVAL
Nitrogen Fixation and Phosphorus Turnover in a Hypertrophic Prairie Lake,
W84-03015 2H

Chemical Optimization of Tertiary Contact Filters,
W84-03479 5D

PHYSICAL PROPERTIES
Dynamics of Physical and Chemical Parameters in Okefenokee Swamp,
W84-02968 2L

PHYSICOCHEMICAL PROPERTIES
A Study on the Macro-Zoobenthos and the Physico-chemical Characteristics of the Bottom of Bakhira Lake, Uttar Pradesh, India,
W84-02959 2H

PHYSIOCHEMICAL PROPERTIES
Community Structure in Some Southern English Streams: The Influence of Physicochemical Factors,
W84-03300 5C

PHYSIOLOGICAL ECOLOGY
Irrigation Regime Effects on Some Physiological Responses of Potato,
W84-03244 2I

PHYSIOLOGICAL RESPONSE
Contaminant Accumulation and Physiological Response in Rainbow Trout (Salmo gairdneri) Reared on Naturally Contaminated Diets,
W84-03018 5C

PHYTOPLANKTON
Phytoplankton Modeling in the Embayments of Lakes,
W84-03095 2H

PHYTOPLANKTON

A Quantitative Study of Phytoplankton of the River Ganges at Bhagalpur, India,
W84-03151 2H

Biomass and Production of Phyto- and Bacterio-Plankton in Eutrophic Lake Tystrup, Denmark,
W84-03296 2H

The Influence of the Grand River on Phytoplankton Near the Northeastern Shore of Lake Erie during 1979,
W84-03489 5C

PHYTOTOXICITY
Potential Phytotoxicity of Diquat Accumulated by Aquatic Plants and Sediments,
W84-02990 5C

PIEDMONT
Microbial Heterotrophic Utilization of Dissolved Organic Matter in a Piedmont Stream,
W84-03295 5B

PIEZOMETERS
The Investigation of Aquifer Parameters Using Multiple Piezometers,
W84-03075 2F

PLANKTON
Plankton Productivity and Biomass in a Tributary of the Upper Chesapeake Bay. I. Importance of Size-Fractionated Phytoplankton Productivity, Biomass and Species Composition in Carbon Export,
W84-03200 2L

The Importance of Attachment to Particles for Planktonic Bacteria,
W84-03495 2H

PLANNING
Rural Water-Supply and Sanitation Planning: The Use of Socioeconomic Preconditions in Project Identification,
W84-03355 6A

Cleaner Technology: Who Gains from Pollution Prevention,
W84-03365 6B

PLANT COMMUNITIES
The Nature Reserve s'Gravendel (Retie, Belgium); I. Phytosociological Description in Relation to Moisture and Soil Conditions (Het Natuurgebied 's-Gravendel (Retie, Belgie); I. Fitosociologische Beschrijving in Relatie tot Vochtigheid en Bodem),
W84-03128 2L

PLANT GROWTH
Water Stress and Water-Use Efficiency in Field Grown Wheat: A Comparison of Its Efficiency with That of C4 Plants,
W84-03209 2I

Perennial Ryegrass Growth, Water Use, and Soil Aeration Status under Soil Compaction,
W84-03240 2I

Turfgrass Growth, N Use, and Water Use under Soil Compaction and N Fertilization,
W84-03250 2I

Alfalfa Response to Soil Water Deficits. I. Growth, Forage Quality, Yield, Water Use, and Water-Use Efficiency,
W84-03281 2I

PLANT PHYSIOLOGY
Comparative Physiology and Water Relations of Two Corn Hybrids During Water Stress,
W84-03276 2I

PLANT WATER POTENTIAL
Magnesium Nutrition and Grain Yield of Maize Having Low Water Potential,
W84-03272 2I

Soybean Water Status and Canopy Microclimate Relationships at Four Row Spacings,
W84-03273 2I

Yield, Water Relations, Gas Exchange, and Surface Reflectances of Near-Isogenic Wheat Lines Differing in Glaucousness,
W84-03277 2I

Alfalfa Response to Soil Water Deficits. II. Plant Water Potential, Leaf Conductance, and Canopy Temperature Relationships,
W84-03282 2D

PLANT WATER POTENTIALS
Simulating the Effects of Weather Variables and Soil Water Potential on a Corn Canopy Temperature,
W84-03210 3F

POLAND
Recultivation of Lake Mutek - Environmental and Fishery Aspects,
W84-03153 5A

Ecological Characteristics of Polisaprobic Section of the Vistula River below Warsaw,
W84-03154 5C

Oxygen Consumption and Survival of Asellus aquaticus L. (Crustacea) in Vistula River Section Highly Polluted by Municipal Sewage,
W84-03155 5C

POLICY
A Land-Use Policy Based on Water Supply,
W84-03398 6F

POLICY MAKING
The Politics of Wetland Conservation: A Wildlife View,
W84-03054 6E

POLIOVIRUS
Round Robin Investigation of Methods for the Recovery of Poliovirus from Drinking Water,
W84-03110 5A

POLITICAL ASPECTS
Administration Loses Its Umbrella Against Standfast Acid Rain Policy,
W84-03000 5G

The Politics of Wetland Conservation: A Wildlife View,
W84-03054 6E

POLLUTANT IDENTIFICATION
TOC Determinations in Ground Water,
W84-03074 5A

Spectrophotometric Determination of Nitrite in Natural Waters by Flow Injection Analysis,
W84-03109 5A

A Column Technique for Determining Sorption of Organic Solutes on the Lithological Structure of Aquifers,
W84-03129 5A

Coprostanol Distribution from Sewage Discharge into Sarasota Bay, Florida,
W84-03130 5B

Baker's Yeast Assay Procedure for Testing Heavy Metal Toxicity,
W84-03131 5A

Determination of Chlorine Dioxide, Chlorine, Chlorite and Chlorate in Water,
W84-03141 5A

Quantitation of Environmental Contaminants by Fused-Silica Capillary Column Gas Chromatography-Mass Spectrometry with Multiple Internal Standards and On-Column Injection,
W84-03161 5A

Research in Environmental Pollution; I. Determination of Polychlorinated Styrenes (PCS's) in Rhine Fish,
W84-03189 5A

Charr as Indicators of Pollution,
W84-03198 5C

A High-Speed Liquid Chromatography of Phosphorus in Anoxic Waters Occurring in a Bay Using Solvent Extraction of Molybdoheteropoly Yellow,
W84-03288 5A

A Simplified 1,10-Phenanthroline Technique Suitable for the Determination of Dissolved Iron in Remote Souces of Water,
W84-03292 5A

POLLUTANTS
The Microtox* as an Alternative Assay in the Acute Toxicity Assessment of Water Pollutants,
W84-03120 5C

POLLUTION LOAD
Reliability of River-Treatment Plant Systems,
W84-03474 5C

POLYCHLORINATED BIPHENYLS
PCB Contamination in and around New Bedford, Mass,
W84-03031 5B

Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

PCB Dynamics in Hudson River Striped Bass, II. Accumulation from Dietary Sources,
W84-03113 5B

Identification and Determination of Polychlorinated Biphenyls by High-Resolution Gas Chromatography,
W84-03157 5A

PCB and DDT Concentrations of Sediments from Swiss Shoreline of Lake Geneva, Switzerland, (Concentrations en PCB et DDT des Sediments Superficiels de la Rive Suissec du Lac Leman),
W84-03173 5B

POLYCHLORINATED STYRENES
Research in Environmental Pollution; I. Determination of Polychlorinated Styrenes (PCS's) in Rhine Fish,
W84-03189 5A

POLYCULTURE
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

PONDS
The Natural History of a Nearctic Temporary Pond in Ontario with Remarks on Continental Variation in Such Habitats,
W84-02952 2H

Dugouts in Eastern South Dakota: Their Location in Relation to Basin Wetlands and Streams,
W84-03067 6G

Oxygen Regime in a Fishpond with Duckweeds (Lemnaceae) and Ceratophyllum,
W84-03195 2H

The Colonization of Ball-Clay Ponds by Macroinvertebrates and Macrophytes,
W84-03301 2H

POPULATION
Soil Water and Population Influence on Hybrid Sunflower Yield and Uniformity of Stand,
W84-03261 2I

POPULATION DENSITY
Estimates of Microbial Populations Involved in the N Cycle and Their Activity in Water and Sediments of Fish Farming Ponds under Mono- and Polyculture Systems in India,
W84-02958 2H

POPULATION DYNAMICS
Pelagic Diatom Populations in Lentic Freshwater Microcosms,
W84-02953 2H

Growth Kinetics of Microcystis aeruginosa (Kutz) Kutz as a Basis for Modelling its Population Dynamics,
W84-02954 2I

Forage Fish Assemblages in the Brazos River Upstream and Downstream from Possum Kingdom Reservoir, Texas,
W84-02964 2H

Changes in the Chironomid (Diptera: Chironomidae) Fauna of Laurel Creek Reservoir, Waterloo, Ontario,
W84-02965 2H

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. V. Reproduction of Daphnia Pulex and Overall Evaluation,
W84-03124 5C

POROSITY
Direct Parameter Identification of Fractured Porous Medium,
W84-03457 2G

POSSUM KINGDOM RESERVOIR
Forage Fish Assemblages in the Brazos River Upstream and Downstream from Possum Kingdom Reservoir, Texas,
W84-02964 2H

POTABLE WATER
U.K. Pushes R and D to Meet Potable Water Demand,
W84-03001 6D

Round Robin Investigation of Methods for the Recovery of Poliovirus from Drinking Water,
W84-03110 5A

Overland Flow for Iron Removal from Potable Water,
W84-03143 5F

POTATO
Irrigation Regime Effects on Some Physiological Responses of Potato,
W84-03244 2I

POTATOES
Tillage and Cultural Management of Irrigated Potatoes,
W84-03242 2G

POTOMAC RIVER
Spatial Distributions and Hypothetical Grazing Pressures of Zooplankton in the Tidal, Freshwater Potomac River,
W84-02967 2L

A Stochastic Age-Structured Population Model of Striped Bass (Morone saxatilis) in the Potomac River,
W84-03023 2H

Potomac River Streamflow Since 1730 as Reconstructed by Tree Rings,
W84-03145 2E

POWERPLANTS
Operational Flood Routing for Hydroelectric Plants,
W84-02993 4A

Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

PRAWN
The Influences of Temperature Variations and Thermal Pollution on Various Aspects of the Biology of the Prawn Palaemon Pacificus (Stimpson),
W84-03371 5C

PRECIPITATION
Precipitation over Northern Italy: A Description by Means of Principal Component Analysis,
W84-03146 2B

Relationships Between Chloride and Major Cations in Precipitation and Streamwaters in the Windermere Catchment (English Lake District),
W84-03297 5B

Supercooled Liquid Water and Ice Crystal Distributions Within Sierra Nevada Winter Storms,
W84-03303 2B

Semi-Quantitative Precipitation Forecasts for Gomti Catchment by Synoptic Analogue Method,
W84-03309 2B

Basin Precipitation Estimates by Bethlahmy's Two-Axis Method,
W84-03341 2B

A Stochastic Model for a Small-Time-Interval-Intermittent Hydrologic Process,
W84-03346 2B

Recent Developments on the Probable Maximum Precipitation (PMP) Estimation in China,
W84-03347 2B

Throughfall pH: Effect of Precipitation Timing and Amount,
W84-03401 5B

Chemical Optimization of Tertiary Contact Filters,
W84-03479 5D

Distribution of Mean Annual Precipitation Across Some Steepland Regions of New Zealand,
W84-03481 2B

Variations of the Stocking (Te Wae Wae) Glacier, Mount Cook, and Climatic Relationships,
W84-03484 2C

PREDICTION
Predicting Algal Stimulatory Properties of Wastewater,
W84-03089 5C

Short-Term Climate Predictions for Water Management,
W84-03156 4A

An Attempt to Pre-Determine Low Water Flows in Streams Losing Water in Calcareous Regions: Example of the Tille River Between Til-Chatel and Spoy (21) (Essai de Predetermination des Debits d'Etiage Sur les Cours d'Eau Presentant des Pertes en Region Calcaire. L'Exemple de la Tille Entre Til-Chatel et Spoy (21)),
W84-03362 2E

PRICING
Estimating Demand for Intake Water by Self-Supplied Firms,
W84-03406 6C

PRIMARY PRODUCTIVITY
Plankton Productivity and Biomass in a Tributary of the Upper Chesapeake Bay. I. Importance of Size-Fractionated Phytoplankton Productivity, Biomass and Species Composition in Carbon Export,
W84-03200 2L

Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

Primary Productivity Studies During Early Years of West Point Reservoir, Alabama-Georgia,
W84-03299 5C

Preliminary Measurements of Primary Production and Community Respiration in a Forest Stream in Hong Kong,
W84-03492 2H

PRINCE EDWARD ISLAND
Land Use Pressures on Coastal Estuaries in Atlantic Canada,
W84-03426 5B

PRINCIPAL COMPONENT ANALYSIS
Precipitation over Northern Italy: A Description by Means of Principal Component Analysis,
W84-03146 2B

PROBABILISTIC PROCESS
CRUE: A Model for Calculation the Probability of River Flooding (CRUE: Un Modele d'Estimation des Probabilites des Debits de Crue),
W84-03359 2E

PROBABILITY
Probability Sampling Techniques for Estimating Soil Erosion,
W84-03184 2J

Probability of Waterlogging Estimated from Historical Rainfall Records,
W84-03446 2G

PRODUCTION
The Ecology of Lake Nakuru (Kenya); V. Production and Consumption of Consumer Organisms,
W84-03150 2H

PUBLIC HEALTH
Studies on Bacteriological Quality of Nainital Lake Water in Different Seasons,
W84-02989 5B

PUBLIC OPINION
Private Enforcement of Federal Antipollution Laws Through Citizen Suits: A Model,
W84-03002 6F

PUBLIC TRUST DOCTRINE
Wherever the Water Flows: Lyon Applies the Public Trust to Non-Tidal Water,
W84-03004 6E

PUERTO RICO
Equitable Discretion Under the Federal Water Pollution Control Act: Weinberger v. Romero-Barcelo,
W84-03005 6E

PUMPING TESTS
Determination of Horizontal Aquifer Anisotropy with Three Wells,
W84-03080 2F

QUALITATIVE ANALYSIS
Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

QUANTITATIVE ANALYSIS
Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

RADIOCHEMICAL ANALYSIS
Radiochemical Techniques Applied to Laboratory Studies of Water Leaching of Heavy Metals from Coal Fly Ash,
W84-03374 5B

RAIN
Effect of Rain on Surface Reaeration,
W84-03468 2K

RAINBOW TROUT
The Distribution and Accumulation of Aluminum in Rainbow Trout Following a Whole-Lake Alum Treatment,
W84-02963 5B

Sublethal Effects of Treated Liquid Effluent From a Petroleum Refinery. III. Avoidance and Other Locomotor Responses of Rainbow Trout,
W84-03122 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. IV. Respiratory Movements and Coughing of Rainbow Trout,
W84-03123 5C

RAINBOW TROUT CELLS
Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium,
W84-03114 5C

RAINFALL
Freshwater Impacts in Normally Hypersaline Marshes,
W84-03036 2L

Rainfall Analysis by Power Transformation,
W84-03044 2B

A Model for Estimating One-Minute Rainfall Rates,
W84-03045 2A

The Utilization of Nimbus-7 SMMR Measurements to Delineate Rainfall over Land,
W84-03147 2B

The Derivation and Validation of a New Model for the Interception of Rainfall by Forests,
W84-03205 2I

Simulation of a Rainfall Record for the Site of a New Agricultural Development: An Example from Northern Syria,
W84-03211 2B

A Comparative Study of the Ionic Composition of Rainwater and Atmospheric Aerosols: Implications for the Mechanism of Acidification of Rainwater,
W84-03287 2K

A Theoretical Study Regarding Heterogeneity of Rainfall over Madhya Maharastra,
W84-03305 2B

Interpolation of Short Duration Rainfall from 24-Hour Rainfall in Lower Godavari Basin,
W84-03307 2B

Automated Rain Sampler for Trace Organic Substances,
W84-03330 5A

The Meteorological Office Rainfall and Evaporation Calculation System - MORECS,
W84-03442 2B

Probability of Waterlogging Estimated from Historical Rainfall Records,
W84-03446 2G

Infrared Remote Sensing for Monitoring Rainfall,
W84-03455 2B

Analytical Solutions of Kinematic Equations for Erosion on a Plane. II. Rainfall of Finite Duration,
W84-03462 2J

Hydrology of a Basin with Extreme Rainfalls-Cropp River, New Zealand,
W84-03482 2E

RAINFALL DISTRIBUTION
The Sub-Divisional Rainfall Distribution Across the Western Ghats During the Southwest Monsoon Season,
W84-03306 2B

Physically Meaningful Parameters that Characterise Rainfall Totals and Rainfall Extremes,
W84-03487 2B

RAINFALL INDEX
Rainfall Erosion Indices for Canada East of the Rocky Mountains,
W84-03225 2J

RAINFALL-RUNOFF RELATIONSHIPS
Runoff Fraction and Pollution Levels in Runoff from a Waste Rock Dump Undergoing Pyritic Oxidation,
W84-02987 5B

Field Verification of Runoff Curve Numbers for Fallow Rotations,
W84-03070 2E

Rainfall-Runoff Relationships of Some Catchments with Karstic Geomorphology under Arid to Semi-Arid Conditions,
W84-03338 2A

Identification and Prediction of Nonlinear Hydrologic Systems by the Filter-Separation Autoregressive (AR) Method: Extension to Hourly Hydrologic Data,
W84-03343 2A

Identification of a Volterra Series Conceptual Model Based on a Cascade of Nonlinear Reservoirs,
W84-03345 2A

Meixner Functions for Derivation of the Unit Hydrograph,
W84-03466 2A

REASONABLE USE
Toward a Unified Reasonable Use Approach to Water Drainage in Washington,
W84-03014 6E

RECHARGE
The Variability of Recharge of the English Chalk Aquifer,
W84-03439 2F

RECREATION
A Time Series Approach to Forecasting Angling Activity at a Recreational Site Based on Past Successes,
W84-03024 6B

REFLECTANCE
Yield, Water Relations, Gas Exchange, and Surface Reflectances of Near-Isogenic Wheat Lines Differing in Glaucousness,
W84-03277 2I

REGULATIONS
Anticipate Future Requirements for Wastewater Handling Systems,
W84-02984 5D

Assessing Land-Use Regulations in Coastal Wetlands: The Case of the Long Point Area, Lake Erie, Ontario,
W84-03425 6F

RELIABILITY
Urban Design-Storm Sensitivity and Reliability
W84-03336 4A

REMOTE SENSING
Quantitative Expression of Soil-Moisture Func tion for Remote Indication,
W84-03028 2C

Remote Sensing and Geophysical Investigation of Glacial Buried Valleys in Northeaster Kansas,
W84-03079 2I

Estimation of Evapotranspiration at One Time of-Day Using Remotely Sensed Surface Tem peratures,
W84-03453 2I

Estimation of Daily Evapotranspiration fron One Time-of-Day Measurements,
W84-03454 2I

Infrared Remote Sensing for Monitoring Rain fall,
W84-03455 2I

RESEARCH
Research on Watershed Hydrology at the Uni versity of Illinois,
W84-03333 2A

RESERVOIRS
The Behaviour of Silt-Laden Current,
W84-02994 2

Reservoir Circulation Patterns and Water Qual ity,
W84-03094 2H

Biology of the Arctic Grayling, Thymallus arcti cus (Thymallidae), in Ust' - Ilim Reservoir,
W84-03103 6C

Role of Current on the Distribution of Juvenil Fishes in Reservoirs,
W84-03104 2H

Oogenesis of the Rybinsk Reservoir Bream Abramis brama (Cyprinidae),
W84-03105 2H

Toxicity of Cyanobacteria in Dutch Lakes and Reservoirs,
W84-03117 2H

Evaluating the Safety and Seismic Stability o Embankment Reservoirs,
W84-03139 8A

Keeping Old Reservoirs Active,
W84-03140 8A

Diatoms in Fountains, Reservoirs and Som Other Humid and Dry Localities in Rome, Italy
W84-03311 2H

Stochastic Nature of Outputs from Conceptua Reservoir Model Cascades,
W84-03342 2A

Identification of a Volterra Series Conceptua Model Based on a Cascade of Nonlinear Reser voirs,
W84-03345 2A

A Binary State DP Algorithm for Operatio Problems of Multireservoir Systems,
W84-03407 6A

RESIDUE MANAGEMENT
Residue Management and Cultural Practices fo a Semiarid Region,
W84-03063 3I

RESPIRATION
Preliminary Measurements of Primary Production and Community Respiration in a Forest Stream in Hong Kong,
W84-03492 2H

REVIEWS
The Northwest's Hydroelectric Heritage: Prologue to the Pacific Northwest Electric Power Planning and Conservation Act,
W84-03030 6G

RHINE RIVER
Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

Research in Environmental Pollution; I. Determination of Polychlorinated Styrenes (PCS's) in Rhine Fish,
W84-03189 5A

RHODAMINE DYE
Rhodamine WT Dye Losses in a Mountain Stream Environment,
W84-03399 5A

RICHTER LAKE
Stratification and Mixing in Lakes of Taylor County, Wisconsin, with Emphasis on Richter Lake,
W84-03491 2H

RIMOUSKI RIVER
Chemistry of Dissolved and Particulate Material in the Estuary of the Rimouski River (Contribution a L'Etude Chimique du Materiel Dissous et Particulaire de L'Estuaire de la Riviere Rimouski),
W84-03108 2L

RISKS
Integrated Risk and Uncertainty Assessment in Water Resources Within a Multiobjective Framework,
W84-03352 6A

RIVER BASINS
Missouri River - The New Compacting Game,
W84-03396 6B

A Dynamic Model of Basin Sediment Yield,
W84-03415 2J

Hydrology of a Basin with Extreme Rainfalls-Cropp River, New Zealand,
W84-03482 2E

RIVER CONTINUUM CONCEPT
Relationships among Chemical, Physical, and Biological Indices along River Continua Based on Multivariate Analyses,
W84-03494 2H

RIVER FLOW
River Flow Reconstructions and Their Use, Part 1,
W84-03423 2E

Regional Variability of Soil Characteristics for Flood and Low Flow Estimation,
W84-03440 2E

Reliability of River-Treatment Plant Systems,
W84-03474 5C

RIVERINE PLAIN
Water Balance of Three Irrigated Crops on Fine-Textured Soils of the Riverine Plain,
W84-03238 2I

RIVERS
Fluoride Pollution in French Rivers and Estuaries,
W84-03202 2L

Life History and Ecology of the Humpback Chub in the Little Colorado and Colorado Rivers of the Grand Canyon,
W84-03313 2H

Reproduction by the Endangered Cui-ui in the Lower Truckee River,
W84-03321 2H

Allochthonous Drift from Backwaters to the Main Channel of the Mississippi River,
W84-03323 2E

Sources and Transport of Hydrocarbons in the Green-Duwamish River, Washington,
W84-03327 5B

RIVERWATER
Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

ROACH
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

ROADCUTS
Tracing Subsurface Flow on Roadcuts on Steep, Forested Slopes,
W84-03177 2G

ROCK PROPERTIES
Erosional Unloading and Fluid Pressures in Hydraulically 'Tight' Rocks,
W84-03236 8E

Mine Drainage and Rock Type Influences on Eastern Ohio Stream Water Quality,
W84-03391 5B

A Stochastic Model of a Fractured Rock Conditioned by Measured Information,
W84-03414 8E

ROCKY MOUNTAIN NATIONAL PARK
Comparative Water Chemistry of Four Lakes in Rocky Mountain National Park,
W84-03393 2H

ROME
Diatoms in Fountains, Reservoirs and Some Other Humid and Dry Localities in Rome, Italy,
W84-03311 2H

ROOT DISTRIBUTION
Root Distribution and Water Use Efficiency of Alfalfa as Influenced by Depth of Irrigation,
W84-03241 2I

ROOTS
Effect of Soil Texture on Critical Bulk Densities for Root Growth,
W84-03182 2G

Root System Characteristics of Two Soybean Isolines Undergoing Water Stress Conditions,
W84-03274 2I

RUFFE
Distribution of Fish and Food of Roach Rutilus rutilus, Bleak Alburnus alburnus Bream Abrumis brama and Ruffe Acerina cernua in Lake Vansjo, South-East Norway (Fordeling av Fisk, Samt Ernaering hos Mort, Laue, Brasme og Hork i Vansjo, Ostfold),
W84-03138 2H

RUNNING WATERS
Uptake, Translocation and Release of Carbon by Submersed Macrophytes from Running Water Habitats (Aufnahme, Transport und Abgabe von Kohlenstoff durch Submerse Makrophyten von Fliesswasserstandorten,
W84-03175 2H

RUNOFF
Soil and Nutrient Runoff Losses with In-Row, Chisel-Planted Soybeans,
W84-03062 2J

Field Verification of Runoff Curve Numbers for Fallow Rotations,
W84-03070 2E

Relationship of Runoff and Soil Loss to Ground Cover of Native and Reclaimed Grazing Land,
W84-03256 2E

The Kernel Function for Watershed Runoff Modeling,
W84-03335 2E

Runoff Models in a Small Urban Watershed: First Results of an Experimental Study (Modele de Crue Dans un Petit Bassin Urbain: Premiers Resultats d'Une Recherche Experimentale),
W84-03363 2E

S'GRAVENDEL NATURE RESERVE
The Nature Reserve s'Gravendel (Retie, Belgium); I. Phytosociological Description in Relation to Moisture and Soil Conditions (Het Natuurgebied 's-Gravendel (Retie, Belgie); I. Fitosociologische Beschrijving in Relatie tot Vochtigheid en Bodem),
W84-03128 2L

SABINE PASS
Observation of Episodic Sedimentation in a Tidal Inlet (Sabine Pass, Texas and Louisiana),
W84-03107 2L

SAFETY
Evaluating the Safety and Seismic Stability of Embankment Reservoirs,
W84-03139 8A

SAGINAW BAY
Retrospective Analysis of the Response of Saginaw Bay, Lake Huron, to Reductions in Phosphorus Loadings,
W84-03033 5C

SALINE WATER
Fertilizer and Salty Water Effects on Phaseolus,
W84-03239 3C

Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

SALINITY
Transient Hydrodynamic and Salinity Simulations in the Chesapeake Bay Network,
W84-03037 2L

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Relationship of Irrigation Water Salinity and Soil Water Salinity,
W84-03221 2G

Irrigation Scheduling under Saline High Water Tables,
W84-03222 3F

Leaching Requirement for Salinity Control III. Barley, Cowpea, and Celery,
W84-03431 3C

Thermohaline Convection in Flowing Groundwater,
W84-03465 2F

SALMON
Fishing Rights: Indian Fishing Rights and Congress: the Salmon and Steelhead Conservation and Enhancement Act of 1980,
W84-02975 6E

Influence of Deteriorating Water Quality on Growth and Development of Chum Salmon (Oncorhynchus keta) Larvae in a Japanese-Style Keeper Channel,
W84-03020 5C

SALT MARSHES
Freshwater Impacts in Normally Hypersaline Marshes,
W84-03036 2L

Nitrogen Losses from a Louisiana Gulf Coast Salt Marsh,
W84-03199 2L

SALVINIA
Growth of Salvinia molesta as Affected by Water Temperature and Nutrition; II. Effects of Phosphorus Level,
W84-03192 5C

A Study on the Growth of Salvinia molesta Mitchell in Relation to Light and Temperature,
W84-03194 5C

SAMPLING
Evaluation of Sampling Methods for the Determination of Trace Organics in Water,
W84-03163 5A

Probability Sampling Techniques for Estimating Soil Erosion,
W84-03184 2J

Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

Sediment Sampling in Different Aquatic Environments: Statistical Aspects,
W84-03411 5A

SAND FILTERS
Lagoon Effluent Polishing With Intermittent Sand Filters,
W84-03096 5D

SANDHILL LAKES
Limnological Features of Some Northwestern Florida Lakes,
W84-02971 2H

SANDWORMS
Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

SANITATION
Providing Water Supplies and Sanitation for the Developing World,
W84-03101 6B

Rural Water-Supply and Sanitation Planning: The Use of Socioeconomic Preconditions in Project Identification,
W84-03355 6A

SARGASSUM
Metals in the Pacific Sargassum Algae as Related to Water Pollution Monitoring (Metally v Sostave Tikhookeanskikh Sargassovykh Vodoroslei v Svyazi s Problemoi Monitoringa Eagryaeneniya Vod),
W84-03312 5A

SATELLITE TECHNOLOGY
The Utilization of Nimbus-7 SMMR Measurements to Delineate Rainfall over Land,
W84-03147 2B

SCALLOPS
The Reproductive Cycle of the Bay Scallop, Argopecten irradians irradians (Lamarck), in a Small Coastal Embayment on Cape Cod, Massachusetts,
W84-03039 2L

SCANNING MULTICHANNEL MICROWAVE RADIOMETER
The Utilization of Nimbus-7 SMMR Measurements to Delineate Rainfall over Land,
W84-03147 2B

SCREENS
Evaporation from Screened Class A Pans in a Semi-Arid Climate,
W84-03207 2D

SEASONAL VARIATION
A Theoretical Study Regarding Heterogeneity of Rainfall over Madhya Maharastra,
W84-03305 2B

Seasonal Fluctuations in the Carbon Dioxide Partial Pressure in a Cave Atmosphere,
W84-03422 2A

SEAWATER
Nickel Toxicity to Estuarine/Marine Fungi and its Amelioration by Magnesium in Sea Water,
W84-02988 5C

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Direct Determination of Trace Amounts of Chlorophenols in Fresh Water, Waste Water and Sea Water,
W84-03160 5A

Sewage Sludge Coagulation and Settling in Seawater,
W84-03328 5B

SEDIMENT TRANSPORT
A Dynamic Model of Basin Sediment Yield,
W84-03415 2J

SEDIMENT YIELD
A Dynamic Model of Basin Sediment Yield,
W84-03415 2J

SEDIMENTATION
The Behaviour of Silt-Laden Current,
W84-02994 2J

Flocculent Settling in Quiescent Systems,
W84-03475 5D

SEDIMENTS
Potential Phytotoxicity of Diquat Accumulated by Aquatic Plants and Sediments,
W84-02990 5C

Fish/Sediment Concentration Ratios for Organic Compounds,
W84-03034 5C

Nonreversible Sorption of Phenolic Compounds by Sediment Fractions: The Role of Sediment Organic Matter,
W84-03035 5B

Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

The Geochemistry of Iron and Manganese in the Waters and Sediments of Bolstadfjord, S. W Norway,
W84-03135 2K

PCB and DDT Concentrations of Sediments from Swiss Shoreline of Lake Geneva, Switzerland, (Concentrations en PCB et DDT des Sediments Superficiels de la Rive Suissec du Lac Leman),
W84-03173 5B

Bonding Forms of Heavy Metals in Sediments and Sludges: Sorption/Mobilization, Chemical Extraction and Bioavailability (Bindungsformen von Schwermetallen in Sedimenten und Schlammen: Sorption/Mobilisierung, chemische Extraktion und Bioverfugbarkeit),
W84-03188 5B

Sediment Sampling in Different Aquatic Environments: Statistical Aspects,
W84-03411 5A

The Geochemical Record of Major Cations and Trace Metals in a Productive Lake; Analysis of Thinly Sliced Sediment Samples Characterised by Diatom Stratigraphy,
W84-03500 2H

SEEDLINGS
A Method For Inducing Controlled Moisture Stress on Seedlings,
W84-03267 2

SEEPAGE
Seepage from Lake Burullus into the Reclaimed Mansour and Zawia Polder Area,
W84-03456 2F

SEINE RIVER
A Model of the Dispersion of Soluble of Pseudo Soluble Substances in Waterways. Application to the case of the Seine Upstream of Paris (Modelisation de la Dispersion des Substances Solubles ou Pseudo-Solubles dans un Cours d. Eau Application au Cas de la Seine a l'Amont de Paris),
W84-03358 5A

SELECTIVE WITHDRAWAL
Multilevel Withdrawal and Water Quality,
W84-03472 2H

SEMIARID LANDS
Residue Management and Cultural Practices for a Semiarid Region,
W84-03063 3F

Soil Management for Semiarid Regions,
W84-03450 3F

SENESCENCE
Significance of Accelerated Leaf Senescence a Low Water Potentials for Water Loss and Grain Yield in Maize,
W84-03285 2

SENSITIVITY
Urban Design-Storm Sensitivity and Reliability
W84-03336 4A

SETTLING
Sewage Sludge Coagulation and Settling in Seawater,
W84-03328 5B

SETTLING RATES
Flocculent Settling in Quiescent Systems,
W84-03475 5D

SHALLOW LAKES
Thermal Conditions of Bottom Sediments in Five Shallow Lakes of Masurian Lakeland,
W84-03134 2H

SHORES
Wherever the Water Flows: Lyon Applies the Public Trust to Non-Tidal Water,
W84-03004 6E

SHORT-TERM PLANNING
Short-Term Climate Predictions for Water Management,
W84-03156 4A

SHRIMP
Accumulation of PCBs, Mercury and Cadmium by Nereis virens, Mercenaria mercenaria and Palaemonetes pugio from Contaminated Harbor Sediments,
W84-03112 5B

SILICA
Relationships Between Ground-water Silica, Total Dissolved Solids, and Specific Electrical Conductivity,
W84-03082 5A

SILT
Model of Adaptation of Active-Silt Ecosystem to Multicomponent Pollution,
W84-03026 2J

SIMULATION
On the Application of the Boundary Layer Approximation for the Simulation of Density Stratified Flows in Aquifers,
W84-03463 2F

SIRATRO
Nitrogen Fixing Activity of Water Stressed Siratro,
W84-03259 2I

SLASH BURNING
Effects of Clearcutting and Slash Burning on Streamwater Chemistry and Watershed Nutrient Budgets in Southwestern British Columbia,
W84-03410 5B

SLOPES
Soil Erosion on Subarctic Forest Slopes,
W84-03056 2J

SLUDGE
Bonding Forms of Heavy Metals in Sediments and Sludges: Sorption/Mobilization, Chemical Extraction and Bioavailability (Bindungsformen von Schwermetallen in Sedimenten und Schlammen: Sorption/Mobilisierung, chemische Extraktion und Bioverfugbarkeit),
W84-03188 5B

SLUDGE COAGULATION
Sewage Sludge Coagulation and Settling in Seawater,
W84-03328 5B

SLUDGE DISPOSAL
Sludge Treatment by Oxyozosynthesis Stops Ocean Dumping,
W84-03190 5D

SLUDGE TREATMENT
Sludge Treatment by Oxyozosynthesis Stops Ocean Dumping,
W84-03190 5D

SNAGGING
Environmental Aspects of Clearing and Snagging,
W84-03473 6G

SNAILS
A Comparative Survey of Ancylus fluviatilis (Muller) Populations in the Afon Crafnant, N. Wales, Above and Below an Input of Zinc from Mine-Waste,
W84-03490 5C

SNOWMELT
Comments Concerning 'Convection Patterns in a Pond',
W84-02981 2C

SNOWPACK
Acid Snowpack Chemistry in Pennsylvania, 1979-81,
W84-03405 5B

SODIUM
Chemical Composition of Water-Bodies in the English Lake District: Relationships Between Chloride and Other Major Ions Related to Solid Geology, and a Tentative Budget for Windermere,
W84-03293 2K

SOIL
Effects of Irrigation on Accumulation of Soil and Symbiotically Fixed N by Soybean Grown on a Norfolk Loamy Sand,
W84-03260 2I

SOIL AERATION
Perennial Ryegrass Growth, Water Use, and Soil Aeration Status under Soil Compaction,
W84-03240 2I

SOIL CHEMISTRY
Effect of Soluble Species Released from Soil Sources on the Composition of Soil and Drainage Solutions,
W84-03180 5B

SOIL COLOR
Color Patterns and Water Table Levels in Some Indiana Soils,
W84-03181 2G

SOIL COMPACTION
Perennial Ryegrass Growth, Water Use, and Soil Aeration Status under Soil Compaction,
W84-03240 2I

Turfgrass Growth, N Use, and Water Use under Soil Compaction and N Fertilization,
W84-03250 2I

SOIL CONSERVATION
What is Conservation Tillage,
W84-03058 4D

Conservation Tillage for Erosion Control,
W84-03059 4D

Long-Term Annual Runoff and Soil Loss from Conventional and Conservation Tillage of Corn,
W84-03064 4D

Soil Conservation Strategies in the Third World,
W84-03068 4D

Runoff Curve Numbers for Conservation Tillage,
W84-03069 4D

SOIL DENSITY
Effect of Soil Texture on Critical Bulk Densities for Root Growth,
W84-03182 2G

SOIL EROSION
Soil Erosion on Subarctic Forest Slopes,
W84-03056 2J

Soil and Nutrient Runoff Losses with In-Row, Chisel-Planted Soybeans,
W84-03062 2J

Soil Erosion from Five Soybean Tillage Systems,
W84-03066 2J

Probability Sampling Techniques for Estimating Soil Erosion,
W84-03184 2J

Soil Erosion and Productivity, A Rational Look at a Complex Situation,
W84-03231 2J

Relationship of Runoff and Soil Loss to Ground Cover of Native and Reclaimed Grazing Land,
W84-03256 2E

SOIL MANAGEMENT
Soil Management for Semiarid Regions,
W84-03450 3F

SOIL MOISTURE
Direct Evaporation from Soil Under a Row Crop Canopy,
W84-03204 2D

An Evaluation of the Success of Morecs, a Meteorological Model, in Estimating Soil Moisture Deficits,
W84-03212 2G

SOIL MOISTURE DEFICIT
Alfalfa Response to Soil Water Deficits. II. Plant Water Potential, Leaf Conductance, and Canopy Temperature Relationships,
W84-03282 2D

Alfalfa Response to Soil Water Deficits. III. Nodulation and N2 Fixation,
W84-03283 2I

SOIL MORPHOLOGY
Soil Morphology and Water Regimes in 3 Recent Alluvial Soils on the Taieri Plains, South Island, New Zealand,
W84-03485 2G

SOIL PROPERTIES
Water Retention Equations and Their Relationship to Soil Organic Matter and Particle Size Distribution for Disturbed Samples,
W84-03226 2G

The Role of Soil in Determining Surface Water Composition,
W84-03384 2K

Use of Soil Survey Data to Select Measurement Techniques for Hydraulic Conductivity,
W84-03437 2G

Regional Field Study of the Spatial Variability of Selected Soil Physical Properties,
W84-03441 2G

SOIL SALINITY
Irrigation Scheduling under Saline High Water Tables,
W84-03222 3F

SOIL TEXTURE
Water Balance of Three Irrigated Crops on Fine-Textured Soils of the Riverine Plain,
W84-03238 2I

SOIL TYPES
Color Patterns and Water Table Levels in Some Indiana Soils,
W84-03181 2G

SOIL WATER
Quantitative Expression of Soil-Moisture Function for Remote Indication,
W84-03028 2G

The Nature Reserve s'Gravendel (Retie, Belgium); I. Phytosociological Description in Relation to Moisture and Soil Conditions (Het Natuurgebied 's-Gravendel (Retie, Belgie); I. Fitosociologische Beschrijving in Relatie tot Vochtigheid en Bodem),
W84-03128 2L

A Transient Method for Measuring Soil Water Diffusivity and Unsaturated Hydraulic Conductivity,
W84-03178 2G

Effect of Soil Texture on Critical Bulk Densities for Root Growth,
W84-03182 2G

Irrigation Decisions Simplified with Electronics and Soil Water Sensors,
W84-03183 2G

Soil Water Flux in Humid Tropical Latosols Under Coconut (Cocos nucifera Linn.),
W84-03216 2G

Relationship of Irrigation Water Salinity and Soil Water Salinity,
W84-03221 2G

Irrigation Scheduling under Saline High Water Tables,
W84-03222 3F

Intermittent Infiltration and Evaporation from Soil Columns,
W84-03227 2G

Soil Water Desorption Curves Estimated from Limited Data,
W84-03229 2G

Soil Water and Population Influence on Hybrid Sunflower Yield and Uniformity of Stand,
W84-03261 2I

Alfalfa Response to Soil Water Deficits. I. Growth, Forage Quality, Yield, Water Use, and Water-Use Efficiency,
W84-03281 2I

Numerical Analysis of Soil Water Movement under Conditions of Rapid Intermittency of Water Application,
W84-03418 2G

Effect of Mixed Cation Solutions on Hydraulic Soil Properties,
W84-03432 2G

Analyzing Field-Measured Soil-Water Properties,
W84-03436 2G

A Heuristic Model of Soil Water Regimes in Clay Soils in the Presence of Mole Drainage,
W84-03438 2G

Water Use by Alfalfa, Maize, and Barley as Influenced by Available Soil Water,
W84-03444 2I

Wheat Root Growth, Grain Yield and Water Uptake as Influenced by Soil Water Regime and Depth of Nitrogen Placement in a Loamy Sand Soil,
W84-03445 2I

Transport of Water in Frozen Soil. II. Effects of Ice on the Transport of Water Under Isothermal Conditions,
W84-03458 2G

The Soil-Moisture Zone in a Physically-Based Hydrologic Model,
W84-03459 2G

Soil Morphology and Water Regimes in 3 Recent Alluvial Soils on the Taieri Plains, South Island, New Zealand,
W84-03485 2G

SOIL WATER POTENTIAL

Simulating the Effects of Weather Variables and Soil Water Potential on a Corn Canopy Temperature,
W84-03210 3F

SOLAR RADIATION

A Study on the Growth of Salvinia molesta Mitchell in Relation to Light and Temperature,
W84-03194 5C

SOLUBILITY

A Model of the Dispersion of Soluble of Pseudo-Soluble Substances in Waterways. Application to the case of the Seine Upstream of Paris (Modelisation de la Dispersion des Substances Solubles ou Pseudo-Solubles dans un Cours d. Eau. Application au Cas de la Seine a l'Amont de Paris),
W84-03358 5A

SOUTH ISLAND

Soil Morphology and Water Regimes in 3 Recent Alluvial Soils on the Taieri Plains, South Island, New Zealand,
W84-03485 2G

SOUTH WALES

The Macroinvertebrate Fauna of the Drainage Channels of the Gwent Levels, South Wales,
W84-03289 5C

SOYBEAN

Field Evaluation of a Water Relations Model for Soybean. I. Validity of Some Basis Assumptions,
W84-03245 2I

Effects of Irrigation on Accumulation of Soil and Symbiotically Fixed N by Soybean Grown on a Norfolk Loamy Sand,
W84-03260 2I

SOYBEAN YIELD

Effects of Wastewater Irrigation and Plant and Row Spacing on Soybean Yield and Development,
W84-03271 3C

Moisture Stress and N Redistribution in Soybean,
W84-03275 2I

Irrigation of Soybean Genotypes During Reproductive Ontogeny II. Yield Component Responses,
W84-03280 2I

SOYBEANS

Soil and Nutrient Runoff Losses with In-Row, Chisel-Planted Soybeans,
W84-03062 2J

Soil Erosion from Five Soybean Tillage Systems,
W84-03066 2J

Response of Soybean Cultivars to Irrigation of a Clay Soil,
W84-03268 3F

Soybean Water Status and Canopy Microclimate Relationships at Four Row Spacings,
W84-03273 2I

Root System Characteristics of Two Soybean Isolines Undergoing Water Stress Conditions,
W84-03274 2I

Irrigation of Soybean Genotypes During Reproductive Ontogeny. I. Agronomic Responses,
W84-03279 2I

SPATIAL DISTRIBUTION

Regional Field Study of the Spatial Variability of Selected Soil Physical Properties,
W84-03441 2G

SPATIAL HETEROGENEITY

Spatial Heterogeneity and Models of Surface Runoff,
W84-03334 2E

SPECIES DIVERSITY

Distribution and Abundance of Zooplankton in an Alkaline Freshwater Marsh in Northumberland County, Pennsylvania,
W84-02956 2L

The Desmids and Physical Characteristics of 100 Lakes in Northeastern Pennsylvania,
W84-02962 2H

SPECTRAL ANALYSIS

Spectral Measurements of Surface Suspended Matter in an Oxbow Lake in the Lower Mississippi Valley,
W84-02970 7B

SPILLS

Chemistry and Microbiology of a Sewage Spill in South San Francisco Bay,
W84-03038 5C

SPOT

Effects of Accumulated Dietary Kepone on Spot (Leiostomus xanthurus),
W84-03115 5C

SPRINKLER IRRIGATION

Wheat Development as Affected by Deficit, High Frequency Sprinkler Irrigation,
W84-03243 2I

Response of Dry Beans to Daily Deficit Sprinkler Irrigation,
W84-03262 3F

SPRUCE

Decline of Red Spruce in the Northern Appalachians: Assessing the Possible Role of Acid Deposition,
W84-03191 5C

ST. PETERSBURG

Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

STABILIZATION PONDS

Studies on Stabilization Ponds for Domestic Sewage in India,
W84-02957 5D

STATE JURISDICTION

Sporhase v. Nebraska ex rel. Douglas: Does the Dormant Commerce Clause Really Limit the Power of a State to Forbid (1) the Export of Water and (2) the Creation of a Water Right for Use in Another State,
W84-03013 6E

Water Supply: A State or Local Problem,
W84-03232 6F

STATES RIGHTS

So Its Not 'Ours' - Why Can't We Still Keep It A First Look at Sporhase v. Nebraska,
W84-03008 6E

Sporhase v. Nebraska ex rel. Douglas: State Control of Water Under the Constraints of the Commerce Clause,
W84-03010 6E

STATISTICAL ANALYSIS

Sediment Sampling in Different Aquatic Environments: Statistical Aspects,
W84-03411 5A

Nonparametric Tests for Trend in Water Quality,
W84-03419 5A

STATISTICAL METHODS

Analyzing Field-Measured Soil-Water Properties,
W84-03436 2G

STATISTICAL MODELS
Disaggregation Procedures for Generating Serially Correlated Flow Vectors,
W84-03412 2E

STEELHEAD
Fishing Rights: Indian Fishing Rights and Congress: the Salmon and Steelhead Conservation and Enhancement Act of 1980,
W84-02975 6E

STEM
Soil Water and Population Influence on Hybrid Sunflower Yield and Uniformity of Stand,
W84-03261 2I

STERILITY
Role of Panicle Exsertion in Water Stress Induced Sterility,
W84-03284 2I

STIGEOCLONIUM
Bioassays with Stigeoclonium Kutz. (Chlorophyceae) to Identify Nitrogen and Phosphorus Limitations,
W84-03193 5A

STIMPSON
The Influences of Temperature Variations and Thermal Pollution on Various Aspects of the Biology of the Prawn Palaemon Pacificus (Stimpson),
W84-03371 5C

STOCHASTIC MODELS
Analysis and Modeling of Palmer's Drought Index Series,
W84-03344 2B

A Stochastic Model for a Small-Time-Interval-Intermittent Hydrologic Process,
W84-03346 2B

STOCHASTIC PROCESS
A Stochastic Age-Structured Population Model of Striped Bass (Morone saxatilis) in the Potomac River,
W84-03023 2H

Stochastic Nature of Outputs from Conceptual Reservoir Model Cascades,
W84-03342 2A

A Stochastic Model of a Fractured Rock Conditioned by Measured Information,
W84-03414 8E

STOCKING GLACIER
Variations of the Stocking (Te Wae Wae) Glacier, Mount Cook, and Climatic Relationships,
W84-03484 2C

STORM SEEPAGE
Tracing Subsurface Flow on Roadcuts on Steep, Forested Slopes,
W84-03177 2G

STORM WATER
Oil and Grease in Urban Stormwaters,
W84-03470 5B

STRATIFICATION
Stratification and Mixing in Lakes of Taylor County, Wisconsin, with Emphasis on Richter Lake,
W84-03491 2H

STREAM BIOTA
Geothermal Effects on Stream Benthos: Separate Influences of Thermal and Chemical Components on Periphyton and Macroinvertebrates,
W84-03019 5C

STREAM CLASSIFICATION
Relationships among Chemical, Physical, and Biological Indices along River Continua Based on Multivariate Analyses,
W84-03494 2H

STREAM FLOW
Potomac River Streamflow Since 1730 as Reconstructed by Tree Rings,
W84-03145 2E

STREAM POLLUTION
Effects of Clearcutting and Slash Burning on Streamwater Chemistry and Watershed Nutrient Budgets in Southwestern British Columbia,
W84-03410 5B

STREAMFLOW
Low Flow Synthesis by Computer; Part One,
W84-02996 2E

Low Flow Synthesis by Computer; Part Two,
W84-02997 2E

An Attempt to Pre-Determine Low Water Flows in Streams Losing Water in Calcareous Regions: Example of the Tille River Between Til-Chatel and Spoy (21) (Essai de Predetermination des Debits d'Etiage Sur les Cours d'Eau Presentant des Pertes en Region Calcaire. L'Exemple de la Tille Entre Til-Chatel et Spoy (21)),
W84-03362 2E

STREAMS
The Distribution of Desmognathine Larvae (Amphibia: Plethodontidae) in Coal Surface Mine Impacted Streams of the Cumberland Plateau, USA,
W84-02961 2H

Alkalinity, Discharge, Average Velocity, and Invertebrate Drift Concentration in Subarctic Alaskan Streams,
W84-02969 2H

Microbial Heterotrophic Utilization of Dissolved Organic Matter in a Piedmont Stream,
W84-03295 5B

Relationships Between Chloride and Major Cations in Precipitation and Streamwaters in the Windermere Catchment (English Lake District),
W84-03297 5B

Community Structure in Some Southern English Streams: The Influence of Physicochemical Factors,
W84-03300 5C

Redd-Site Selection by Brook Trout and Brown Trout in Southwestern Ontario Streams,
W84-03320 2H

Mine Drainage and Rock Type Influences on Eastern Ohio Stream Water Quality,
W84-03391 5B

SUBARCTIC ZONE
Soil Erosion on Subarctic Forest Slopes,
W84-03056 2J

SUBLETHAL EFFECTS
Sublethal Effects of Treated Liquid Effluent From a Petroleum Refinery. III. Avoidance and Other Locomotor Responses of Rainbow Trout,
W84-03122 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. IV. Respiratory Movements and Coughing of Rainbow Trout,
W84-03123 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. V. Reproduction of Daphnia Pulex and Overall Evaluation,
W84-03124 5C

SUBMERGED PLANTS
Uptake, Translocation and Release of Carbon by Submersed Macrophytes from Running Water Habitats (Aufnahme, Transport und Abgabe von Kohlenstoff durch Submerse Makrophyten von Fliesswasserstandorten,
W84-03175 2H

SUBSOIL DRAINS
Functioning of Mole Drains in Clay Soil,
W84-03433 2G

SUBSURFACE IRRIGATION
An Electrical Analogue to Design Subirrigation Systems,
W84-03443 3F

SUCKERS
Temperature Preference and Avoidance by Adult Razorback Suckers,
W84-03315 5C

SULFUR
Sulphur and Chloride Deposition and Ecosystem Transport in a Strongly Acidified Lake Watershed,
W84-03388 5B

SUNFLOWER
Soil Water and Population Influence on Hybrid Sunflower Yield and Uniformity of Stand,
W84-03261 2I

SUPERCRITICAL FLOW
The Effects of Curvature in Supercritical Side Weir Flow,
W84-03165 8B

SUPPLEMENTAL IRRIGATION
Effect of Small Irrigation Amounts on the Yield of Wheat,
W84-03434 3F

SURFACE FLOW
A Numerical Procedure for Three-Dimensional Transient Free Surface Seepage,
W84-03467 2E

SURFACE MINING
Effects of Surface Mining on Aquatic Resources in North America,
W84-03197 5B

SURFACE RUNOFF
Spatial Heterogeneity and Models of Surface Runoff,
W84-03334 2E

SURFACE TEMPERATURE
Estimation of Evapotranspiration at One Time-of-Day Using Remotely Sensed Surface Temperatures,
W84-03453 2D

SURFACE WATER
Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream,
W84-03057 5B

Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

The Role of Soil in Determining Surface Water Composition,
W84-03384 2K

SUSPENDED SEDIMENTS
Spectral Measurements of Surface Suspended Matter in an Oxbow Lake in the Lower Mississippi Valley,
W84-02970 7B

SWEDEN
Properties of Acid Brown Water Streams in South Sweden,
W84-03502 5C

SWITZERLAND
Mixing Processes in Lakes: Mechanisms and Ecological Relevance,
W84-03167 2H

Chemical and Geochemical Studies of Lake Biel; II. A Chemical Approach to Lake Mixing,
W84-03168 2H

Hydrodynamics of the Lake of Geneva,
W84-03169 2H

Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich- und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle),
W84-03170 2H

PCB and DDT Concentrations of Sediments from Swiss Shoreline of Lake Geneva, Switzerland, (Concentrations en PCB et DDT des Sediments Superficiels de la Rive Suissec du Lac Leman),
W84-03173 5B

Possible Measures for the Restoration of Lake Sempach (Mogliche Massnahmen zur Restaurierung des Sempachersees),
W84-03174 5G

The Coregones of Lake Neuchatel: Fishery Yield; Age and Growth of Individuals Caught by Professional Fishermen (Les coregones du lac de Neuchatel: rendement de la peche; age et croissance des individus captures par les pecheurs professionnels),
W84-03176 5C

SYSTEMS ANALYSIS

Gravity Wastewater Collection Systems Optimization,
W84-03092 5B

TASMANIA

Macrobenthic Fauna of Great Lake, Arthurs Lake and Lake Sorell, Tasmania,
W84-03125 2H

Qualitative and Quantitative Variation in the Macrobenthic Fauna of the Original Lake and New Lake Areas of Great Lake and Arthurs Lake, Tasmania,
W84-03126 2H

Hydroelectric Development and Wilderness Conflict in South-West Tasmania,
W84-03324 6G

TEMPERATURE

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Evapotranspiration and Yield Estimation of Spring Wheat From Canopy Temperature,
W84-03264 2D

Effect of Wind on the Crop Water Stress Index Derived by Infrared Thermometry,
W84-03265 2I

Relationships Between Leaf Water Potential, Canopy Temperature, and Evapotranspiration in Irrigated and Nonirrigated Alfalfa,
W84-03270 2D

Alfalfa Response to Soil Water Deficits. II. Plant Water Potential, Leaf Conductance, and Canopy Temperature Relationships,
W84-03282 2D

Temperature Preference and Avoidance by Adult Razorback Suckers,
W84-03315 5C

Variations of the Stocking (Te Wae Wae) Glacier, Mount Cook, and Climatic Relationships,
W84-03484 2C

TEMPERATURE EFFECTS

Comments Concerning 'Convection Patterns in a Pond',
W84-02981 2C

Growth of Salvinia molesta as Affected by Water Temperature and Nutrition; II. Effects of Phosphorus Level,
W84-03192 5C

A Study on the Growth of Salvinia molesta Mitchell in Relation to Light and Temperature,
W84-03194 5C

The Influences of Temperature Variations and Thermal Pollution on Various Aspects of the Biology of the Prawn Palaemon Pacificus (Stimpson),
W84-03371 5C

TEMPORARY PONDS

The Natural History of a Nearctic Temporary Pond in Ontario with Remarks on Continental Variation in Such Habitats,
W84-02952 2H

TERTIARY WASTEWATER TREATMENT

The Third Wave in Water Quality Management,
W84-02980 6E

TETRACHLOROETHENE

Transformations of Tetrachloroethene and Trichloroethene in Microcosms and Groundwater,
W84-03367 5B

TEXAS

Focusing Mechanisms in the Texas Hill Country Flash Floods in 1978,
W84-03364 2B

THERMAL POLLUTION

Ecology of Planktonic Larvae of Dreissena polymorpha (Pall.) in Lakes with Different Degree of Heating,
W84-03152 5C

The Influences of Temperature Variations and Thermal Pollution on Various Aspects of the Biology of the Prawn Palaemon Pacificus (Stimpson),
W84-03371 5C

THERMAL SPRINGS

Geothermal Effects on Stream Benthos: Separate Influences of Thermal and Chemical Components on Periphyton and Macroinvertebrates,
W84-03019 5C

THERMAL STRATIFICATION

Thermal Conditions of Bottom Sediments in Five Shallow Lakes of Masurian Lakeland,
W84-03134 2H

THERMODYNAMICS

Thermal Impact of Residential Ground-Water Heat Pumps,
W84-03072 2F

THROUGHFALL

Throughfall pH: Effect of Precipitation Timing and Amount,
W84-03401 5B

TIDAL FLATS

Mangrove Distribution in Northwestern Australia in Relationship to Regional and Local Freshwater Seepage,
W84-02972 2L

TIDAL INLET

Observation of Episodic Sedimentation in a Tidal Inlet (Sabine Pass, Texas and Louisiana),
W84-03107 2L

TILLAGE

Long-Term Annual Runoff and Soil Loss from Conventional and Conservation Tillage of Corn,
W84-03064 4D

Soil Erosion from Five Soybean Tillage Systems,
W84-03066 2J

Tillage and Cultural Management of Irrigated Potatoes,
W84-03242 2G

TILLE RIVER

An Attempt to Pre-Determine Low Water Flows in Streams Losing Water in Calcareous Regions: Example of the Tille River Between Til-Chatel and Spoy (21) (Essai de Predetermination des Debits d'Etiage Sur les Cours d'Eau Presentant des Pertes en Region Calcaire. L'Exemple de la Tille Entre Til-Chatel et Spoy (21)),
W84-03362 2E

TIME SERIES ANALYSIS

A Time Series Approach to Forecasting Angling Activity at a Recreational Site Based on Past Successes,
W84-03024 6B

Use of Time-Series Analysis to Demonstrate Advection Rates of Different Variables in a Small Lake,
W84-03102 2H

TOTAL DISSOLVED SOLIDS

Concentrations of Total Dissolved Solids Preferred or Avoided by Endangered Colorado River Fishes,
W84-03314 5C

TOXAPHENE

Acute Effects of Toxaphene and Its Sediment-Degraded Products on Estuarine Fish,
W84-03021 5C

TOXICITY

Nickel Toxicity to Estuarine/Marine Fungi and its Amelioration by Magnesium in Sea Water,
W84-02988 5C

Delayed Toxicity of Carbofuran in Freshwater Teleosts, Channa punctatus (Bloch) and Anabas testudineus (Bloch),
W84-02992 5C

Acute Effects of Toxaphene and Its Sediment-Degraded Products on Estuarine Fish,
W84-03021 5C

Temperature, pH, Salinity, Hardness, and Particulates Mediate Nickel Toxicity to Eubacteria, an Actinomycete, and Yeasts in Lake, Simulated Estuarine, and Sea Waters,
W84-03111 5C

Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium,
W84-03114 5C

Toxicity of Cyanobacteria in Dutch Lakes and Reservoirs,
W84-03117 2H

Benthic Macroinvertebrates and Water Quality Assessment: Some Toxicological Considerations,
W84-03118 5C

The Microtox* as an Alternative Assay in the Acute Toxicity Assessment of Water Pollutants,
W84-03120 5C

Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

TRACE METALS
Trace Metals in the Gota River Estuary,
W84-03137 5B

The Geochemical Record of Major Cations and Trace Metals in a Productive Lake; Analysis of Thinly Sliced Sediment Samples Characterised by Diatom Stratigraphy,
W84-03500 2H

TRACERS
Possibilities and Limitations of Tracing Industrial Effluents in the Sea by Means of Capillary Chromatography,
W84-03158 5A

Rhodamine WT Dye Losses in a Mountain Stream Environment,
W84-03399 5A

TRANSFORMATION
Transformations of Tetrachloroethene and Trichloroethene in Microcosms and Groundwater,
W84-03367 5B

TRANSMISSIVITY
Kriged Estimates of Transmissivity in the Mesilla Bolson, New Mexico,
W84-03397 2F

TRANSPIRATION
Seasonal Estimates of Transpiration from a Millet Crop Using a Porometer,
W84-03214 2D

TREATED WATER
Sublethal Effects of Treated Liquid Effluent From a Petroleum Refinery. III. Avoidance and Other Locomotor Responses of Rainbow Trout,
W84-03122 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. IV. Respiratory Movements and Coughing of Rainbow Trout,
W84-03123 5C

Sublethal Effects of Treated Liquid Effluent from a Petroleum Refinery. V. Reproduction of Daphnia Pulex and Overall Evaluation,
W84-03124 5C

TREE RINGS
Potomac River Streamflow Since 1730 as Reconstructed by Tree Rings,
W84-03145 2E

TREES
Effects of Late-Growing-Season Inundation on Tree Species in the Central Plains,
W84-03055 2E

TREND
Nonparametric Tests for Trend in Water Quality,
W84-03419 5A

TRIAZINES
The Effect of Two Triazine Herbicides on the Productivity of Freshwater Marsh Periphyton,
W84-03119 5C

TRICHLOROETHENE
Transformations of Tetrachloroethene and Trichloroethene in Microcosms and Groundwater,
W84-03367 5B

TRIHALOMETHANES
Control of Trihalomethane Precursors in Drinking Water: Granular Activated Carbon With and Without Preozonation,
W84-03369 5F

TROPICAL REGIONS
Soil Water Flux in Humid Tropical Latosols Under Coconut (Cocos nucifera Linn.),
W84-03216 2G

TROUT
Trout-Zooplankton Relationships in Medical Lake, WA, Following Restoration by Aluminum Sulfate Treatment,
W84-02960 5G

Contaminant Accumulation and Physiological Response in Rainbow Trout (Salmo gairdneri) Reared on Naturally Contaminated Diets,
W84-03018 5C

Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

Acute Toxcity of Ammonia to Rainbow Trout,
W84-03318 5C

TURBIDITY
Turbidity Interferes with Accuracy in Heavy Metals Concentrations,
W84-03041 5B

TURBULENCE
Influence of Degree of Stream Turbulence on the Magnitude of the Critical Current Velocity for Fish,
W84-03027 8I

The Influence of Flow Turbulence on Fish Behavior,
W84-03106 2H

Turbulence Measurements in Stratified and Well-mixed Estuarine Flows,
W84-03203 2L

TURF GRASSES
Resistances to Evapotranspiration from a St. Augustinegrass Turf Canopy,
W84-03247 2D

TURFGRASS
Turfgrass Evapotranspiration. I. Factors Influencing Rate in Urban Environments,
W84-03266 2D

TURIBIDITY
Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

ULTRACLEAN SAMPLING
Application of Ultraclean Sampling and Analytical Techniques to an Investigation of the Impact of Power-Plant Derived Heavy Metals on Groundwater, Riverwater, Bottom Sediments and Benthic Organisms,
W84-03380 5A

UNDERGROUND WASTE DISPOSAL
Subsurface Injection of Treated Sewage into a Saline-Water Aquifer at St. Petersburg, Florida - Aquifer Pressure Buildup,
W84-03078 5D

UNIT HYDROGRAPHS
Meixner Functions for Derivation of the Unit Hydrograph,
W84-03466 2A

UNITED KINGDOM
U.K. Pushes R and D to Meet Potable Water Demand,
W84-03001 6D

UNSTEADY FLOW
Flood Routing Through a Flat, Complex Floodplain Using a One-Dimensional Unsteady Flow Computer Program,
W84-03395 8B

URBAN AREAS
Turfgrass Evapotranspiration. I. Factors Influencing Rate in Urban Environments,
W84-03266 2D

URBAN HYDROLOGY
Modelling of Hydrologic Processes in a Small Urbanized Hillslope Basin with Comments on the Effects of Urbanization,
W84-03337 2A

URBAN RUNOFF
Urban Design-Storm Sensitivity and Reliability,
W84-03336 4A

Modelling of Hydrologic Processes in a Small Urbanized Hillslope Basin with Comments on the Effects of Urbanization,
W84-03337 2A

URBAN WATERSHEDS
Runoff Models in a Small Urban Watershed: First Results of an Experimental Study (Modele de Crue Dans un Petit Bassin Urbain: Premiers Resultats d'Une Recherche Experimentale),
W84-03363 2E

URBANIZATION
Modelling of Hydrologic Processes in a Small Urbanized Hillslope Basin with Comments on the Effects of Urbanization,
W84-03337 2A

VAPOR BUDGET
Measurement of Evaporation by a Vapor Budget Technique,
W84-03421 2D

VARIABILITY
Overlap and Pollution-induced Variability in the Feeding Habits of Filefish (Pisces: Monacanthidae) from Apalachee Bay, Florida,
W84-03132 5C

VEGETATION
Gradient Analysis of the Vegetation of the Byron-Bergen Swamp, a Rich Fen in Western New York,
W84-02973 2L

A Discussion of the Relationships between the Principal Forms of the Combination Equation for Estimating Crop Evaporation,
W84-03217 2D

VEGETATION EFFECTS
Evaporation from the Irrigation Water, Foliage and Panicles of Paddy Rice in North-East Sri Lanka,
W84-03206 2D

VELOCITY
Finite-Element Methods Based on a Transport Velocity Representation for Groundwater Motion,
W84-03420 2F

VERDON RIVER
Hydrobiological Study of a Harnessed River: The Verdon (Etude Hydrobiologique d'une Riviere Amenagee: le Verdon Les Lacs de Barrage et les Troncons de Cours d'Eau a Debit Regule),
W84-03360 6G

VIRUSES
Enteric Viruses in New Zealand Wastewaters,
W84-03486 5A

VISTULA
Ecological Characteristics of Polisaprobic Section of the Vistula River below Warsaw,
W84-03154 5C

Oxygen Consumption and Survival of Asellus aquaticus L. (Crustacea) in Vistula River Section Highly Polluted by Municipal Sewage,
W84-03155 5C

VOLCANOES
Reduced Rates of Primary Production in the Columbia River Estuary following the Eruption of Mt. Saint Helens on 18 May 1980,
W84-03201 2L

VOLTAMMETRY
Investigations on Heavy Metal Speciation in Natural Waters by Voltammetric Procedures,
W84-03185 5B

WALES
A Comparative Survey of Ancylus fluviatilis (Muller) Populations in the Afon Crafnant, N. Wales, Above and Below an Input of Zinc from Mine-Waste,
W84-03490 5C

WALLEYE
Mortality of Walleye Eggs and Rainbow Trout Yolk-Sac Larvae in Low-pH Waters of the La-Cloche Mountain Area, Ontario,
W84-03316 2H

WASHINGTON
Trout-Zooplankton Relationships in Medical Lake, WA, Following Restoration by Aluminum Sulfate Treatment,
W84-02960 5G

Toward a Unified Reasonable Use Approach to Water Drainage in Washington,
W84-03014 6E

Lagrangian Meteorology and Measurements of Acidic Precipitation at Washington, D.C.,
W84-03286 5B

Engineering Economic Analyses of Artificial Recharge in the Columbia Basin Project, Washington,
W84-03402 4B

WASTE DISPOSAL
Water Pollution Arising from Solid Waste (Coal, Fly Ash, Slag) Disposal, and Measures to Prevent Water Pollution,
W84-03372 2B

Prevention of Water Pollution by the Use of Fly-Ash as a Substitute for Extracted Raw Materials,
W84-03379 5E

WASTE RECOVERY
Prevention of Water Pollution by the Use of Fly-Ash as a Substitute for Extracted Raw Materials,
W84-03379 5E

WASTEWATER
Chemistry and Microbiology of a Sewage Spill in South San Francisco Bay,
W84-03038 5C

Predicting Algal Stimulatory Properties of Wastewater,
W84-03089 5C

Enteric Viruses in New Zealand Wastewaters,
W84-03486 5A

WASTEWATER ANALYSIS
Occurrence of Low- and High-Chlorinated Phenols in Municipal Sewage Before and After Passing Through Biological Treatment Plants,
W84-03159 5D

Direct Determination of Trace Amounts of Chlorophenols in Fresh Water, Waste Water and Sea Water,
W84-03160 5A

Separation of Bacteria from a Methanogenic Wastewater Population by Utilizing a Self-Generating Percoll Gradient,

Hydrodynamic Studies of Lake Zurich and Lake Lugano; A Comparison Between Field Measurements and Results of Theoretical Models, (Stromungsdynamische Untersuchungen im Zurich-

und im Luganersee; Ein Vergleich von Feldmessungen mit Resultaten Theoretischer Modelle), W84-03170 2H

Numerical Models for the Currents Simulation of a Lake (Mathematische Modelle zur Simulation von Zirkulationsstromungen in Einem See), W84-03171 2H

WATER DEFICIT

Wheat Development as Affected by Deficit, High Frequency Sprinkler Irrigation, W84-03243 2I

Response of Dry Beans to Daily Deficit Sprinkler Irrigation, W84-03262 3F

WATER DEMAND

U.K. Pushes R and D to Meet Potable Water Demand, W84-03001 6D

Estimating Demand for Intake Water by Self-Supplied Firms, W84-03406 6C

WATER EXPORT

Constitutional Law - Water Law - Constitutionality of Water Export Bans and Limitations on Interstate Water Allocation. Sporhase v. Nebraska ex rel. Douglas, - U.S. -, 102 S. Ct. 3456 (1982), W84-03011 6E

Sporhase v. Nebraska ex rel. Douglas: Does the Dormant Commerce Clause Really Limit the Power of a State to Forbid (1) the Export of Water and (2) the Creation of a Water Right for Use in Another State, W84-03013 6E

WATER LAW

The Third Wave in Water Quality Management, W84-02980 6E

WATER LEVEL FLUCTUATIONS

Ground-Water Mounding Beneath a Large Leaching Bed, W84-03083 4B

WATER LOSS

Significance of Accelerated Leaf Senescence at Low Water Potentials for Water Loss and Grain Yield in Maize, W84-03285 2I

WATER MANAGEMENT

Short-Term Climate Predictions for Water Management, W84-03156 4A

Principles of Water Management Under Drought Conditions, W84-03451 3F

WATER POLLUTION

Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands, W84-03116 5C

WATER POLLUTION CONTROL

The 'Decade of the Environment' in the U.S.S.R., W84-02986 6G

Private Enforcement of Federal Antipollution Laws Through Citizen Suits: A Model, W84-03002 6F

Equitable Discretion Under the Federal Water Pollution Control Act: Weinberger v. Romero-Barcelo, W84-03005 6E

Managing Agricultural Pollution, W84-03006 6E

WATER POLLUTION CONTROL ACT

Equitable Discretion Under the Federal Water Pollution Control Act: Weinberger v. Romero-Barcelo, W84-03005 6E

WATER POLLUTION EFFECTS

An Index of Community Structure Sensitive to Water Pollution, W84-02966 5C

Lake Ontario's Fish - How They Almost Got Away, W84-02985 5C

Influence of Deteriorating Water Quality on Growth and Development of Chum Salmon (Oncorhynchus keta) Larvae in a Japanese-Style Keeper Channel, W84-03020 5C

Chemistry and Microbiology of a Sewage Spill in South San Francisco Bay, W84-03038 5C

Overlap and Pollution-induced Variability in the Feeding Habits of Filefish (Pisces: Monacanthidae) from Apalachee Bay, Florida, W84-03132 5C

Ecological Characteristics of Polisaprobic Section of the Vistula River below Warsaw, W84-03154 5C

Oxygen Consumption and Survival of Asellus aquaticus L. (Crustacea) in Vistula River Section Highly Polluted by Municipal Sewage, W84-03155 5C

Alterations in Gill Epithelial Morphology of Yearling Sunapee Trout Exposed to Acute Acid Stress, W84-03317 5C

Chronic Effects of Coal-Liquid Dispersions on Fathead Minnows and Rainbow Trout, W84-03319 5C

Phenol Tolerance in Populations of Mosquitofish from Polluted and Nonpolluted Waters, W84-03322 5C

Model of PCB in the Lake Michigan Lake Trout Food Chain, W84-03326 5B

The Influence of the Grand River on Phytoplankton Near the Northeastern Shore of Lake Erie during 1979, W84-03489 5C

A Comparative Survey of Ancylus fluviatilis (Muller) Populations in the Afon Crafnant, N. Wales, Above and Below an Input of Zinc from Mine-Waste, W84-03490 5C

WATER POLLUTION PREVENTION

Water Pollution Arising from Solid Waste (Coal, Fly Ash, Slag) Disposal, and Measures to Prevent Water Pollution, W84-03372 2B

WATER POLLUTION SOURCES

Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream, W84-03057 5B

Water Quality Consequences of Conservation Tillage, W84-03060 4D

Sources and Transport of Hydrocarbons in the Green-Duwamish River, Washington, W84-03327 5B

Model of Ion Equilibrium in Aqueous Solutions of Fly Ash in the Context of Prediction of Ground and Surface Water Contamination, W84-03381 5B

The Effects of Coal Combustion and Acidification on the Cadmium Exposure of the Swedish Population, W84-03389 5B

Mine Drainage and Rock Type Influences on Eastern Ohio Stream Water Quality, W84-03391 5B

Loading Functions for Predicting Nutrient Losses from Complex Watersheds, W84-03400 5B

Land Use Pressures on Coastal Estuaries in Atlantic Canada, W84-03426 5B

Oil and Grease in Urban Stormwaters, W84-03470 5B

Reliability of River-Treatment Plant Systems, W84-03474 5C

WATER POTENTIALS

Statistical Assessment of Some Errors in Thermocouple Hygrometric Water Potential Measurement, W84-03215 7B

Significance of Accelerated Leaf Senescence at Low Water Potentials for Water Loss and Grain Yield in Maize, W84-03285 2I

WATER PROPERTIES

The Role of Soil in Determining Surface Water Composition, W84-03384 2K

WATER QUALITY

Studies on Bacteriological Quality of Nainital Lake Water in Different Seasons, W84-02989 5B

Water Quality Consequences of Conservation Tillage, W84-03060 4D

PRINCETON UNIV., NJ. DEPT. OF CIVIL ENGINEERING.
Direct Parameter Identification of Fractured Porous Medium,
W84-03457 2G

PUNJAB AGRICULTURAL UNIV., LUDHIANA (INDIA). DEPT. OF SOILS.
Effect of Small Irrigation Amounts on the Yield of Wheat,
W84-03434 3F

PURDUE UNIV., LAFAYETTE, IN.
Color Patterns and Water Table Levels in Some Indiana Soils,
W84-03181 2G

PURDUE UNIV., LAFAYETTE, IN. DEPT. OF AGRONOMY.
What is Conservation Tillage,
W84-03058 4D

Theoretical and Measured Evaporation Rates from an Exposed Piche Atmograph,
W84-03213 2D

PURDUE UNIV., LAFAYETTE, IN. SCHOOL OF CIVIL ENGINEERING.
Analysis and Modeling of Palmer's Drought Index Series,
W84-03344 2B

QUEBEC UNIV., MONTREAL. DEPT. DE CHEMIE.
Rainbow Trout and Human Cells in Culture For the Evaluation of the Toxicity of Aquatic Pollutants: A Study With Cadmium,
W84-03114 5C

QUEBEC UNIV., RIMOUSKI. DEPT. OF OCEANOGRAPHY.
Chemistry of Dissolved and Particulate Material in the Estuary of the Rimouski River (Contribution a L'Etude Chimique du Materiel Dissous et Particulaire de L'Estuaire de la Riviere Rimouski),
W84-03108 2L

RAYMOND KAISER ENGINEERS, INC., OAKLAND, CA.
Chlorination-Filtration for Iron and Manganese Removal,
W84-03142 5F

READING UNIV. (ENGLAND). DEPT. OF AGRICULTURAL BOTANY.
Simulation of a Rainfall Record for the Site of a New Agricultural Development: An Example from Northern Syria,
W84-03211 2B

RHODE ISLAND UNIV., KINGSTON. CENTER FOR OCEAN MANAGEMENT STUDIES.
Baseline Delimitations and Maritime Boundaries,
W84-03237 6E

RIJKSINSTITUUT VOOR DRINKWATERVOORZIENING, LEIDSCHENDAM (NETHERLANDS). CHEMICAL BIOLOGICAL DIV.
Relative Liver Weights and Xenobiotic-Metabolizing Enzymes of Fish From Polluted Surface Waters in the Netherlands,
W84-03116 5C

Benthic Macroinvertebrates and Water Quality Assessment: Some Toxicological Considerations,
W84-03118 5C

The Microtox* as an Alternative Assay in the Acute Toxicity Assessment of Water Pollutants,
W84-03120 5C

Monitoring the Rivers Rhine and Meuse in the Netherlands for Toxicity,
W84-03121 5C

ROCKEFELLER UNIV., NEW YORK.
A Stochastic Age-Structured Population Model of Striped Bass (Morone saxatilis) in the Potomac River,
W84-03023 2H

ROCKY MOUNTAIN FOREST AND RANGE EXPERIMENT STATION, FORT COLLINS, CO.
Cattle Grazing Impact on Surface Water Quality in a Colorado Front Range Stream,
W84-03057 5B

ROSTOCK UNIV. (GERMAN D.R.).
Production and Distribution of Benthic Microalgae in the Littoral Sediments of Mikolajskie Lake,
W84-03133 2H

ROYAL INST. OF TECH., STOCKHOLM (SWEDEN). DEPT. OF INORGANIC CHEMISTRY.
Studies on the Leaching and Weathering Processes of Coal Ashes,
W84-03377 5E

ROYAL INST. OF TECH., STOCKHOLM (SWEDEN). DEPT. OF WATER RESOURCES ENGINEERING.
A Stochastic Model of a Fractured Rock Conditioned by Measured Information,
W84-03414 8E

RUTGERS - THE STATE UNIV., NEW BRUNSWICK, NJ. DEPT. OF CIVIL AND ENVIRONMENTAL ENGINEERING.
Model of Mississippi River Pool: Mass Transport,
W84-03084 2E

RUTGERS - THE STATE UNIV., PISCATAWAY, NJ. DEPT. OF CIVIL AND ENVIRONMENTAL ENGINEERING.
Model of Mississippi River Pool: Dissolved Oxygen,
W84-03085 2H

SAN DIEGO STATE UNIV., CA. DEPT. OF BIOLOGY.
Freshwater Impacts in Normally Hypersaline Marshes,
W84-03036 2L

SAN DIEGO STATE UNIV., CA. DEPT. OF GEOGRAPHY.
The 'Decade of the Environment' in the U.S.S.R.,

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 17, NUMBER 10
OCTOBER 1984

DEPOSITORY
SEP 18 1984
UNIVERSITY OF ILLINOIS
AT URBANA-CHAMPAIGN

W84-03505 -- W84-04187
CODEN: SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 10
OCTOBER 1984

W84-03505 -- W84-04187

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

leaching from strip-mined lands would facilitate the development of sound management practices by allowing assessment of each technique for any given condition to be made in minutes rather than years. A model describing the long-term oxidation of pyrite and the removal of reaction products from reclaimed coal strip mines using both direct-oxygen and ferric iron oxidation of pyrite is considered. The pyrite oxidation rate is assumed to be controlled by first-order, solid-liquid kinetics and the rate of simple diffusion of oxidant into reactive, coarse, stone fragments. The oxygen supply into the reclaimed profile is considered to be governed by one-dimensional gas diffusion. Ferric iron is produced by both purely chemical and bacterial oxidation of ferrous iron. Activity of the iron-oxidizing bacteria is controlled by the energy available from ferrous oxidation, as measured by the ferric/ferrous ratio, and from a combination of potentially inhibiting factors: the oxygen concentration in the spoil air, the hydrogen ion concentration in solution, and the soil temperature. Bacterial activity and pyrite oxidation are linked through a shared environment. The side reactions considered include the complexation and precipitation of ferric iron and the interaction between hydrogen ion in solution and the spoil matrix. Soluble reaction products are removed from the reclaimed profile by percolating water. (Murphy-IVI)

ACID MINE DRAINAGE FROM RECLAIMED COAL STRIP MINES 2. SIMULATION RESULTS OF MODEL,
Agricultural Research Service, Phoenix, AZ. Water Conservation Lab.
D. B. Jaynes, H. B. Pionke, and A. S. Rogowski.
Water Resources Research, Vol. 20, No. 2, p 243-250, February, 1984. 11 Fig, 3 Tab, 6 Ref.

Descriptors: *Acid mine drainage, *Strip mines, *Simulation analysis, Model studies, Mathematical studies, Pyrite, Oxidation, Oxygen balance, Hydrogen ion concentration.

Acid mine drainage from reclaimed coal strip mines is simulated by use of a comprehensive model. The simulated concentrations of key components are well within the ranges of measured values from reclaimed mines. In systems without iron-oxidizing bacteria the simulations indicate that oxygen is the only important oxidizer of pyrite. The oxidation of ferrous to ferric iron by purely chemical means is too slow to affect the overall oxidation rate of pyrite and is not important in these systems. For the typical physical parameters used here the diffusion rate of oxygen is the primary factor controlling the rate of pyrite oxidation. The pyrite oxidation rate is decreased by decreased air-filled porosity, by increased tortuosity of the oxygen diffusion path, by increased size of the spoil fragments, and by burying the pyritic material at deeper depths. Where oxygen resupply is not limiting the results indicate that iron-oxidizing bacteria can greatly increase the rate of pyrite oxidation. Whether or not bacteria are important in these zones depends primarily on the pH of the spoil solution. In the optimal pH range, between reduced bacterial efficiency and reduced ferric iron solubility ($2.0 < \text{or} = \text{pH} < \text{or} = 3.0$), the pyrite oxidation rate is accelerated by bacterially produced ferric iron. The extent and type of chemical reactions between H(+), produced by pyrite oxidation, and the spoil matrix appears to be crucial in establishing the pH of the spoil solution. (Murphy-IVI)

PROBLEM OF PERMISSIBLE COVARIANCE AND VARIOGRAM MODELS,
Ecole Nationale Superieure des Mines de Paris (France). Centre de Geostatistique et de Morphologie Mathematique.
G. Christakos.
Water Resources Research, Vol. 20, No. 2, p 251-265, February, 1984. 5 Fig, 33 Ref.

Descriptors: *Permissible Covariance, *Variogram models, Mathematical models, Hydrologic models, Geostatistics, Polygonal models.

The covariance and variogram models (ordinary or generalized) are important statistical tools used in various estimation and simulation techniques which have been recently applied to diverse hydrologic problems. For example, the efficacy of kriging, a method for interpolating, filtering, or averaging spatial phenomena, depends, to a large extent, on the covariance or variogram model chosen. The aim of this article is to provide the users of these techniques with convenient criteria that may help them to judge whether a function which arises in a particular problem, and is not included among the known covariance or variogram models, is permissible as such a model. This is done by investigating the properties of the candidate model in both the space and frequency domains. This investigation covers stationary random functions as well as intrinsic random functions (i.e., nonstationary functions for which increments of some order are stationary). Then, based on the theoretical results obtained, a procedure is outlined and successfully applied to a number of candidate models. In order to give this procedure a more practical context, 'stereological' equations are employed that essentially transfer the investigations to one-dimensional space, together with approximations in terms of polygonal functions and Fourier-Bessel series expansions. There are many benefits and applications of such a procedure. Polygonal models can be fit arbitrarily closely to the data. Also, the approximation of a particular model in the frequency domain by a Fourier-Bessel series expansion can be very effective. (Murphy-IVI)

NONLINEAR STOCHASTIC MODEL OF RAINFALL RUNOFF PROCESS,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
S. G. Rao, and R. A. Rao.
Water Resources Research, Vol. 20, No. 2, p 297-309, February, 1984. 7 Fig, 7 Tab, 18 Ref. OWRT project C-3277.

Descriptors: *Nonlinear stochastic models, *Rainfall-runoff relationships, Rainfall, Runoff, Forecasting, Rough River, Kentucky.

A nonlinear stochastic model is proposed to model the rainfall runoff process in which higher order derivatives of rainfall are used in addition to the magnitude of rainfall as inputs. The rainfall, runoff, and derivatives of rainfall are considered as stochastic. The model consists of several subsystems in parallel. The first subsystem utilizes the observed rainfall and runoff as input and output, respectively. The subsequent subsystems use higher order derivatives of rainfall as input and forecast error from the previous subsystems as output. The subsystems improve the performance of the overall model by using higher order derivatives of input. The error in forecasting the runoff is progressively reduced by each subsystem. The method of analysis and parameter estimation of each of the subsystems are the same except that different inputs and outputs are used to characterize the subsystems. The optimal output of each of the subsystems is computed by minimizing the corresponding mean square error, and the estimation procedure is based on the statistical theory of filters involving the marginal and joint probability density functions of rainfall, runoff, and rainfall derivative sequences. The model is tested using daily rainfall runoff data from the Rough River basin in Kentucky. Testing the residuals of the model for whiteness is emphasized in order to improve the prediction performance of the model. (Murphy-IVI)

RAINFALL-RUNOFF IN SOIL EROSION WITH SIMULATED RAINFALL, OVERLAND FLOW AND COVER,
M. J. Singer, and P. H. Walker.
Australian Journal of Marine and Freshwater Research, Vol. 21, No. 2, p 109-22, 1983. 3 Fig, 6 Tab, 26 Ref.

Descriptors: *Rainfall-runoff relationships, *Soil erosion, *Simulated rainfall, *Overland flow, Straw cover, Agricultural runoff, Surface runoff, Rainfall impact, Rainfall intensity, Sheet erosion.

The relative importance of rainsplash, rain-flow transportation and overland flow alone in sheet erosion may be determined by using a flume and rainfall simulator with soil materials. The 20-100 mm portion of a yellow podzolic soil (Albaqualf) from the Ginninderra Experiment Station (A.C.T.) was used in a rainfall simulator and flume facility to elucidate the interactions between raindrop impact, overland water flow and straw cover as they affect soil erosion. A replicated factorial design compared soil loss in splash and runoff from 50 and 100 mm/h rainfall, the equivalent of 100 mm/h overland flow, and 50 and 100 mm/h rainfall plus the equivalent of 100 mm/h flow, all at 0, 40 and 80% straw cover on a 9% slope. As rainfall intensity increased, soil loss in splash and runoff increased. Within cover levels, the effect of added overland flow was to decrease splash but to increase total soil loss. This is due to an interaction between raindrops and runoff which produces a powerful detaching and transporting mechanism within the flow known as rain-flow transportation. Airsplash is reduced, in part, because of the changes in splash characteristics which accompany changes in depth of runoff water. Rain-flow transportation accounted for at least 64% of soil transport in the experiment and airsplash accounted for no more than 25% of soil transport. The effects of rainfall, overland flow and cover treatments, rather than being additives, were found to correlate with a natural log transform of the soil loss data. The findings have relevance to predictive models such as CREAMS which are based on erosional processes. (Murphy-IVI)

SMEMAX. CAUTION,
Missouri Univ.-Rolla. Dept. of Civil Engineering.
J. A. Westphal.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 209-218, March, 1984. 5 Tab, 7 Ref.

Descriptors: *SMEMAX, Model studies, Computer programs, Mathematical equations, Mathematical models, Mathematical studies, Flood data, Flood hydrographs, Comparison studies, Flood frequency.

The intrinsic appeal of SMEMAX is that it seems to obviate the need for choosing a 'best fit' distribution from among several possible options. The SMEMAX Transformation was tested on samples generated from log-Pearson Type III and Gumbel Extreme Value Type 1 distributions. Although the transformation results in a distribution with a skew near zero, it is not a true normal distribution. The coefficients of kurtosis for the transformed distributions are always less than three and when the parent distribution approaches a reverse-J shape, the transformed distribution is bimodal. When the skew coefficient of the logarithms of events is -0.5 or greater for samples from the log-Pearson Type III distribution, the SMEMAX procedure underestimates the magnitude of events with return periods of 50 yr and greater. Similarly, SMEMAX estimates of rare events from the Gumbel Extreme Value Type 1 distribution are always too low. Based on comparisons made in this study, it is likely that application of SMEMAX procedures to any skewed distribution will result in biased estimates of the magnitude of rate events and if the skew is positive the estimates will be too low. SCS URBAN PEAK FLOW METHODS,
Maryland Univ., College Park. Dept. of Civil Engineering.
R. H. McCuen, W. J. Rawls, and S. L. Wong.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 290-299, March, 1984. 2 Fig, 4 Tab, 8 Ref.

Descriptors: *Hydrologic models, *Flood peak, Flood basins, Flood recurrence interval, Flood forecasting, Flood frequency, Maximum probable floods, Flood hydrographs, Flood plain management, Urban watersheds, Urban hydrology, Urban areas.

The peak flow hydrologic methods of the U.S. Soil Conservation Service (SCS) (as contained in their Technical Release No. 55) are widely used for planning and design on small urban watersheds. The urbanization factors of the TR-55 methods (i.e., the lag factors for the graphical method and the peak factors for the chart method) were apparently not directly based on analyses of measured data and have not previously been systematically tested. Therefore, the objective of this study was to test the TR-55 methods and recalibrate the urbanization factors if the methods were found to be biased. A data base was compiled for 51 small urban watersheds under 4,000 acres (1,600 ha) in the United States. The annual maximum flood series were used to develop Log-Pearson Type III frequency curves, from which peak discharge rates were estimated for the following return periods: 2-yr, 5-yr, 10-yr, 25-yr, 50-yr, and 100-yr. The bias and accuracy of the SCS methods were evaluated using the Log-Pearson Type III estimate as the expected true value. The results indicate that no urbanization correction factors are needed for the graphical methods when time of concentration is determined using the velocity method. The adjustment factor for the hydraulic length modification of the channel only, and the hydraulic length modification adjustment relationship is not a function of curve number. The curve for a curve number of 90 provides the most accurate prediction. (Murphy-IVI)

COLUMBIA RIVER HYBRID MODELING SYSTEM,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Estuaries Div.
W. H. McAnally, Jr., J. V. Letter, Jr., J. P. Stewart, W. A. Thomas, and N. J. Brogdon, Jr.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 300-311, March, 1984. 3 Fig, 13 Ref.

Descriptors: *Columbia River, *Model studies, Mathematical models, Shoals, Sedimentation, Sediment control, Sediment transport, Forecasting, Hydrologic models, Oregon.

The Army Corps of Engineers maintains a 48-ft deep by 2,600-ft wide navigation channel through the estuary entrance of the Columbia River, Oregon, which is protected by jetties. Annual maintenance dredging of 4,800,000 cu yd in the entrance has led the Army Engineer District, Portland (NPP), to seek means of reducing shoaling in the entrance channel. A hybrid modeling method for predicting waterway sedimentation was developed and applied to the Columbia River estuary. The method uses physical hydraulic models, two dimensional (2-D) numerical models, and analytical techniques in an integrated solution scheme. The hybrid modeling system consisted of a large physical model of the estuary, RMA-2V, a depth-integrated numerical model for sediment transport, and a collection of analytical methods. By using each method to address those phenomena that it is best able to describe, an improved modeling technique is created. (Murphy-IVI)

COMPLEX POLYNOMIAL APPROXIMATION OF THE LAPLACE EQUATION,
California Univ., Irvine. Dept. of Civil Engineering.
T. V. Hromadka, II, and G. L. Guymon.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 329-339, March, 1984. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *LaPlace Equation, *Mathematical equations, *Polynomials, Surface flow, Porous media, Groundwater, Hydrologic model, Boundary conditions, Freezing, Frozen ground, Soil-water freezing.

A method of approximating the solution of the LaPlace equation in two-dimensions is presented. The numerical approach is to determine a complex variable polynomial which satisfies the specified boundary conditions along a simple closed contour. Since the method is simple to apply to time-stepped, quasi-steady state saturated ground water problems or moving boundary problems, a significant savings in computational effort over other boundary integral equation methods is available. Applications to a free water surface problem and a moving boundary problem are presented. Error bounds and model stability are considered. (Author's abstract)

GENERALIZED MODEL FOR STORMWATER RUNOFF HYDROGRAPHS,
New Jersey Agricultural Experiment Station, New Brunswick.
C. G. Uchrin, and W. J. Weber, Jr.
Journal of Environmental Science and Health, Vol. A19, No. 1, p 67-82, 1984. 7 Fig, 5 Tab, 4 Ref.

Descriptors: *Model studies, *Runoff, *Hydrographs, Storms, Rainfall-runoff relationships, Drainage basins, Rainfall distribution, Michigan.

The most direct method for obtaining detailed stormwater runoff quantity and quality for specific drainage areas is by direct sampling and analysis, but this is often impossible to perform this for all inputs to a receiving water body. An empirical model is presented for generating runoff hydrographs for nationwide drainage basins as a function of the drainage area, population density, and rainfall excess distribution. A computer program was written incorporating the analysis. The model was applied to a study area in southeastern Michigan. A water quality model was constructed for the Huron River-Ford Lake-Belleville Lake system. Detailed sampling and analysis of each storm drain input source was unfeasible, so the runoff quantity model described was used in conjunction with a separate quality submodel to generate time variable pollutant loadings. (Baker-IVI)

PREDICTIVE AGGREGATION MODELS IN HYDROLOGY,
Technical Univ. of Istanbul (Turkey).
Z. Sen.
Nordic Hydrology, Vol. 14, No. 1, p 19-32, 1983. 4 Fig, 1 Tab, 22 Ref.

Descriptors: *Model studies, *Hydrologic models, Prediction, Stochastic processes, Rainfall-runoff relationships, Flow.

A predictive aggregation model with recursive parameter estimations has been proposed. Necessary estimation formulations have been explicitly derived and then applied to monthly flows. The estimation procedure does not impose any restrictions concerning either the parameter matrices such as positive semidefiniteness or the standardization of observations to have zero mean. The estimations are unbiased and have the minimum variance as properties of the Kalman filter. The overall advantages of the model are that the computations are based on simple matrix algebra, that there is no need for an inverse matrix operation provided that the measurement matrix is scalar, that the parameters and states are estimated online as the data becomes available, that there is no need to preserve all the data in the computer memory, and that computations can be performed in a short time. Lower-order events can be generated which add up the the given higher-order events without any external intervention. (Baker-IVI)

KALMAN FILTER EMPIRICAL FITTING ON MONTHLY RAINFALL-RUNOFF RESPONSES,
National Technical Univ., Athens (Greece).
M. Mimikou.
Nordic Hydrology, Vol. 14, No. 2, p 93-112, 1983. 8 Fig, 4 Tab, 7 Ref.

Descriptors: *Rainfall-runoff relationships, *Kalman filters, Statistical methods, Model studies, Prediction, Runoff, River basins, Rivers, Greece, Aliakmon River, Acheloos River, Snowfall.

The majority of the methods for fitting rainfall-runoff Kalman filters use the statistical characteristics of the input (rainfall) and the output (runoff) series according to the systems analysis and control theory methodology. The presented empirical method of fitting takes into account additional input information and improves the knowledge about the hydrological system, without changing the simple two-variable structure of the filter. This information consists of the percentage of snowfall into the monthly basin rainfall, the magnitude of basin rainfall at month t in comparison to the rainfall at month t-1 (increasing, constant, or decreasing) and the amount of basin rainfall associated with basin's moisture and runoff characterisics. The Kalman filter empirically fitted on monthly rainfall-runoff responses of the Alaikmon and Acheloos river basins in Greece is shown to be more accurate and adequate than the automatically fitted filter by using conventional statistical methods. The filter has been used in hydroelectric energy studies of the area, where accurate runoff estimation from rainfall was necessary. (Baker-IVI)

COMPUTER CONTROL FOR IRRIGATION-CANAL SYSTEM,
Stone and Webster Engineering Corp., Denver, CO.
D. D. Zimbelman, and D. D. Bedworth.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 1, p 43-59, March, 1983. 10 Fig, 1 Tab, 16 Ref.

Descriptors: *Irrigation canals, *Computer models, Computers, Algorithms, Water conveyance, Open-channel flow, Water distribution, Comparison studies.

The objective was to develop an algorithm for the computerized control of an open-channel water distribution system that would allow the system to be operated on a demand basis rather than on a scheduled basis. The algorithm, which was of necessity empirical, is an adaption of proportional downstream control. The input to algorithm is the water surface upstream of each control structure. The output from the algorithm is an adjustment in gate opening, implemented at the adjacent upstream control structure. The adequacy of the algorithm was verified by simulating the interaction between the algorithm and two different typical canal systems. These simulations were used to first establish viability of the algorithm in an automated control environment, and secondly to compare automated control to manual control. The control algorithm is capable of controlling an open-channel water distribution system at a higher level of efficiency than manual control. Efficiency, under manual control, is measured in terms of the stability of the water surface elevations within the system. (Murphy-IVI)

PRECIPITATION AND RUNOFF ON EIGHT NEW ENGLAND BASINS DURING EXTREME WET AND DRY PERIODS,
Science and Education Administration, University Park, PA. Northeast Watershed Research Center.
R. J. Deangelis, J. B. Urban, W. J. Gburek, and M. A. Contino.
Hydrological Sciences Journal, Vol. 29, No. 1, 1984. 7 Fig, 4 Tab, 23 Ref.

Descriptors: *Precipitation, *Rainfall-runoff relationships, New England, Runoff, Seasonal variations, Watersheds, Evapotranspiration, Sleepers River Watershed, Vermont.

Extreme wet and dry 12 month periods occurred during the 20 years of hydrological data collections made at the Sleepers River Watershed (Vermont). Extrapolation of a nearby 87-year precipitation record to the basin was useful in determining the deviations of those extreme periods from normal. Seasonal water-input and runoff increased with elevation for both the wet and the dry period. For both water-input and runoff, the rate of increase was greater during the wet period. The slope of the water-input and runoff regression lines is related to the magnitude of the water-input. Variations in the measured flow at the eight subbasins examined were due to the complex basin and climatological conditions typical of New England

basins. However, the variations may be adequately described using elevation alone as the index. The fact that the increase in summer precipitation with elevation was significantly greater than the increase in runoff suggests that evapotranspiration increased with elevation. The greater magnitude of precipitation at higher elevations results in more potential and thus more actual evapotranspiration. (Baker-IVI)

WATER, SEDIMENT AND NUTRIENT MOVEMENT IN FORESTED AND NON-FORESTED CATCHMENTS IN KUMAUN HIMALAYA,
Kumaun Univ., Naini Tal (India). Dept. of Botany.
A. N. Pandey, P. C. Pathak, and J. S. Singh.
Forest Ecology and Management, Vol. 7, No. 1, p 19-29, November, 1983. 6 Tab, 16 Ref.

Descriptors: *Forest soils, *Overland flow, *Soil loss, *Nutrients, *Himalaya, Soil deposition, Landslides, Cultivation, Monsoons, Vegetation, Storm seepage, Calcium, Potassium, Phosphorus, Nitrogen.

Overland flow, and soil and nutrient loss were assessed for four sites under original forest cover, and for four sites affected by soil deposition, landslide or cultivation in the Kumaun Himalaya during the 1981 and 1982 monsoon seasons. Overland flow was positively related with rainfall quantity and intensity and was reduced by the growth of ground vegetation during the later months of the monsoon season. Average overland flow was only 0.50% of the total incident rainfall indicating that these catchments are subsurface flow systems. Soil loss was positively related with overland flow, both being greater for non-forested compared to forested sites. Rainfall added a significant amount of nutrients. This extra system input was greater than loss through overland flow and runoff soil. The forested sites lost less nutrients compared to non-forested sites. The loss of nutrients was in the order: Ca > K > P > N. The forests of the catchments in Himalaya should be protected to avoid the impairment of hydrologic processes. (Author's abstract)

EFFICIENT AND ROBUST METHOD FOR ESTIMATING UNIT HYDROGRAPH ORDINATES,
University Coll., Galway (Ireland). Dept. of Engineering Hydrology.
M. Bruen, and J. C. I. Dooge.
Journal of Hydrology, Vol. 70, No. 1-4, p 1-24, 1984. 11 Fig, 19 Ref, 2 Append.

Descriptors: *Unit hydrographs, *Smoothed least squares, Mathematical studies, Flood hydrographs, Matrix structure, Computers, Hydrographs.

The coefficient matrix for the 'normal equations' for least-squares estimates of discrete unit hydrographs (DUH) is symmetric Toeplitz. Smoothed least squares is an effective way of combating the instability of DUH estimates due to numerical ill-conditioning. This matrix structure can be used to reduce both the data storage and arithmetic computation requirements of computer programs for estimating DUHs. The method is particularly useful for small computers when memory space is limited or when large amounts of data are involved. The algorithm can be used to provide smoothed least-squares estimates of the DUH using a single extra arithmetic addition. Estimates of DUH's for multiple-event data can easily be calculated. This method gives the user a degree of control over the estimation process which allows the exercise of subjective judgement. Computer programs are presented for both the single-event and multiple-event case. The utility of the smoothed estimates is illustrated using real data which would give unrealistic ordinary least-squares estimates. The data are for three separate flood events in the Almond and Almondell, Scotland catchment. The catchment has an area of 229 sq km. (Moore-IVI)

STATISTICAL ANALYSIS OF WEATHER-TYPE RUNOFF PHENOMENA IN AN ALPINE ENVIRONMENT,
Vrije Univ., Amsterdam (Netherlands). Inst. of Earth Sciences.
A. A. Van de Griend, and E. Seyhan.
Journal of Hydrology, Vol. 70, No. 1-4, p 51-69, 1984. 11 Fig, 2 Tab, 11 Ref.

Descriptors: *Alpine regions, *Weather, *Runoff, *River Ahr, *Italy, Precipitation, Temperature, Snowmelt, Glaciers, Temporal distribution, Atmospheric circulation, Autocorrelation.

Each class of weather types has its own characteristic population of daily runoff data and sequences of daily runoff. In order to obtain a better insight into the combined effect of weather types working on the complex hydrologic system, several aspects of runoff were analyzed with respect to the distribution of daily runoff occurrences and their time sequence. For this purpose, atmospheric circulation types were classified into hydrologically relevant classes of weather types using a classification developed for the European Alpine region. Hydrologic and meteorological data from the 23-yr period 1953-1975 for the Alpine pluvio-nivo-glacial catchment of the River Ahr (Italy) were used for the analyses. Antecedent hydrologic conditions are subject to large year-to-year changes, especially during the months with snow- and glacier-melt. The magnitude of runoff during each particular class of weather types is largely governed by autocorrelation (related to the characteristic times of the systems active during preceding classes and thus related to the preceding weather types) and by antecedent conditions, rather than by the weather types themselves. The influence of a weather class displays a distinct dependency of the time elapsed since the start of the particular class. On the average, the influence does not become manifest until after a 2-3 day period. (Moore-IVI)

NEW TECHNIQUE FOR THE ANALYSIS OF EXTREME RAINFALL WITH APPLICATION TO LAGOS METROPOLIS, NIGERIA,
Lagos Univ. (Nigeria). Faculty of Engineering.
E. S. Oyegoke, and J. O. Sonuga.
Nordic Hydrology, Vol. 14, No. 3, p 127-138, 1983. 2 Fig, 6 Tab, 9 Ref.

Descriptors: *Rainfall, *Storm runoff, *Statistical analysis, *Lagos, *Nigeria, Storms, Entropy, Urban areas, Simulation.

A case study is made of storm rainfall analysis for Lagos metropolis using the available rainfall data for Ikeja, Oshodi and Lagos Mainland. The principle of maximum entropy is viewed as an alternative technique for the parameter estimation of the Extreme Value Type-1 (EV1) distribution or Gumbel distribution often used for the analysis and forecast of extreme events. For comparison purposes, the parameters of the EV1 distribution are also obtained using the Maximum Likelihood Method, the latter being one of the most reliable techniques and perhaps the most widely used for parameter estimation of the EV1 distribution. This exercise makes it possible to demonstrate in some ways the superiority of the maximum entropy method over existing methods used for statistical simulation of extreme events. (Baker-IVI)

REGIONAL RAINFALL CHEMISTRY IN MINNESOTA AND WEST CENTRAL WISCONSIN,
Minnesota Univ., St. Paul. Dept. of Plant Pathology.
G. C. Pratt, M. R. Coscio, and S. V. Krupa.
Atmospheric Environment, Vol. 18, No. 1, p 173-182, 1984. 3 Fig, 5 Tab, 32 Ref.

Descriptors: *Rainfall, *Water pollution effects, *Minnesota, *Wisconsin, *Water chemistry, *Acid rain, Sulfates, Nitrates, Ammonium, Calcium, Acidity.

During May-October 181, automatic, refrigerated, sequential, precipitation samplers were operated at seven locations in Minnesota and Wisconsin. Sites were dispersed in the study area to sample within three major types of ecosystems found in the region. At the northeastern Minnesota sites, an area considered vulnerable to acidic precipitation, concentrations of all major ions except hydrogen were generally lower than at other sites. The higher rainwater acidity at the northern sites appears to be a function of the lower concentrations of alkaline cations such as calcium (2+) ions and ammonium. However, the best single predictor of acidity was sulfate. So-called clean rain may be slightly more acidic than pH 5.6, as indicated by the analysis of the relationships between pH and concentrations of the major ions. Air parcel back trajectories showed that rain in air masses arriving from the northwest quadrant contained the lowest concentrations of sulfate and nitrate, while the majority of rainfall sulfate and nitrate arrived from the south quadrant. STUDY FOR IMPROVING PRECIPITATION OCCURRENCES MODELLING WITH A MARKOV CHAIN,
National Technical Univ., Athens (Greece).
M. Mimikou.
Journal of Hydrology, Vol. 70, No. 1-4, p 25-33, 1984. 1 Fig, 3 Tab, 7 Ref.

Descriptors: *Precipitation, *Markov chain, *Mathematical models, *Greece, Stochastic process, Seasonal variation, Simulation.

Daily precipitation occurrences and their monthly wet-days' sums of seven precipitation stations in Greece are modelled with a Markov chain of seasonally varying order. A method is proposed based on the conjunctive use of a low-order autoregressive stochastic model with a Markov chain, which significantly improves the Markov chain's efficiency for modelling daily precipitation occurrences and their monthly wet-days' sums. With the proposed method for modifying the generation procedure with a Markov chain, not only the monthly wet-days' sums but also the daily precipitation occurrences modelling are significantly improved. The improvement is expected, since this procedure utilizes more information from the historical data; the standard deviation of the sum of wet days is indirectly taken into account. The modified dry day-wet day simulation sequences represent better the historical sequences than the unmodified ones. This is due to the successful selection of the correct criterion for properly distributing inside the month the added or subtracted wet days, than to the additional historical monthly statistical information which is brought into the model. ICE FORECASTING MODEL FOR LAKE ERIE,
Ecology and Environment, Inc., Buffalo, NY.
S.-H. Chieh, A. Wake, and R. R. Rumer, Jr.
Journal of Waterway, Port, Coastal and Ocean Engineering, Vol. 109, No. 4, p 392-415, November, 1983. 14 Fig, 23 Ref. Great Lakes Environmental Research Laboratory contract NA80RAC00148.

Descriptors: *Lake ice, *Forecasting, *Lake Erie, Navigation, Model studies, Mathematical models, Thermodynamics, Wind, Ice cover, Ice drift, Iced lakes.

A previously developed Great Lakes ice forecasting model for winter navigation aid has been calibrated using observed data from specific Lake Erie

ice transport events. The model is based on the macroscopic continuum hypothesis for the fragmented ice field and the internal ice stress is represented by a viscous-plastic type constitutive law. The external driving force includes the time-dependent wind and water current fields as well as the thermodynamic source/sink terms for the ice mass conservation. By adjusting the model coefficients employed in the constitutive equations and the thermodynamic factors, the computed results are in reasonable agreement with the short-term observations for the 1978-79 ice season in Lake Erie. Major findings include the profound effects of the wind-driven water currents and the ice melt at the ice-water interface on the ice regime of Lake Erie during the late stage of the ice season. CORRECTION OF MEASURED PRECIPITATION IN THE ALPS USING THE WATER EQUIVALENT OF NEW SNOW,
Eidgenoessische Technische Hochschule, Zurich (Switzerland).
B. Sevruk.
Nordic Hydrology, Vol. 14, No. 2, p 49-58, 1983. 3 Fig, 3 Tab, 14 Ref.

Descriptors: *Precipitation, *Measuring instruments, *New snow, *Alps, Temperature effects, Wind, Snowfall, Air temperature.

Considerable systematic losses in winter precipitation measurements in the Alps, using heated and storage gauges, show that corrections of precipitation data are a necessity. For storage gauges the losses are related to wind speed measured near the gauge site. For heated gauges the losses are more complex due to heating and blowing out of snow. The Hellmann heated siphon pluviograph with wind shield showed 56% less winter precipitation than measured on a snow board at an altitude of 2,540 m a.s.l. For the Swiss heated tipping bucket gauge and the storage gauge, precipitation was 31% less. Rough assessments can be made from the portion of snowfall on days with the temperature less than minus 8 degrees C. The results can be used to make a preliminary adjustment of precipitation sums at Alpine gauge sites where wind speeds and temperature can be assessed. (Baker-IVI)

GROWTH MODEL FOR BLACK ICE, SNOW ICE AND SNOW THICKNESS IN SUBARCTIC BASINS,
Merentutkimuslaitos, Helsinki (Finland).
M. Lepparanta.
Nordic Hydrology, Vol. 14, No. 2, p 59-70, 1983. 5 Fig, 1 Tab, 22 Ref.

Descriptors: *Ice thickness, *Model studies, *Subarctic zone, Snow, Ice, Black ice, Density, Temperature, Snowfall, Heat flux.

A model is presented for the growth of ice thickness in autumn and winter. The model includes packing of snow and snow-snow ice transformation. The external input variables include the temperature of the upper surface of the ice sheet, and snowfall and heat flux from the water. Snow-covered floating ice sheet has three distinct layers of frozen water: black ice, snow ice (frozen slush), and snow. Black ice is formed from basin water only. The model predicts the thickness of black ice, snow ice and snow and the density of snow. Thermal inertia is neglected. The results are sensitive to the assumed density of freshly fallen snow and the formulation of snow metamorphism. Comparisons between observations and model calculations are given. The agreement is moderate and the need for field work on snow and ice is noted. The maximum annual ice thickness under varying external conditions is discussed. The model places emphasis on snow metamorphism and tranformation of snow into snow ice as these processes are of great importance in subarctic regions. (Baker-IVI)

SNOWPACK LIQUID WATER DETERMINATIONS USING FREEZING CALORIMETRY,
Resource Consultants, Inc., Fort Collins, CO.
E. B. Jones, A. Rango, and S. M. Howell.
Nordic Hydrology, Vol. 14, No. 3, p 113-126, 1983. 5 Fig, 28 Ref. Contract NAS5-22312, NAS5-23815, NAS5-26062.

Descriptors: *Calorimetry, *Snowpack, Measuring instruments, Forecasting, Runoff, Avalanches, Water supply.

Liquid water in a snowpack, although recognized for some time as a quantifiable parameter of hydrological significance, is not a regularly reported snowpack characteristic due to difficulties with its measurement in the field. Freezing calorimetry is discussed from presentation of theory through the application of the method including formulations for calculating the percent of liquid water in a snowpack. The freezing or cold calorimeter technique was selected primarily because it is relatively inexpensive, it is simple to use, and it is based on known and documented physical phenomena. Because a small amount of liquid water is frozen in the freezing calorimetric approach as opposed to a large amount of ice melted in the melting calorimetric method, the freezing method is more sensitive to variations in liquid water content. Silicon oil has been used successfully as the freezing agent. Consistent results can be obtained with the method, even when using newly-trained operators. Liquid water content data can be obtained approximately every 15 minutes when using two calorimeters and three operators. The freezing calorimetric approach was accurate in determining the liquid water content of the snow to within 1.0 to 2.0% by weight. (Baker-IVI)

2D. Evaporation and Transpiration

EFFECTS OF VEGETATION CONVERSION UPON WATER USE BY RIPARIAN PLANT COMMUNITIES,
Arizona Univ., Tucson. School of Renewable Natural Resources.
L. W. Gay.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-153519, Price codes: A09 in paper copy, A01 in microfiche. Completion Report, January, 1984. 175 p, 18 Fig, 14 Tab, 34 Ref, 9 Append. Project No. OWRT B-084-ARIZ (1), Contract/Grant No. 14-34-0001-9146.

Descriptors: *Evapotranspiration, *Consumptive use, *Phreatophytes, Colorado River, Plant communities, Saltcedar, Data collection, Bowen ratio system, Measurement.

Evapotranspiration was measured at two points simultaneously over a dense stand of saltcedar on the lower Colorado River with a computerized, portable Bowen ratio system. Twenty-one days of good ET data were collected during two successive years on eight different expeditions within the April-November growing season. In addition, potential ET (PET) estimates were developed for four models (radiaton, radiation and temperature, net radiation and Penman combination) using climatological data from two weather stations at nearby Blythe, California. ET from the saltcedar ranged up above 12 mm per day in midsummer. The March 23-Nov. 11 growing season total was estimated from these measurements to be 1677 mm, including 40 mm of evaporated precipitation, and annual total ET was estimated to be 1727 mm. The climatological estimates of PET were converted to actual ET (AET) by a 4th-order calibrating function developed by regressing daily totals of measured Bowen ratio ET against estimated PET. Seasonal totals of AET were in excellent agreement and averaged 1756 mm. There was little difference between the two years. The two approaches suggest that 1750 and 1800 mm are reasonable figures for growing season ET and for annual ET from well-developed saltcedar on the lower Colorado. A simple radiation model appears suitable for estimating seasonal AET totals in this region if weather data are limited, and direct measurements of ET are lacking. The report describes the instrumentation, measurements and analysis techniques needed to develop measurements of AET from climatological estimates of PET.

BARE-SOIL EVAPORATION DETERMINED IN SITU BY INFRARED THERMOMETRY,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
J. Ben-Asher, A. W. Warrick, and A. D. Matthias.
Journal of Hydrology, Vol. 69, No. 1-4, p 325-334, February, 1984. 8 Fig, 5 Ref.

Descriptors: *Evaporation, *Infrared thermometry, Surface temperature, Wind velocity, Model studies, Parametric hydrology, Hydrologic budget.

Soil properties exhibit random spatial fluctuations and most irrigation methods are systematically non-uniform. Thus the only way to account for the randomness of natural soil variations and the gradual changes in water application is to describe its components statistically instead of deterministically. This can be achieved by expressing the water balance equation terms as random variables. Bare-soil evaporation was measured in situ by infrared thermometry. Measurements were made at 25 sites on a 20 x 20-m plot. About 17 mm of water were added during the first test in March 1982 and 27 mm during a second experiment in May, both in a rainless and sunny period. The method requires measurement of wind speed, the maximum surface temperature of the test soil and a reference dry surface. Measured values of the evaporation were well correlated (r to the 2 power = 0.7) with water added, and the amount of evaporation measured for a 1-week period was of the same order of magnitude as the added water. Supporting information of surface water content by gravimetric and neutron measurements helped to complete water-balance calculations on each site. The method is proposed as a tool for evaluating spatial variability for water-balance studies in large areas. Semi-variograms were prepared for evaporation on the site and fitted by assuming a linear drift. (Murphy-IVI)

Descriptors: *Evaporation, *Soil water, *Model studies, *Remote sensing, Hydrologic budget, Evapotranspiration, Boundary conditions, Rainfall.

Actual evapotranspiration is an important quantity in climatology, hydrology, and agronomy but its characterization at regional scale appears to be rather difficult. Remote sensing techniques, which are well suited for large-scale measurements, might allow a regional approach to evaporation. A soil water transfer model has been used to estimate the soil water budget and evaporation using remotely sensed surface soil moisture data, with accuracy comparable to that of neutron probe measurements, without rain simulation. The with rain model yielded inferior estimates of evaporation and

2E. Streamflow and Runoff

water budget due partly to numerical difficulties but also to the lack of radar data between the rain events. Daily surface soil moisture data, obtained with a C band scatterometer on a bare soil, provide the upper boundary condition for the model which uses an implicit finite difference scheme to solve the nonlinear Richards equation. The soil is represented by two layers differing in hydraulic conductivity. (Baker-IVI)

Descriptors: *Transpiration, *Plant water potential, Water storage, Water loss, Transport depletion, Alfalfa, Model studies, Canopy.

Measurements made in a field of alfalfa of hourly transpiration rate and of the corresponding difference between soil and foliage water potential, showed a non-linear relation. Similar results have been reported by others and, from these, it has been concluded that the plant resistance to liquid flow is not constant, but tends to decrease as the flow-rate increases. However, an analysis of the data with a model that includes a water storage reservoir of variable content in the plant system, showed that the actual absorption (transpiration minus, the contribution of the reservoir-plant), rather than the rate of water loss from the crop, closely adheres to a linear model. Hence, the hydraulic resistance is shown to be constant, with a value of about 25 bar h/mm for an alfalfa crop of LAI around 3. In an appendix the method for deriving the model parameters is given in detail, together with an error analysis. (Author's abstract)

Descriptors: *Water transfer, *Canopy, Plant water potential, Lucerne, Water vapor, Water loss, Hydrologic cycle, Water deficit.

A previously presented model for water circulation within plants suggested a method for determining, from transpiration and water potential measurements, the amounts of water lost and recovered during the course of the day by the plant canopy. Applied to a lucerne canopy over a period of about twenty days, this method led to a set of plausible results which thus seem to comfirm the model's validity. As opposed to the case of other methods which apply only to the aerial parts, the data obtained here includes the root system contribution; for lucerne canopy studied, this contribution corresponds to two third of the water lost by the plant. The possibilities of increasing accuracy while simultaneously simplifying measurements are examined, as well as possible limitations in the method's application notably in the case of great soil dryness. EVAPORATION FROM SALINE LAKES: A COMBINATION EQUATION APPROACH,
Institute of Hydrology, Wallingford (England).
I. R. Calder, and C. Neal.
Hydrological Sciences Journal, Vol. 29, No. 1, p 89-97, 1984. 3 Fig, 2 Tab, 18 Ref.

Descriptors: *Saline lakes, *Evaporation, *Model studies, Mathematical equations, Dead Sea, Lakes, Temperature effects, Solutes, Solubility.

A modification is made to the conventional evaporation equation to allow the calculation of evaporation from saline lakes. The modified equation shows how, for a given set of meteorological conditions, the evaporation rate, the partitioning of available energy into sensible and latent heat, and the surface temperature, can all be related to solute concentrations. To illustrate the operation of the equation the recent and proposed changes to the hydrology of the Dead Sea were used as a case study. The meteorological inputs to the model cannot, however, be considered to be wholly independent of the activity of the water in solution. A decrease in lake temperature, caused by an increase in the activity of water in solution, will reduce long-wave back radiation from the lake thereby increasing net radiation, changing the atmospheric stability conditions and increasing the aerodynamic resistance, and modifying to some extent the temperature and humidity of the air above the lake. The magnitude of the model prediction errors will be largely determined by the uncertainties in the measurement of the meteorological input data and the estimate of the aerodynamic resistance. It is unrealistic to assume an accuracy of better than perhaps 10-15% in any of the quantities, which will result in model prediction errors of at least a similar magnitude. (Baker-IVI)

BLANEY-MORIN-NIGERIA EVAPOTRANSPIRATION MODEL,
Ahmadu Bello Univ., Zaria (Nigeria). Dept. of Agricultural Engineering.
J. O. Duru.
Journal of Hydrology, Vol. 70, No. 1-4, p 71-83, 1984. 3 Fig, 4 Tab, 12 Ref.

Descriptors: *Evapotranspiration, *Mathematical models, *Nigeria, Temperature, Relative humidity, Solar radiation, Wind, Developing countries.

In Nigeria, and perhaps in other developing countries, there is a need to compute evapotranspiration (Et) from those meteorological parameters which can be easily measured. An evapotranspiration model has been developed for application in Nigeria. The model, designated as the Blaney-Morin-Nigeria evapotranspiration model, predicts potential evapotranspiration with accuracy and consistency that are better than the Penman model, under Nigerian conditions. The proposed model implies that, under Nigerian conditions, accurate prediction of Et can be obtained from temperature, relative humidity and radiation. The effect of wind can be ignored without much loss of accuracy. This can be seen from the fact that the Blaney-Morin-Nigeria model proved to be a better predictor than the Penman model, which considers wind effects, in both a high-wind region and a low-wind region. The Blaney-Morin evapotranspiration concept may have similar potential elsewhere when given specific form with appropriate constants derived to reflect climatic peculiarities. (Moore-IVI)

INITIAL ASSESSMENT OF TIME OF TRAVEL AND MIXING THROUGH GULF ISLAND POND AND THE LOWER ANDROSCOGGIN RIVER, MAINE,
Geological Survey, Augusta, ME. Water Resources Div.
G. W. Parker, and S. Hunt.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $7.75 paper copy, $3.50 microfiche. USGS Water-Resources Investigations Report 83-4020, 1983. 53 p, 38 Fig, 6 Tab, 8 Ref.

Descriptors: *Rivers, *Marking techniques, *Reservoir, *Mixing, Hydrology, Streamflow, Tracer, Stratification, Inflow, Unsteady flow, Stratified flow, Analysis, Fluorometry, *Maine, *Time-of-travel, Androscoggin River, Gulf Island Pond.

Flow-stratification patterns were observed in Gulf Island Pond during time-of-travel studies in May and August 1980. The stratification patterns in this 70 million cubic-meter impoundment were due to a temperature differences between inflowing water and reservoir water. Separation was observed at temperature differences of 0.5 degrees C in May 1980 and 1.0 degrees C in August 1980. The pathway taken by inflowing water through the reservoir was governed by the temperature-related density forces acting between the two water masses. Data collected during August 1980 to define differences in dye concentrations with depth at two fixed profile points in Gulf Island Pond showed average water velocity to be seven times faster near the bottom than near the surface. A concept of mass flow was used to analyze data collected at sites downstream from Gulf Island Dam where flow varied rapidly with time. This report presents the mathematical derivation of controid traveltime, skewness, and percentage recovery of dye mass as determined from mass versus time curves. (USGS)

MEAN ANNUAL RUNOFF AND PEAK FLOW ESTIMATES BASED ON CHANNEL GEOMETRY OF STREAMS IN NORTHEASTERN AND WESTERN MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
C. Parrett, R. J. Omang, and J. A. Hull.
USGS Water-Resources Investigations Report 83-4046, June, 1983. 53 p, 8 Fig, 8 Tab, 24 Ref.

Descriptors: *Annual runoff, Regression analysis, Estimating equations, Peak discharge, *Mean flow, Gaging station, Active-channel width, Bankfull width, *Channel geometry, *Montana.

Equations for estimating mean annual runoff and peak discharge from measurements of channel geometry were developed for western and northeastern Montana. The study area was divided into two regions for the mean annual runoff analysis, and separate multiple-regression equations were developed for each region. The active-channel width was determined to be the most important independent variable in each region. The standard error of estimate for the estimating equation using active-channel width was 61 percent in the Northeast Region and 38 percent in the West region. The study area was divided into six regions for the peak discharge analysis, and multiple regression equations relating channel geometry and basin characteristics to peak discharges having recurrence intervals of 2, 5, 10, 25, 50 and 100 years were developed for each region. The standard errors of estimate for the regression equations using only channel width as an independent variable ranged from 35 to 105 percent. The standard errors improved in four regions as basin characteristics were added to the estimating equations. (USGS)

ESTIMATED NATURAL STREAMFLOW IN THE RIO SAN JOSE UPSTREAM FROM THE PUEBLOS OF ACOMA AND LAGUNA, NEW MEXICO,

Geological Survey, Albuquerque, NM. Water Resources Div.
D. W. Risser.
USGS Water-Resources Investigations Report 82-4096, 1982. 51 p, 10 Fig, 6 Tab, 16 Ref.

Descriptors: *Streamflow, *Streamflow depletion, *Reservoir evaporation, Rainfall-runoff relationships, Springs, Surface water records, *New Mexico, Pueblo of Laguna, Pueblo of Acoma, Bluewater Lake.

The development of surface and ground water, which began about 1870 in the upper Rio San Jose drainage basin, has decreased the flow of the Rio San Jose on the Pueblo of Acoma and the Pueblo of Laguna. The purpose of this study was to estimate the natural streamflow in the Rio San Jose that would have entered the pueblos if no upstream water development had taken place. Estimates of natural flow were based upon streamflow and precipitation records, historical accounts of streamflow, records of irrigated acreage, and empirically-derived estimates of the effects on streamflow of Bluewater Lake, groundwater withdrawals, and irrigation diversions. Natural streamflow in the Rio San Jose at the western boundary of the Pueblo of Acoma is estimated to be between 13,000 and 15,000 acre-feet per year, based on 55 years of recorded and reconstructed streamflow data from water years 1913 to 1972. Natural streamflow at the western boundary of the Pueblo of Laguna is estimated to be between 17,000 and 19,000 acre-feet per year for the same period. The error in these estimates of natural streamflow is difficult to assess accurately, but it probably is less than 25 percent. (USGS)

USE OF DIGITAL LAND-COVER DATA FROM THE LANDSAT SATELLITE IN ESTIMATING STREAMFLOW CHARACTERISTICS IN THE CUMBERLAND PLATEAU OF TENNESSEE,
Geological Survey, Nashville, TN. Water Resources Div.
E. F. Hollyday, and G. R. Hansen.
USGS Water-Resources Investigations Report 82-4059, 1983. 45 p, 4 Fig, 9 Tab, 17 Ref.

Descriptors: Hydrology, *Remote sensing, *Watersheds (basins), *Hydrologic networks, Satellites, Terrain analysis, Floods, Low flow, *Tennessee, Cumberland Plateau, *Statistical analysis, Computer processing, Multi-spectral image analysis, Multiple linear regression.

Streamflow may be estimated with regression equations that relate streamflow characteristics to characteristics of the drainage basin. A statistical experiment was performed to compare the accuracy of equations using basin characteristics derived from maps and climatological records (control group equations) with the accuracy of equations using basin characteristics derived from Landsat data as well as maps and climatological records (experimental group equations). Results show that when the equations in both groups are arranged into six flow categories, there is no substantial difference in accuracy between control group equations and experimental group equations for this particular site where drainage area accounts for more than 90 percent of the variance in all streamflow characteristics (except low flows and most annual peak logarithms). FLOODS IN KANSAS CITY, MISSOURI, AND VICINITY, AUGUST 12-13, 1982,
Geological Survey, Rolla, MO. Water Resources Div.
L. D. Becker, T. W. Alexander, and L. A. Waite.
USGS Water-Resources Investigations Report 83-4141, 1983. 35 p, 13 Fig, 4 Tab, 11 Ref.

Descriptors: *Floods, *Urban runoff, *Flash floods, *Flood peak, Surface runoff, Storm runoff, Runoff volume, Stream gages, Flood recurrence-interval, Surface water, *Missouri, Jackson County, Clay County, Cass County, *Kansas City.

On August 12-13, 1982, a nearly stationary weather front in the vicinity of Kansas City, MO, produced intense thunderstorms. Excessive rainfall (12.6 inches in Raytown, MO) caused flash flooding during the nighttime and early daylight hours. Four deaths and damages unofficially estimated in excess of $30 million, occurred in the three-county area of Jackson, Cass, and Clay counties. Peak discharges were determined at 12 current or discontinued streamflow-gaging stations and 17 miscellaneous sites. Flood peaks and volumes at many locations exceeded estimated 100-year recurrence-interval floods and equaled or exceeded the 1977 floods in some drainage basins. Significant flooding occurred in the Blue, East Fork Little Blue, and Little Blue River basins and in the Rock, Wilkerson, Sni-A-Bar, Shoal, and Big Creek drainage basins. (USGS)

CHEMICAL AND HYDROLOGIC ASSESSMENT OF THE CALOOSAHATCHEE RIVER BASIN, LAKE OKEECHOBEE TO FRANKLIN LOCK, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
H. R. La Rose, and B. F. McPherson.
USGS Water-Resources Investigations Report 83-4126, 1983. 63 p, 18 Fig, 15 Tab, 18 Ref.

Descriptors: *Nutrients, Flow, Canals, *Salinity, Algae, *Eutrophication, Caloosahatchee River, Caloosahatchee Canal, *Florida.

Annual discharge (1970-79 water years) from Lake Okeechobee to the Caloosahatchee River averaged 51 percent of the total river discharge at Franklin Lock and ranged from 10 to 71 percent of total discharge. Excluding rainfall on the river surface and upstream seepage, surface and subsurface runoff from the basin accounted for the remaining total river discharge at Franklin Lock. Nitrogen and phosphorus were in sufficient supply most of the time to support algal growth in the river. During algal blooms, however, nitrite plus nitrate nitrogen was depleted and probably became limiting. Nitrite plus nitrate was the predominant form of inorganic nitrogen in the river and in most tributaries. Average concentrations in the river were 0.18 to 0.21 milligram per liter. Average concentrations in most tributaries were less than those in the river. Average concentrations of total phosphorus in many tributaries fell within the same range as that in the river (0.08 to 0.15 milligram per liter), but some tributaries in the eastern part of the basin had greater average concentrations. (USGS)

TIME-OF-TRAVEL AND DISPERSION STUDIES, LEHIGH RIVER, FRANCIS E. WALTER LAKE TO EASTON, PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
C. D. Kauffman, Jr.
USGS Open-File Report 82-861, May, 1983. 32 p, 20 Fig, 5 Tab, 4 Ref.

Descriptors: *Tracers, *Dispersion, *Dilution, *Velocity, Streamflow, Time-of-travel, Concentration attenuation, Lehigh River, *Pennsylvania.

Results of time-of-travel and dispersion studies are presented for the 77.0 mile reach of the Lehigh River from Francis E. Walter Lake to Easton, Pennsylvania. Rhodamine WT dye was injected at several points for a variety of several common flow conditions and its downstream travel was monitored at a number of downstream points by means of a fluorometer. Time-of-travel data have been related to stream discharge, distance along the river channel and dispersion. If 2.205 pounds of a conservative water soluble contaminant were accidentally spilled into the Lehigh River at Penn Haven Junction at Black Creek 6.09 miles downstream from Rockport, Pennsylvania, when the discharge at Walnutport, Pennsylvania, was 600 cubic feet per second, the leading edge, peak, and trailing edge of the contaminant would arrive 31.6 miles downstream at the Northhampton, Pennsylvania, water intakes 45, 54, and 66 hours later, respectively. The maximum concentration expected at the intakes would be about 1.450 micrograms per liter. From data and relations presented, time-of-travel and maximum concentration estimates can be made for any two points within the reach. (USGS)

BASE FLOW AND GROUND WATER IN UPPER SWEETWATER VALLEY, TENNESSEE,
Geological Survey, Nashville, TN. Water Resources Div.
R. D. Evaldi, and J. G. Lewis.
USGS Water-Resources Investigations Report 83-4068, 1983. 30 p, 18 Fig, 8 Tab, 14 Ref.

Descriptors: Water resources, *Karst, *Limestone, Solutioning, Solution cavities, Hydrology, Hydrogeology, Carbonate-rock hydrology, Well supplies, *Base flow, *Tennessee, Valley and Ridge Physiographic Province, Monroe County, McMinn County, Loudon County, Sweetwater Valley.

Base flow measurements showed interbasin transfer of water among sub-basins of upper Sweetwater Valley. In general, topographically higher subbasins have deficient surface outflow unless significant spring flow occurs in the basin. Topographically lower areas adjacent to the main channel of Sweetwater Creek generally have surplus flow. Major flow surpluses were associated with areas in which the majority of flow originated at a spring. Unusual outflow was related to geology to hypothesize a ground-water flow network. Areas of ground-water flow up-gradient of large springs were hypothesized as likely areas for significant ground-water reservoirs. A water budget study indicated that during dry years approximately three-fourths of the annual flow to Sweetwater Creek may be derived from ground-water sources. Streamflow records were analyzed to estimate the frequency of low-flow of Sweetwater Creek. (USGS)

TWO APPROACHES FOR ESTIMATION OF MANNING'S N IN MOUNTAIN STREAMS,
Wyoming Water Research Center, Laramie.
T. A. Wesche, W. T. Hill, and V. R. Hasfurther.
Available from the National Technical Information Service, Springfield, VA 22161, as PB84-154400, Price codes: A03 in paper copy, A01 in microfiche. Completion Report, September, 1983. 48 p, 17 Fig, 7 Tab, 14 Ref. Project No. OWRT A-030-WYO (2), Contract/Grant No. 14-34-0001-2154.

Descriptors: Natural streams, *Manning's Equation, *Roughness coefficient, Velocity, *Flow characteristics, Hydraulic models, Rocky Mountain region, Errors, Manning's n, Roughness (hydraulic).

An analysis of roughness coefficients for mountain streams in the Rocky Mountain Region was conducted to devise an empirical method for determination of Manning's n. Two approaches were developed. One procedure utilizes a diagrammatic key approach based upon water surface slope and observable channel characteristics, while the other attempts to relate the time-of-travel velocity of a dye cloud through a stream reach to channel roughness. The conclusions drawn indicate that good potential exists for the use of the diagrammatic key approach. A second significant conclusion of the study is that the estimation of n for steep, rough, tributaries at low flow by means of published tables and/or photographic comparisons can lead to erroneous results.

MAGNITUDE AND FREQUENCY OF FLOODS IN NEW JERSEY WITH EFFECTS OF URBANIZATION,
S. J. Stankowski.
Special Report 38, New Jersey Dept. of Environmental Protection, 1974. 46 p, 15 Fig, 7 Tab, 22 Ref.

Descriptors: *Flood peak, *Model studies, *Flood basins, *Flood recurrence interval, *Flood profiles, *Regional floods, Historic floods, Catchment areas, Maximum probable floods, Flood plain management, Mathematical models, Mathematical analysis, Floods.

This study developed an inexpensive and rapid method for estimating flood-peak magnitudes having recurrence intervals ranging up to 100 years for drainage basins larger than one square mile. The basins had various degrees of urban and suburban development. The method had to be applicable at open-channel sites on any nontidal New Jersey stream where flood flow is not significantly affected by upstream reservoir operation. Mathematical and graphical relations are presented to estimate flood-peak magnitudes; four parameters are required to use these relations. Three of these may be measured from topographic maps, i.e., basin size, channel slope, and surface storage within the basin. The fourth is an index of man-made impervious cover which can be determined for existing and future development conditions from census data and from readily available population projections. Developed from an analysis of flood information for 103 sites in New Jersey (the average period of record for the stations was 27 years), the relations should be useful for design of bridge waterway openings, selection of optimum size for drainage structures, evaluation of flood hazards for alternative land-use plans, and for definition of floodway and flood-hazard-area limits. Statewide averages indicate that urban and suburban development increases flood peaks up to three times at the 2-year recurrence interval and up to 1.8 times at the 100-year recurrence interval. (Garrison-Omniplan)
W84-03684

FLOODS OF AUGUST AND SEPTEMBER 1971 IN NEW JERSEY,
S. J. Stankowski.
Special Report, New Jersey Dept. of Environmental Protection, 1972. 204 p, 77 Fig, 9 Tab, 11 Ref, 1 Append.

Descriptors: *Historic floods, *Flash floods, *Storm water, *Rainstorms, *Precipitation, *Rainfall impact, Flood-plain management, Rainfall, Gaging stations, Flood peak, Rivers, Bridge design.

Floods of unprecedented magnitude in August 1971 created havoc in south-central, central and northeastern New Jersey. Then, record-breaking floods in September 1971 occurred in the highly urbanized basins of northeastern New Jersey. Total storm rainfall amounts in August during a 32-hour period ranged from about 3 to over 11 inches across New Jersey. River levels reached stages greater than any previously known in many areas of the state. The September flood averaged about 7 inches in northeastern New Jersey and caused recordbreaking peak flows in many streams. Detailed hydrologic data are provided on precipitation, stage and discharge for each gaging station during the period of storm runoff, flood stages and discharges, a comparison with the maximum floods previously known, and the estimated recurrence level. Flood-crest elevations are tabulated for more than 700 sites, in addition to the gaging stations. Flood profiles are shown for 36 streams. The stations at which new peak discharges were recorded had periods of record, in 1971, ranging from 1 to 51 years. New peak discharges were established at 17 stream-gaging stations with more than 30 years of record. The data presented may be used for planning and designing hydraulic structures and flood-protection works, for bridge and culvert design, for flood-plain management and flood insurance purposes, and for water-supply volume studies. HINDCASTING MONTHLY RUNOFF,
Michigan Univ., Ann Arbor. Dept. of Civil Engineering.
E. F. Brater, and R. Wallace.
Journal of Hydraulic Engineering, Vol. 110, No. 2, p 126-141, February, 1984. 7 Fig, 2 Tab, 9 Ref, 1 Append.

Descriptors: *Hindcasting, *Runoff, *Precipitation rate, Temperature, Rainfall-runoff relationships, Gaging, Hydrologic budget, History, Water loss, Water storage.

Research was carried out to develop relatively simple low cost procedures for estimating chronological monthly runoff for the historical period before a gaging station was installed on the river but during which precipitation and temperature records are available. The method also supplies estimates of runoff during periods of missing records. The procedures are based on the equation for the water budget of a drainage basin which shows runoff to be a function of precipitation, water losses, and the change in storage. It is shown that current and antecedent precipitation and temperature can be used as independant variables to account for the water loss and storage terms. The methods were tested by calibrating the models for the more recent years of records and then hindcasting runoff for earlier periods during which measured runoff was available for comparison. MEASUREMENT OF STREAMWISE VORTICITY FLUCTUATIONS IN A TURBULENT CHANNEL FLOW,
Max-Planck-Inst. fuer Stroemungsforschung, Goettingen (Germany, F.R.).
E. G. Kastrinakis, and H. Eckelmann.
Journal of Fluid Mechanics, Vol. 137, p 165-186, December, 1983. 23 Fig, 37 Ref.

Descriptors: *Channel flow, *Turbulent flow, Measuring instruments, Vorticity, Flow, Velocity, Streams.

Measurements of streamwise vorticity fluctuations have been made in a fully developed turbulent channel flow. A newly designed probe provided simultaneously in addition to the vorticity signal all three velocity signals. The new probe resembles the Kovasznay-type vorticity probe, but consists of four electrically independent hot wires, each mounted separately on a total of eight supporting prongs. A new calibration technique had to be developed for this probe. A strong increase of flatness factor with wall distance indicates a strongly intermittent character for the streamwise component of vorticity in this region. The flatness factor shows values similar to those for the three fluctuating velocity components only in the vicinity of the wall, where most streamwise vortices are observed. (Baker-IVI)

NEW NON-LINEAR CONCEPTUAL MODEL OF FLOOD WAVES,
Polish Academy of Sciences, Warsaw. Inst. of Geophysics.
J. J. Napiorkowski, and P. O'Kane.
Journal of Hydrology, Vol. 69, No. 1, p 43-58, February, 1984. 5 Fig, 13 Ref.

Descriptors: *Flood waves, *Model studies, St. Venant's model, Open channels, Hydrologic models, Simulation.

St. Venant's nonlinear distributed model of flood waves in open channels has been successfully simulated using a much simpler nonlinear lumped conceptual model. This simpler model is composed of a cascade of equal nonlinear storage elements preceded by an element of pure delay. The linear channel (a pure translatory system) reflects the time of propagation of a perturbation along the positive characteristic. The cascade of nonlinear reservoirs is responsible for the attenuation of the system response. The simpler model depends on four parameters only. The first two terms of the Taylor expansion of the state trajectory are shown to be equivalent to the first two terms of a Volterra convolution series. An example is offered to demonstrate the accuracy of this quadratic approximation. (Baker-IVI)

FLOOD ROUTING BY A LINEAR SYSTEMS ANALYSIS TECHNIQUE,
Ministry of Works and Development, Christchurch (New Zealand).
D. G. Goring.
Journal of Hydrology, Vol. 69, No. 1, p 59-76, February, 1984. 7 Fig, 4 Tab, 11 Ref.

Descriptors: *Flood routing, *Model studies, Linear programming, Systems analysis, Hydrologic models, River systems, Estimating, Forecasting.

There are two modes of flood routing: simulation and forecasting. A hydrological technique for flood routing using linear systems analysis has been presented and applied to a practical case both in the simulation and the forecasting mode. This method has particular application in river systems where the contribution from ungauged tributaries is significant. The method gives the peak flow within 12% accuracy in both modes in an example where only 57% of the total flow into the system was available for analysis. From a hydraulician's point of view, the main problem with a linear model for routing floods is that it may underestimate the wave speed. However, the linear systems method allows for this and the time of the flood peak usually is estimated within one time unit on either side of the actual time. (Baker-IVI)

TESTING PHYSICALLY-BASED FLOOD FORECASTING MODEL (TOPMODEL) FOR THREE U.K. CATCHMENTS,
Institute of Hydrology, Wallingford (England).
K. J. Beven, M. J. Kirkby, N. Schofield, and A. F. Tagg.
Journal of Hydrology, Vol. 69, No. 1-4, p 119-143, February, 1984. 13 Fig, 4 Tab, 23 Ref. N.E.R.C. grant GR3/2119.

Descriptors: *Flood forecasting, *Model studies, *Catchment areas, Crimple Beck, Hodge Beck, Wye headwater, Wales, Rainfall-runoff relationships, Rainfall, Evaporation, TOPMODEL, Model testing.

For many years, attempts at modelling the complex processes by which a basin converts rainfall to runoff were largely concerned with using lumped analogues. More recently, attention has concentrated on the 'contributing area' concept, so that is now accepted that the dynamic spatial variability of these runoff source areas must be treated more effectively. A previously developed model has been tested on three catchments: Crimple Beck (8 sq km) near Harrogate, Hodge Beck (36 sq km) on the North York Moors and the Wye headwater (10.5 sq km) in central Wales. The model was originally validated on subcatchments within Crimple Beck. For this study forecasts were made over a period of one year, based only on rainfall and evaporation data. The model parameters were derived from a defined program of field measurements over a period of 2-4 weeks, and no formal optimization procedures were carried out before comparing forecasts with the measured stream discharge record. As a result of the comparisons, the model is seen as a useful approach for ungauged catchments of up to 500 sq km in humid-temperature climates. (Murphy-IVI)

METHOD FOR THE DETERMINATION OF THE DISCHARGE-FREQUENCY RELATIONSHIP IN UNGAGED ARID GRAVEL STREAMS,
Geological Survey of Israel, Jerusalem.
A. B. Begin, and M. Inbar.
Journal of Hydrology, Vol. 69, No. 1-4, p 163-172, February, 1984. 5 Fig, 1 Tab, 6 Ref.

Descriptors: *Flows, *Model studies, *Stream discharge, Drainage basins, Stream beds, Negev, Israel, Arid regions, Geomorphology.

Significant statistical relationships were defined between shear stress exerted by flows of certain recurrence intervals on stream beds and grain-size distribution. Based on these relationships it is proposed to determine discharge-frequency curves in ungaged reaches of the arid Negev of Israel. Application of this method requires measurement of the hydraulic geometry of the desired reach and the grain size of some samples in it. The method was applied to the lower reach of Nahla Zin and the 50-and 100-yr peak discharges were estimated. The results agreed with an estimate based on an assessment of discharge per unit area in the same drainage basin. (Baker-IVI)

STOCHASTIC ANALYSIS OF HIGH FLOWS GENERATED BY MIXED PROCESSES,
Saskatchewan Univ., Saskatoon. Dept. of Geography.
P. R. Waylen, and M.-K. Woo.
Canadian Journal of Civil Engineering, Vol. 10, No. 4, p 639-648, December, 1983. 6 Fig, 4 Tab, 6 Ref.

Descriptors: *Stochastic hydrology, *High flows, *Flood flow, Model studies, Probabilistic process, Mathematical studies, Snowmelt, Rainfall, Floods, Prediction, British Columbia.

Concepts previously developed and tested to analyze floods generated by a single process have been extended so as to be applicable to high flows resulting from more than one hydrological process. The method described preserves a theoretical and physical basis. A subdivision of the nonhomogeneous high flow data on the grounds of clearly definable hydrological processes also tends to improve the prediction of flood probabilities. The procedures are easy to apply and investigation of flood characteristics at increasingly higher truncation levels supports the finding that a complete reanalysis of data is not necessary, thus simplifying the computational task when information pertaining to various flood levels is required. The methodology is applied to three basins in southwestern British Columbia that experience both snowmelt and rainfall generated floods. (Baker-IVI)

ROLE OF CURRENT VELOCITY IN STRUCTURING EELGRASS (ZOSTERA MARINA L.) MEADOWS,
Virginia Univ., Charlottesville. Dept. of Environmental Sciences.
M. S. Fonseca, J. C. Zieman, G. W. Thayer, and J. S. Fisher.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 4, p 367-380, October, 1983. 5 Fig, 3 Tab, 27 Ref. NSF, International Decade of Ocean Exploration, Seagrass Ecosystem Study grant OCE77-27051.

Descriptors: *Water currents, *Velocity, *Eelgrass, Sediment distribution, Equilibrium, Habitats.

Measurements of velocity profiles, bathymetry, and surface sediment characteristics across eelgrass (Zostera marina L.) meadows yielded information on community development processes and functional attributes of this ecosytem. Height/length ratios of the meadows were positively correlated with tidal current velocity. Low, medium, and high current regimes were separated by surface current velocities of approximately 50 and 90 cm/s. Z. marina can tolerate approximately 120-150 cm/sec current velocities in the areas studied. Per cent silt-clay and organic matter content of the surface sediments are negatively associated with shead velocity, suggesting that meadows in high current areas are sources while meadows in low current areas are sinks of autochthonous detritus. Current velocity maintains seagrass meadows at different equilibrium levels (relative climaxes). We theorize these different equilibrium levels provide unequal habitat utilization potentials for the associated faunal community. (Author's abstract)

MODELING RAPIDLY VARIED FLOW IN TAILWATERS,
Army Command and General Staff Coll., Fort Leavenworth, KS.
M. G. Ferrick, J. Bilmes, and S. E. Long.
Water Resources Research, Vol. 20, No. 2, p 271-289, February, 1984. 20 Fig, 19 Ref.

Descriptors: *Hydrologic models, *Tailwater, *Varied flow, Waves, Hydroelectric power, Physical properties, Mathematical models, Flow regimes.

An understanding of the downstream propagation of sharp-fronted, large-amplitude waves of relatively short period is important for describing rapidly varying flows in tailwaters of hydroelectric plants and following the breach of a dam. A numerical model of these waves was developed by first identifying the primary physical processes and then performing an analysis of the solution. A linear analysis of the dynamic open channel flow equations provides relationships describing flow wave advection, diffusion, and dispersion in rivers. A one-dimensional diffusion wave model modified for application to tailwaters simulates the important physical processes and is straightforward to apply. The 'modified equation' and von Neumann analyses provide insight into the effects of numerical parameters theta, delta x, and delta t upon stabiity and dissipative and dispersive behavior of the solution, but the Hirt analysis is found to yield incorrect phase relationships. The capability and accuracy of the model are enchanced when physical diffusion of a river wave is balanced by numerical diffusion in the model. Field studies were conducted in two greatly different tailwaters to assess our understanding of large-scale, rapidly varying flow waves. The accurate simulation of waves having wide-ranging amplitudes, shapes, periods, and base flows attests to the soundness of both the physical basis of the model and the numerical solution technique. These studies reveal that diffusion of short-period waves in natural, free-flowing rivers is signficiant and that inertia is negligible. (Murphy-IVI)

FLOOD ESTIMATES FOR UNGAGED STREAMS IN GLACIER AND YELLOWSTONE NATIONAL PARKS, MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
R. J. Omang, C. Parrett, and J. A. Hull.
USGS Water-Resources Investigations Report 83-4147, July, 198. 10 p, 2 Fig, 2 Tab, 4 Ref.

Descriptors: Water rights, Regression analysis, Estimating equations, Streamflow, Drainage area, Glacier National Park, Yellowstone National Park, Basin characteristics, *Montana.

Estimates of 100-year discharges were made at 59 sites in Glacier National Park and 21 sites in Yellowstone National Park to assist the National Park Services in quantifying stream inflow and outflow in the Parks. The estimates were made using regression equations previously developed for Montana. The resulting 100-year discharges are listed in tables; the discharges ranged from 260 to 53,200 cu ft/s in Glacier National Park and from 110 to 27,900 cu ft/s in Yellowstone National Park. (USGS)

FLOOD OF JUNE 15, 1981, IN GREAT BEND AND VICINITY, CENTRAL KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
R. W. Clement, and D. G. Johnson.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $1.50 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4123, 1982. 9 p, 2 Fig, 2 Tab, 1 Ref.

Descriptors: *Floods, Flood frequency, Precipitation excess, Flood damage, Indirect flood measurement, Great Bend, *Kansas.

Torrential precipitation, as much as 20 inches in 12 hours, resulted in unprecedented flooding on Dry Walnut Creek in southwestern Barton County, central Kansas. Runoff from the storm caused extensive flooding in the town of Great Bend on June 15, 1981. Estimates of total damages exceeded $42 million. Measurements of peak discharges made in the downstream part of the Dry Walnut Creek watershed were as much as 3 1/2 times the estimated magnitude of the 100-year flood and in some locations exceeded the maximum previously measured discharge for the area. (USGS)

MUDFLOW HAZARDS ALONG THE TOUTLE AND COWLITZ RIVERS FROM A HYPOTHETICAL FAILURE OF SPIRIT LAKE BLOCKAGE,
Geological Survey, Tacoma, WA. Water Resources Div.
C. H. Swift, III, and D. L. Kresch.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $19.75 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4125, 1983. 20 p, 15 Fig, 2 Ref.

Descriptors: *Mudflows, Dam failure, *Flood inundation maps, *Washington State, Spirit Lake, *Mount St. Helens, Toutle River, Cowlitz River.

The debris avalanche accompanying the May 18, 1980, eruption of Mount St. Helens, in southwestern Washington, buried the former outlet of Spirit Lake, located 5 miles north of the volcano, to a depth ranging to 500 feet. Since that time, Spirit Lake has had no natural outlet and its lake level and contents have increased significantly. Erosion at the crest of the debris dam on the surface of the blockage and recent studies of the blockage stratig-

raphy and soil properties showing that the effective crest elevation is lower than the surface crest have led to concern that the lake may someday breach through or spill over the top of the blockage. A study was made by the U.S. Geological Survey to determine the extent of inundation that might result downstream in the Toutle and Cowlitz Rivers if a hypothetical breach should occur and generate a mudflow flood of catastrophic proportions. A hypothetical breach of Spirit Lake produced a hypothetical mudflow hydrograph with a peak discharge of 2.65 million cu ft/s and a sediment concentration of 65 percent by volume at Camp Baker on the North Fork Toutle River. Elevations determined by the hydraulic routing of the mudflow were used to prepare inundation maps, indicating depths of inundation to be about 60 feet at Castle Rock and Lexington; 30-40 feet at Toutle, Toutle Lake at Silver Lake, Kelson, and Longview; and 15-20 feet at Toledo. Travel times for the peak elevation were estimated to be about 15 hours to Kid Valley on the North Fork Toutle River, 21 hours to Castle Rock, 22 hours to Toledo, and 23 hours to Kelso and Longview on the Cowlitz River. INSTABILITY OF HYPERCONCENTRATED FLOW,
Technical Univ. of Denmark, Lyngby. Inst. of Hydrodynamics and Hydraulic Engineering.
F. Engelund, and W. Zhaohui.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 219-233, March, 1984. 13 Fig, 1 Tab, 5 Ref.

Descriptors: *Hyperconcentrated flow, *Flow characteristics, Flow, Flow profiles, Hydrodynamics, Mathematical models, Flood control, Flood plain management, River flow, Yellow River, China.

Volume concentrations of sediment as high as 35% have been recorded in the Yellow River and 56% in its tributaries. Such hyperconcentrated flow behaves quite differently from ordinary sediment-laden flow. The instability of hyperconcentrated flow observed in nature is reproducible in laboratory flumes using suspensions of bentonite. Similar instabilities are observed in a much simpler hydraulic system consisting of a container feeding a closed conduit. The behavior of two different clay suspensions, kaoline and bentonite, was investigated and the rheological properties were measured in a rotating viscosimeter. These non-Newtonian fluids are close to Bingham fluids, but deviate for small deformation rates. The instability is associated with some specific rheological properties. A simple mathematical model explains why the bentonite suspension was unstable at small discharges and stable at sufficiently large discharges. The kaoline suspensions were always stable. The agreement between calculations and observations is encouraging. (Murphy-IVI)

SYNTHETIC STREAMFLOW FORECAST GENERATION,
Washington Univ., Seattle. Dept. of Civil Engineering.
D. P. Lettenmaier.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 277-289, March, 1984. 4 Fig, 14 Ref. OWRT grant B-080-WASH.

Descriptors: *Streamflow forecasting, Mathematical models, Simulation analysis, Optimum development plan, Algorithms, Skykomish River, Washington.

Simulation models have proven a durable and useful tool for the development of water resource system operating policies. One important component of any operating policy is streamflow forecasting. Incorporation of streamflow forecasts in a simulation model can be difficult because of the stochastic nature of forecasts and the range of forecast models in use. A forecast generation algorithm is developed which is applicable for any forecast model, and requires as input only the coefficient of prediction, a measure of forecast accuracy, and the first three moments of the forecast period flows. The algorithm uses a lag one Markov structure for forecast errors, where the correlation coefficient is a function of the forecast model coefficient of prediction. The generation algorithm is demonstrated for simulation of 7 and 120 day forecasts for the Skykomish River, Washington. (Author's abstract)

CYANAZINE LOSSES IN RUNOFF FROM NO-TILLAGE CORN IN 'LIVING' AND DEAD MULCHES VS. UNMULCHED, CONVENTIONAL TILLAGE,
Pennsylvania State Univ., University Park.
J. K. Hall, N. L. Hartwig, and L. D. Hoffman.
Journal of Environmental Quality, Vol. 13, No. 1, p 105-110, 1984. 8 Tab, 15 Ref.

Descriptors: *Cyanazine, *Agricultural runoff, *No-tillage, *Corn, Mulch, Tillage, Herbicides, Water pollution sources, Pennsylvania.

In recent years, significant increases in planting of no-tillage corn has stirred our interest in determining the impact of this tillage system and residue mulched soil surfaces in reducing both erosion and herbicide losses from sloping cropland. Reduction of herbicide losses is important, due to frequently increased use of herbicides in this type of land culture. Moreover, occasional reports claiming increased chloro-s-triazine herbicide contamination of surface waters from agricultural, nonpoint source pollution, targeted as excessive runoff from conventional- and even reduced-tillage-planted corn land, despite considerable data to the contrary, provided the impetus for further research in this area. Losses of cyanazine in runoff from untilled soil planted to corn (Zea mays L.) were compared with losses from conventionally planted corn on a 14% slope in the growing seasons of 1977 through 1979. The no-tillage systems consisted of corn planted into corn stover residue and into 'living mulches' of birdsfoot trefoil (Lotus corniculatus) and crownvetch (Coronilla varia L.). The no-tillage systems reduced runoff, erosion, and herbicide movement. For example, runoff from conventional tillage ranged from 5.5 to 22% of the runoff-producing rainfall. Soil loss from the same system ranged from 4.4 to 32.2 Mg/ha. On the other hand, runoff from the no-tillage systems ranged from 0.07 to 2.5% of the runoff-producing rainfall, while soil losses ranged from 0 to 1.1 Mg/ha. Transport of cyanazine in water runoff and entrained sediment from tilled areas totaled 257.0, 16.0, and 32.7 g/ha for the respective growing seasons, which represented 5.71, 0.73, and 1.48% of the amount applied yearly, 4.5 kg active ingredient (ai)/ha-1977; 2.2 kg ai/ha-1978, 1979. In the same years, cyanazine losses from no-tillage areas were 6.5-33.7 g/ha, 0.1-1.8 g/ha, and 1.6-3.3 g/ha at similarly applied rates. Collectively, these represented losses ranging from $<$ 0.01 to 0.75% of sprayed levels. Using conventional tillage as a reference treatment, untilled surfaces reduced runoff from 86.3 to 98.7%, soil losses from 96.7 to 100%, and cyanazine losses from 84.9 to 99.4% over the three growing seasons. In general, the 'living mulch' surfaces were more effective in retarding erosion than the corn stover residue surfaces. Corn grain yields were not significantly reduced by 'living mulches' when adequate legume suppression was obtained with herbicide treatments. (Murphy-IVI)

LONGITUDINAL DISPERSION IN A STREAM CALCULATED BY ONE DIMENSIONAL NUMERICAL MODEL,
Norsk Inst. for Vannforskning, Oslo.
T. Tjomsland.
Nordic Hydrology, Vol. 14, No. 1, p 41-46, 1983. 1 Fig, 1 Tab, 8 Ref.

Descriptors: *Stream flow, *Model studies, *Lena River, *Norway, Flow, Tracers, Solute transport, Path of pollutants.

Longitudinal dispersion is an important process relevant to pollution in natural water courses. In order to control contamination and predict levels of pollution in a strem the stream's capacity to transport and disperse must be known. A one-dimensional numerical model was used to simulate water stage and dispersion of matter in a 2-km reach of the river Lena, southeastern Norway. The mean gradient of the stream was about 1%. The bottom sediments consisted mainly of cobbles and gravel. The transport of the tracer was measured at four stations placed 0.3, 0.5, 1.2, and 2.5 km downstream from the injection point. Calculated results show quite good agreement with field measurements. (Baker-IVI)

DEVELOPMENT AND APPLICATION OF A STORAGE MODEL FOR RIVER FLOW FORECASTING,
Kobe Univ. (Japan). Dept. of Agricultural Engineering.
T. Hata, and M. G. Anderson.
Nordic Hydrology, Vol. 14, No. 3, p 139-154, 1983. 12 Fig, 1 Tab, 5 Ref.

Descriptors: *Model studies, *Rainfall-runoff relationships, Floods, Prediction, Flood control, River flow, River Avon, England, River Kako, Japan.

A lumped sequential river flow forecasting model was developed which is flexible in both temporal and spatial scales, thus allowing simulations to be undertaken for a wide range of practical purposes. The method has some advantages compared with the discrete runoff analysis or direct runoff analysis method. One such advantage is the direct information about the storage of water in a river basin just before a storm which has a big influence on a flood runoff. The change from long-term simulation to short-term simulation and vice versa is easy in the current procedure because of the use of the same model with the same parameters. The required data input is very low and is restricted to topographic data for only small segments of the entire catchment. The model is successfully applied to the River Avon in England and the River Kako in Japan. (Baker-IVI)

FURROW IRRIGATION RUNOFF: A LINEAR SYSTEMS APPROACH,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
S. Sritharan, W. Clyma, and E. V. Richardson.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 1, p 29-42, March, 1983. 11 Fig, 6 Tab, 13 Ref, 3 Append.

Descriptors: *Furrow irrigation, *Runoff, Flood routing, Routing, Model studies, Unit hydrographs, Uniformity coefficient, Input-output analysis.

Runoff models for freely draining surface irrigation systems are mainly useful for the design of reuse systems and surface drainage systems. When a linear flood routing approach is taken for furrow irrigation runoff, the problem of delay in system response is confronted. This was dealt with by a constant response-variable delay linear model, and the corresponding input-output relationship was derived. This relationship of Duhamel Integral type was discretized, and an unconstrained least squares minimization procedure was used for the system identification for a set of furrow irrigation field data. After identifying a suitable delay function, the developed unit hydrographs were used in the interfurrow and interirrigation modes. Surface effects produced by clods and other nonuniformities existing in the furrows can cause considerable variation in the runoff prediction from the measured value. Uniformity in surface conditions is necessary for the successful application of the unit runoff hydrograph concept to furrow runoff prediction. (Murphy-IVI)

CENTRAL KANSAS FLASH FLOODS OF JUNE 1981,
National Weather Service Forecast Office, Topeka, KS.
L. W. Schultz.

Bulletin of the American Meterological Society, Vol. 65, No. 3, p 228-234, March, 1984. 5 Fig, 2 Ref.

Descriptors: *Flash floods, *Storms, *Kansas, *Flood forecasting, Great Bend, Hoisington, Soil water, Forecasting.

Two severe flash floods in central Kansas during June of 1981 were unusual as they occurred close together in time and space, only 8 days and 16 km apart. Terrain was not an important contributing factor to either flood. Moist soil that resulted from the first storm was apparently a significant contributor to the second flood. Forecasters should be alert to antecedent soil conditions. The maximum rainfall during the Hoisington storm washout was 185 mm which under normal circumstances would not have caused flooding. However, 100-150 mm of precipitation had fallen during the Great Bend storm only 8 days earlier. When moist soil conditions exist, considerably less rainfall is needed to produce flash flooding. The first, the Great Bend storm, developed during the afternoon and continued into the night, suggesting that daytime heating played a key role in initiating the convection. The Hoisington storm was a nocturnal event and occurred in the cooler air north of a stationary front with convection resulting from the flow of moist unstable air over the frontal zone. The moisture content of the atmosphere was very high for each event. The Great Bend and Hoisington storms had the general characteristics of the synoptic and frontal type floods, respectively. MAGNITUDE AND MODELLING OF SNOWMELT RUNOFF IN THE CAIRNGORM MOUNTAINS, SCOTLAND,

Stirling Univ. (Scotland). Dept. of Environmental Science.
R. I. Ferguson.

Hydrological Sciences Journal, Vol. 29, No. 1, p 49-62, 1984. 6 Fig, 3 Tab, 14 Ref.

Descriptors: *Snowmelt, *Runoff, *Scotland, *Cairngorm Mountains, *River Feshie, Model studies, Streamflow, Seasonal variations, Precipitation, Snowpack.

The Feshie is a right-bank tributary of the Spey draining the western edge of the Cairngorm mountains in Scotland. Streamflow in the River Feshie (106 sq km) shows persistent diurnal oscillations from March to June. Runoff in the study area is dominated by snowmelt in the spring months, with persistent diurnal oscillations reaching on one occasion >40 mm/d of meltwater production averaged over the snow or 23 mm/d over a 106-sq km basin. Daily discharges during the melt season can successfully be simulated from crude meteorological data by a simple lumped temperature-index method with built-in snowpack depletion. The three hydrometeorological parameters appear adequately stable from one year to the next and the model is less sensitive to these than to initial snowpack extent and water-equivalent thickness, which may vary greatly from year to year, and to errors caused by inadequate precipitation data. (Baker-IVI)

REGIONAL RELATIONSHIPS BETWEEN BASIN SIZE AND RUNOFF CHARACTERISTICS,

Athens Univ. (Greece). Dept. of Civil Engineering.
M. Mimikou.

Hydrological Sciences Journal, Vol. 29, No. 1, p 63-73, 1984. 3 Fig, 2 Tab, 15 Ref.

Descriptors: *Runoff, *Drainage basins, Watersheds, Rainfall-runoff relationships, Model studies, Flood control, Storms, Greece.

The maximum observed flood flow, the maximum annual constant loss, the lag time and the unitgraph peak for a certain storm duration for basins in the western and northwestern regions of Greece are increasing power functions of basin size. These functions explain the variation in the analyzed runoff characteristics. The maximum observed floodflow, the maximum annual constant loss, the lag time and the unitgraph peak for a certain storm duration for these basins are increasing power functions of basin size. For both regions single relationships are derived for the lag time and the unitgraph peak, whereas for the observed floodflow and the maximum annual constant loss they vary regionally with the climatic conditions. Care is needed in transferring regional relationships, like the ones in this study outside the immediate range and location of their derivation as they may be regionally varying. The transferability of their parameter values is also doubtful. The derived regional relationships can be used in accurately predicting design flood flows, annual runoff yields and unitgraphs of various storm durations for ungauged basins in the regions studied, needed for the hydrological design of various water resources development systems. (Baker-IVI)

AREAL PREDICTION OF ANNUAL FLOODS GENERATED BY TWO DISTINCT PROCESSES,

McMaster Univ., Hamilton (Ontario). Dept. of Geography.
M.-K. Woo, and P. R. Waylen.

Hydrological Sciences Journal, Vol. 29, No. 1, p 75-88, 1984. 7 Fig, 2 Tab, 8 Ref.

Descriptors: *Floods, *Prediction, Flood frequency, Gumbel distribution, Drainage basins, Mathematical equations, Snowmelt, Rainfall.

The compounded Gumbel distribution provides a good description of flood frequency in areas where the annual peak flows are produced by both snowmelt and rainfall. The spatial variation of the flood generating processes can be represented by trend surfaces fitted to the compounded Gumbel parameters. A combination of the spatial interpolation of the parameter values from the trend surface equations and an expansion of a given equation provides a tool to establish the various probabilities of annual floods for ungauged basins. Two tests were performed to demonstrate the usefulness of the proposed technique. The compounded distribution can apply not only to snowmelt and rainfall induced annual floods, but equally well to handle situations where floods are attributable to distinctive types of rainstorms, such as frontal rain and thunderstorm showers. Where the spatial variation of the distribution parameters is statistically summarized by trend surfaces, the probability distribution of annual floods can be predicted for ungauged streams. Thus the proposed method is applicable to different climatic regions and is practical for deriving flood frequencies for poorly gauged or ungauged basins in many isolated areas of the world. SPATIAL VARIABILITY OF RUNOFF,

Agricultural Research Service, Columbia, MO. North Central Watershed Research Center.
A. T. Hjelmfelt, Jr., and R. E. Burwell.

Journal of Irrigation and Drainage Engineering, Vol. 110, No. 1, p 46-54, March, 1984. 6 Fig, 2 Tab, 10 Ref.

Descriptors: *Runoff, *Spatial variability, *Small watersheds, Simulation, Water retention, Model studies, Storm runoff, Variability, Confidence limits.

During the spring and summer of 1981, 40 adjacent runoff-erosion plots (each 27.4 x 3.2 m) were maintained in a fallow condition. Twenty-six rainfall events occurred that produced runoff during this period. The array of plots simulate an intensively sampled watershed of field size, so the results are analyzed to describe spatial variation of runoff and water retention. The coefficient of variation for individual events in which all plots exhibited runoff ranged from 0.65-0.07. Individual plots did not react consistently throughout the series of storms, but were seen to shift between producing more and less than the average volume of runoff. In the usual descriptions applied by current mathematical models of small watersheds, each plot was identical, so these results contribute to defining confidence limits that can be applied to model results, i.e., if a mathematical model were constructed that predicted the 40-plot mean for each event, and that model were compared with the observed values for any one plot, there would be differences between predicted and observed results. This study helps to establish the significance of that difference. (Moore-IVI)

PREDICTION OF PEAK FLOWS ON SMALL WATERSHEDS IN OREGON FOR USE IN CULVERT DESIGN,

Pacific Northwest Forest and Range Experiment Station, Juneau, AK. Forestry Sciences Lab.
A. J. Campbell, and R. C. Sidle.

Water Resources Bulletin, Vol. 20, No. 1, p 9-14, February, 1984. 1 Fig, 3 Tab, 16 Ref.

Descriptors: *Flood peak, *Small watersheds, *Culverts, *Oregon, Roads, Forests, Flood frequency, Design criteria, Catchment areas, Precipitation, Elevation.

Using data from 80 Oregon watersheds that ranged in size from 0.54 sq km to 27.45 sq km, equations were developed to predict peak flows for use in culvert design on forest roads. Oregon was divided into six physiographic regions based on previous studies of flood frequency. In each region, data on annual peak flow from gaging stations with more than 20 years of record were analyzed using four flood frequency distributions: type 1 extremal, two parameter-log normal, three parameter-log normal, and log-Pearson type III. The log-Pearson type III distribution was found to be suitable for use in all regions of the State, based on the chi-square goodness-of-fit-test. Flood magnitudes having recurrence intervals of 10, 25, 50, and 100 years were related to physical and climatic characteristics of drainage basins by multiple regression. Drainage basin size was the most important variable in explaining the variation of flood peaks in all regions. Mean basin elevation and mean annual precipitation were also significantly related to flood peaks in two regions of western Oregon. The standard error of the estimate for the regression relationships ranged from 26 to 84%. (Author's abstract)

EFFECTS OF A MOVING RAINSTORM ON DIRECT RUNOFF PROPERTIES,

Department of Agriculture, Lethbridge (alberta). Research Station.
N. Foroud, R. S. Broughton, and G. L. Austin.

Water Resources Bulletin, Vol. 20, No. 1, p 87-91, February, 1984. 5 Fig, 1 Tab, 7 Ref.

Descriptors: *Rainfall-runoff relationships, *Flood flow, *Rainstorms, Flood hydrographs, Simulation, Mathematical models, Flood peak, Velocity, Moving rainstorms, Channel velocity.

The effects of a moving rainstorm on flood runoff characteristics were investigated. A flood hydrograph simulation model called 'FH-Model' and a natural watershed were used. A hypothetical rainstorm of 50 years recurrence interval, 75 mm depth, and 4 hours duration was used to show the effects of velocity and direction of the moving rainstorm on the runoff characteristics. Compared with an equivalent stationary rainstorm (ESRS), the peak flow caused by a rainstorm moving in a downstream direction with a speed equal to channel velocity, V, was 27.5% higher and the peak flow caused by the same rainstorm moving in an upstream direction was 21.7% smaller. These percentages reduced to 10.5% and 8.6% for storms moving downstream and upstream, respectively, at three times the channel velocity, 3V. There were negligible differences in the time of peak, Tp, between runoff caused by storms moving downstream and runoff produced by ESRS. However, Tp for a storm moving upstream at V velocity was 82% higher than that produced by ESRS, but was reduced to 27% higher when the storm velocity was 3V. (Author's abstract)

January. The soil moisture content on the north-facing site exceeded that of all other sites. The south-facing lower site was the driest, while the south-facing upper site and the ridge top were intermediate and had similar moisture regimes. It was concluded that the moisture regime of the south-facing lower site was a joined effect of aspect and relatively high stoniness. (Author's abstract)

SMALL-SCALE HETEROGENEITY AND SOIL-MOISTURE VARIABILITY IN THE UNSATURATED ZONE,
Toronto Univ. (Ontario). Dept. of Geography.
A. G. Price, and B. O. Bauer.
Journal of Hydrology, Vol. 70, No. 1-4, p 277-293, 1984. 9 Fig, 1 Tab, 30 Ref.

Descriptors: *Aeration zone, *Soil water, *Soil texture, Percolation, Soil hydraulics.

Soil moisture content was measured at seven location within the unsaturated zone of an instrumented swale using a subsurface moisture probe with a gauge scalar. The bulk of the data is from a 5 m long transect of five access tubes. Readings were taken at 0.1 m depth intervals starting at 0.2 m and extending to 2.3 m below the ground surface. Great variability in soil-water content exists in a soil mass of only 5.0-m length and 2.5-m depth. Surface-water inputs from snowmelt and runoff are spatially homogeneous throughout the basin, but interact with heterogenous soil to generate great complexity. Water which initially percolates vertically is differentially impeded as a result of subtle textural changes in the soil, and is then preferentially retained in such zones of transition, causing large differences in soil-water content to occur. The scale of this vertical variability is of tenths of meters, while lateral variability of soil moisture reflects textural changes over a few meters. The observed influence of small-scale heterogeneity on soil-water content suggests that the conventional assumptions of isotropicity and homogeneity of the textural and hydraulic properties of porous media used in drainage basin and hillslope hydrological models need scrutiny, even for single stratigraphic units. SUBMERSIBLE PRESSURE OUTFLOW CELL FOR MEASUREMENT OF SOIL WATER RETENTION AND DIFFUSIVITY FROM 5 TO 95 DEGREES C,
Geological Survey, Menlo Park, CA.
J. Constantz, and W. N. Herkelrath.
Soil Science Society of America Journal, Vol. 48, No. 1, p 7-10, January-February, 1984. 3 Fig, 10 Ref.

Descriptors: *Pressure outflow cell, *Soil moisture retention, *Soil temperature, Soil water diffusivity, Hysteresis, Moisture content.

A technique was developed to measure water content in soil as a function of capillary pressure from 5 to 95 degrees C. To overcome problems encountered at high temperature, a modified Tempe pressure cell containing a soil sample is suspended in a constant-temperature water bath. The cell's porous plate is in direct contact with circulating bath water, thus eliminating the problem of entrapped air bubbles. A balance located above the water bath measures water content changes in the soil by weighing the entire pressure cell under water. The technique is designed to measure soil water retention characteristics and to make transient outflow estimates of the soil water diffusivity at temperatures from 5 to 95 degrees C. The technique was also used to determine the isobaric temperature dependence of water retention in soil. Results indicate that at constant capillary pressure, the relationship between moisture content and temperature is hysteretic. (Murphy-IVI)

SHAPE FACTORS FOR SEEPAGE INTO PITS,
Illinois Univ. at Urbana-Champaign. Agricultural Experiment Station.
C. W. Boast, and R. G. Langebartel.
Soil Science Society of America Journal, Vol. 48, No. 1, p 10-15, January-February, 1984. 3 Fig, 1 Tab, 17 Ref. Illinois Agric. Exp. Stn. project 15-0356.

Descriptors: *Shape factors, *Seepage, Seepage pits, Hydraulic conductivity, Water table, Auger hole, Soil water.

The Auger Hole method for measuring hydraulic conductivity of soil below a water table has generally been used with relatively thin auger holes. For cerain situations, however, especially for stony soils, the practicality of using broad, shallow pits has been explored. This technique is called the 'pit-bailing' method. In the field 'pit-bailing' method, saturated hydraulic conductivity below a water table is determined from the rate of rise of water in a pit. The relationship between the rate of rise and the soil hydraulic conductivity is expressed as a shape factor. Shape factors are presented here for pits with length/radius ratio ranging from 0 to 2, for pits ranging from empty to 0.9 full, and for impermeable-barrier and very permeable source lower boundary conditions at various distances below the pit. The calculated shape factors are extrapolated to the situation of a pit in an effectively infinitely deep uniform soil. Shape factors for pits of a given fullness with a source or a semi-infinite lower boundary condition are found to decrease and then increase as the length/radius ratio of the bit increases, reaching a minimum typically when this ratio is between 0.2 and 0.5 for the semi-infinite case. This trend is investigated to determine whether it is due to calculation errors for extreme geometries or is due to real phenomena. That the trend exists is found by examining analytical solutions to two situations - a pit fully penetrating to an impermeable barrier and a disk in semi-infinite space. (Murphy-IVI)

STATISTICAL ANALYSIS OF SALINITY AND TEXTURE EFFECTS ON SPATIAL VARIABILITY OF SOIL HYDRAULIC CONDUCTIVITY,
Agricultural Research Organization, Bet-Dagan (Israel). Div. of Soil Physics.
E. Bresler, G. Dagan, R. J. Wagenet, and A. Laufer.
Soil Science Society of America Journal, Vol. 48, No. 1, p 16-25, January-February, 1984. 3 Fig, 6 Tab, 27 Ref.

Descriptors: *Soil hydraulic conductivity, *Salinity, *Soil texture, Statistical analysis, Soil properties, Hydraulic conductivity, Soil saturation, Saline soils, Semivariogram, Covariogram, Multiple regression.

Managing water to optimize crop production is dependent on soil properties that affect the ability of the soil to trasmit water and salts. A statistical analysis that identifies the dominant factors responsible for the spatial variability of the saturated conductivity (Ks) in a selected field is presented. The variables are considered random functions of the space coordinates. Two types of stationarity are investigated: a constant mean and stationary variogram (stationarity of order 2) and trend of the means (nonstationarity of the mathematical expectation) with stationary covariances. Linear models of statistical dependence were used. Elimination of factors of minor importance was based on correlation analysis. Electrical conductivity (EC) and percent sand were the most important independent variables, whereas Ks, was the dependent variable. The analysis showed that soil salinity (EC) accounted for only 10 to 15% of the variability of Ks, texture (percent sand) explained 25 to 45% of the Ks variability, and 10 to 15% of the variability was explained by the interaction between salinity and texture. Various soil factors other than salinity and texture accounted for 30 to 50% of the variability in Ks. Semivariograms and covariograms of KsEC, and percent sand did not have a sill because of a significant horizontal linear trend. Calculations showed that the trend accounted for a about a half of the variability of the original data. Semivariograms and covarigrams of a new population of residuals after extracting the trend gave values of the sills equal to the variances. The integral scale of the residuals of Ks and percent sand was estimated to be about 15 to 20 m, whereas salinity (EC) did not display a spatial structure. The results can be generalized for other studies with different values of variances and covariances of soil salinity and soil texture. (Murphy-IVI)

ENHANCEMENT OF THERMAL WATER VAPOR DIFFUSION IN SOIL,
Washington State Univ., Pullman. Dept. of Agronomy and Soils.
A. Cass, G. S. Campbell, and T. L. Jones.
Soil Science Society of America Journal, Vol. 48, No. 1, p 25-32, January-February, 1984. 5 Fig, 3 Tab, 31 Ref. Dept. of Energy contract DE-AC06-76RL0 1830.

Descriptors: *Water vapor diffusion, *Water vapor, Temperature gradient, Thermal conductivity, Model studies, Evapotranspiration, Soil water, Soil properties, Soil Temperature, Moisture content, Mechanistic enhancement factor, Phenomenological enhancement factor, Nonisothermal diffusion.

Theories based on 'simple' adaptations of Fick's Law of diffusion do not adequately describe thermally induced flow except for extremely dry soils. An accurate description of thermally induced water vapor flow is needed to understand flow processes associated with evaporation from bare soil, groundwater recharge in the presence of deep geothermal gradients and heat loss from shallow aquifers used to store thermal energy. The enhancement of water vapor diffusion in soil resulting from a temperature gradient was determined using a transient state thermal conductivity measurement. A method was adapted for this study to allow measurement of the thermal conductivity as a function of temperature, water content, and pressure. The data allowed separation of thermal conductivity from thermally induced latent heat transport. Both the mechanistic enhancement factor eta of Philip and de Vries and the phenomenological enhancement factor beta of Cary are calculated from the slope of the relationship between thermal conductivity and reciprocal relative pressure. The enhancement factor, eta approaches 1 for dry soil and increases rapidly to values around 10 for a sand and a silt loam at water contents above half saturation and temperatures about 22 degrees C. At high water content and 3.5 degrees C, eta increased to 15. The inflection point water content for the eta vs. saturation curve was about twice as high in silt loam as in sand. Measurements conform well to the pattern predicted by a theoretical examination of enhancement factor behavior. Experimental results were also compared with two recent quantitative models of beta. These model predictions did not agree with measured values, nor did they conform to the theoretical limits of beta derived in this paper except at intermediate saturation and temperature values. EFFECT OF PH ON SATURATED HYDRAULIC CONDUCTIVITY AND SOIL DISPERSION,
Agricultural Research Service, Riverside, CA. Salinity Lab.
D. L. Suarez, J. D. Rhoades, R. Lavado, and C. M. Grieve.
Soil Science Society of America Journal, Vol. 48, No. 1, p 50-55, January-February, 1984. 4 Fig, 2 Tab, 20 Ref.

Descriptors: *Hydrogen ion concentration, *Hydraulic conductivity, *Soil dispersion, Soil saturation, Soil water, Soil dispersants, Sodium adsorption rate, Electrolytes.

The adverse effects of exchangeable sodium on soil hydraulic conductivity (K) are well known, but at present only sodicity and total electrolyte concentration are used in evaluating irrigation water suitability. In arid areas, high sodicity is often associated with high dissolved carbonate and thus high pH, but in human areas high sodicity may be associated with low pH. To evaluate the effect of pH (as an indepedent variable) on K, solutions with the same SAR and electrolyte level were prepared at pH 6, 7, 8, and 9. Saturated K values were determined at constant flux in columns packed at a bulk density of 1.5 Mg cu m. At pH 9, saturated K values were lower than at pH 6 for a montmorillonitic and a kaolinitic soil. For a vermiculitic soil with lower organic carbon and higher silt content, pH changes did not cause large K differences. Decreases in K were not reversible on application of waters with higher electrolyte levels. The results from the K experiments were generally consistent with optical transmission measurements of dispersion. Although anion adsorption was at or below detection limits and cation exchange capacity (CEC) was only slightly dependent on pH, differences in pH effects on K among soils are likely due to differences in quantities of variable-charge minerals are organic matter. DIVISION S-5-SOIL GENESIS, MORPHOLOGY, AND CLASSIFICATION, MOISTURE REGIMES AND MORPHOLOGICAL CHARACTERISTICS IN A HYDROSEQUENCE IN CENTRAL MASSACHUSETTS,
Massachusetts Univ., Amherst. Dept. of Plant and Soil Sciences.
E. W. Pickering, and P. L. M. Veneman.
Soil Science Society of America Journal, Vol. 48, No. 1, p 113-118, January-February, 1984. 4 Fig, 25 Ref.

Descriptors: *Soil mottling, *Soil classification, Soil saturation, Soil water, Soil properties, Soil temperature, Soil water table, Water table, Water table fluctuations.

Characterization of mottling phenomena frequently is a requisite for soil classification and soil survey interpretation. The absence, presence, and nature of mottles have become a key morphological feature for the inference of soil drainage conditions as it is often impractical to measure the soil moisture regime directly through long-term monitoring. Moisture regimes and associated soil mottling patterns were investigated over a 2-yr period in a Paxton-Ridgebury-Scarboro hydrosequence in central Massachusetts. Changes in physical conditions in these coarse-loamy fragipan soils were monitored with well points, tensiometers, soil temperature probes, and redox potential electrodes. Well-drained soils appeared uniformly brown, reflective of a generally strongly oxidized environment. They also showed the greatest seasonal fluctuations in soil temperature ranging from 0 to 23 degrees C. Matrix colors of highest chromas (6 or higher) occurred in the moderately well-drained (MWD) soils where reducing and oxidizing environments coexist within the profile at some time during the growing season. Prominent ferrans and albans in the 2Cx horizons of MWD soils were related to sustained groundwater levels, although higher water tables often occurred for periods too short or too cold for development of strongly reducing conditions. The characteristics grey streaking patterns of fragipans were best expressed in the 2Cx horizons of MWD soils and can be attributed to reducing environments during periods with soil temperature above biologic zero when conditions are wet but unsaturated. Significant translocation and leaching of iron occurred in the somewhat poorly drained soils, as evidenced by olive-grey matrix colors. Channel neoferrans and some neoalbans indicated that a reducing environment may persist within the B2 horizon long after it has become unsaturated. Lowest chroma colors in this hydrosequence was found in the very poorly drained soils where perennial conditions of saturation or near saturation exists up to the soil surface resulting in the strongest reducing environment and least fluctations in seasonal temperatures. ANALYSIS OF LONG-TERM WATER TABLE DEPTH RECORDS FROM A HYDROSEQUENCE OF SOILS IN CENTRAL OHIO,
Ohio State Univ., Columbus. Dept. of Agronomy.
T. M. Zobeck, and A. Ritchie, Jr.
Soil Science Society of American Journal, Vol. 48, No. 1, p 119-125, January-February, 1984. 5 Fig, 2 Tab, 21 Ref.

Descriptors: *Water table depth, *Soil water table, Groundwater, Groundwater level, Drainage, Ohio.

Water table depth is a dynamic soil feature that fluctuates greatly from year to year and throughout the year when measured in the same soil series as well as between soils of different series. Water table depths and precipitation were measured over a 10-yr period on four adjacent forested soils in central Ohio. The soils included a hydrosequence of well, moderately well, poorly, and very poorly drained fine-textured soils. Graphs describing the probability of observing water tables during consecutive 2-week (semi-monthly) intervals, by soil depth class, were compared with estimates reported on USDA-Soil Conservation Service forms SOIL-SOI-5 and a method proposed in the Soil Survey Manual. All soils had a probability of an observed water table within 50 cm of the soil surface. Water tables were observed in all soils, with the exception of the well drained soil, within 25 cm of the surface, 10% of the time or more, over a 12- or 14-week period in the late winter and spring. LIMNOLOGICAL STUDIES IN LAKE VILLARRICA. MORPHOMETRIC, PHYSICAL, CHEMICAL, PLANKTONICAL FACTORS AND PRIMARY PRODUCTIVITY,
Universidad Austral de Chile, Valdivia.
H. Campos, W. Steffen, C. Roman, L. Zuniga, and G. Aguero.
Archiv fur Hydrobiologie, Suppl. 65, No. 4, p 371-406, December, 1983. 15 Fig, 5 Tab, 40 Ref.

Descriptors: *Oligotrophic lakes, *Limnology, *Lake Villarrica, *Chile, Chemical analysis, Plankton, Primary productivity, Physical properties, Morphometry, Phytoplankton, Trancura River, Nutrients, Seasonal variation.

Lake Villarrica is located in a pre-andean mountain range at 230 m above sea level. The lake is oligotrophic, monomictic, and temperate with winter circulation and summer stratification. Its main physical and chemical parameters were studied during a year. The same data were simultaneously obtained in its principal affluent, the Trancura river, which is an important supplier of nutrients to the lake. The phytoplankton was analyzed qualitatively and quantitatively with its seasonal variations in the water column. The diatoms are dominant in autumn-winter, and the Myxophyceae and Chlorophyceae in spring-summer. The pattern of annual variation of phytoplanktonic density coincides with that of chlorophyll-a and primary productivity. The maximum productivity was registered in summer. The zooplankton was analyzed qualitatively and quantitatively with its seasonal variations that follow the pattern of the phytoplankton density. Lake Villarrica seems to maintain its oligotrophy because of its morphometric constitution, seasonal variation regulated mainly by the temperature, limited input of nutrients from its affluents, seasonal phytoplankton variation with different communities (spring and summer) responsible for the greater productivity, and variation of the zooplankton density according to the phytoplankton density. TEMPORAL VARIATION IN ALGAL BIOASSAYS OF WATER FROM TWO PRODUCTIVE LAKES,
Freshwater Biological Association, Windermere (England).
J. D. Box.
Archiv fur Hydrobiologie, Suppl. 67, No. 1, p 81-103, October, 1983. 6 Fig. 3 Tab, 59 Ref.

Descriptors: *Algal growth, *Bioassay, *Phosphorus, Dissolved organic matter, Iron, Microcystis, Blelham Tarn, Esthwaite Water, England.

Results of laboratory bioassays using Microcystis aeruginosa (Cyanophyta) carried out over a year on GF/C filtered water-samples from two productive lakes (Blelham Tarn and Esthwaite Water) in the English Lake District are presented. It was necessary to add EDTA or Fe(III)EDTA to demonstrate the phosphorus limitation which had been predicted from N:P ratios (atomic). The increased yield obtained at all times with added EDTA or FeEDTA suggested that iron was of major importance to the growth of the test alga. Unenriched and nutrient enriched water samples taken from both lakes during winter showed very low yields which may have been caused by the effects of trace metals. The ability of the water-samples from both lakes to support growth of the test alga was restored during the spring and a maximum yield was obtained during the summer when the ambient nutrient levels were low. It was not possible to separate the effects which the spring and summer phytoplankton populations could have had on the test alga - for instance, the stimulatory effect of the raised pH or the possible effects of the increased levels of dissolved organic material. BENTHIC ALGAE OF THE DANUBE IN THE NEIGHBOURHOOD OF VIENNA (DIE BENTHISCHEN ALGEN DER DONAU IM RAUM VON WIEN),
Biological Station, Lunz am See (Austria).
E. Kann.
Archiv fur Hydrobiologie, Suppl. 68, No. 1, p 15-36, October 1983. 3 Tab, 73 Ref.

Descriptors: *Benthos, *Algae, *Danube River, Vienna, Austria, Water pollution effects, Wastewater.

The benthic algal biocoenosis (except diatoms) of the Danube to be found on embankment boulders, boats, pontoons and plants in the area of Vienna are described, with special reference to the influences of ecological factors, particularly sewage. The embankment boulders of the Danube are conspicuously green, owing mainly to epilithic chlorophytes, especially Cladophora. Diatoms are numerous. Often these algae are covered by detritus and then their development is hampered. On boats and pontoons there is a green belt of near-surface living algae such as Ulothrix, Cladophora and others. As epiphytes on algae and mosses, Chamaesiphon incrustans and diatoms prevail. The influences of the combined ecological factors are not clear in every case. The chemical factors and pH cause an algal flora known partially also from limestone streams. Influence of temperature or current could not be found. A zonation of the flora by the different water levels (high and low water) is not conspicuous. Light gradients are important on the lateral faces of stones. Sewage-pipe inflows are marked by tufts of Sphaerotilus and by an increase of green algae, especially Cladophora. Because of the broad ecological valence of the algae, it is not possible to classify them into distinct saprobity levels. Compared with other parts of the Danube some common species are found among the filamentous green algae and certain blue-green algae; but there are also important differences. (Baker-IVI)

ECOLOGICAL STUDIES ON THE PERIPHYTON PRODUCTIVITY IN THE RIVER LOISACH (PRODUKTIONSBIOLOGISCHE UNTERSUCHUNGEN AN DER LOISACH ANHAND VON AUFWUCHSMESSUNGEN),
Bayerisches Landesamt fuer Wasserwirtschaft, Munich (Germany, F.R.).
B. Wachs.
Archiv fur Hydrobiologie, Suppl. 68, No. 1, p 77-99, October, 1983. 12 Fig, 7 Tab, 12 Ref.

Descriptors: *River Loisach, *Aquatic productivity, *Periphyton, River Isar, Lake Kochel, West Germany, Nutrients, Light intensity, Flow rate, Diatoms.

Periphyton was monitored regularly from 1979 to 1981 at three stations in the middle region of the River Loisach. The dominant periphyton species were identified: certain diatoms, Hydrurus foetidus, green and blue algae. A comparison of the averaged biomass with ecological conditions shows that in the outflow from the lake, production is two to three times greater than that in the river immediately above the lake. This maximum development of the periphyton biocoenosis is due to the high frequency of diatoms as well as to the stronger growth of the alga Hydrurus foetidus in the outflow. A clear seasonal preference was shown by the major species. The higher productivity in the lake outflow and the high fluctuations in the periphyton mass of this river region in contrast to those of the inflow are due mainly to physical factors, as the water of this river system is not below class II in quality. The most important ecofactors controlling periphyton development in the Loisach are the intensity of light and the rate of flow. (Baker-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; I. GENERAL CHARACTERISTICS OF 42 LAKES AND THEIR PHOSPHOROUS LOAD. STUDY OBJECTIVES AND SCOPE,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
Z. Kajak, and B. Zdanowski.
Ekologia Polska, Vol. 31, No. 2, p 239-256, 1983. 3 Tab, 27 Ref.

Descriptors: *Lakes, *Eutrophication, *Phosphorus, *Poland, Drainage basins, Dimictic lakes, Polymictic lakes, Trophic level, Ecosystems, Water pollution sources.

General information is provided on complex studies conducted on 42 lakes (23 dimictic and 19 polymictic lakes) which are representatives for the lakelands in north-eastern Poland. The main objective was the characteristic of trophic state and the purity of lakes and a quantitative analysis of the main ecosystem components as a basis for determining characteristics and indices for lakes of various trophic state; the functioning of lake ecosystems depending on trophic state, pollution, and degree of mixing; and the rate of trophic state changes by comparing with data from other periods. At the study site sandy-loamy soils of an average permeability dominated. On the basis of the surface area of the drainage basin, the type of soil utilization, and the data on the amount and kind of sewage, and data on phosphorus export from land, the phosphorus load to lakes was estimated. Phosphorus load and also total phosphorus and nitrogen concentration in epilimnion in summer correlated positively with the density of river net in the drainage basin and with the ratio of surface area of the drainage basin to the surface area and volume of the lake. In 28 lakes also examined 15-29 years ago the visibility decreased, mainly in dimictic lakes. In some lakes the oxygen deficits in the hypolimnion were greater. The greater percent of dimictic lakes, where changes were observed as compared with the state some years ago, was undoubtedly due to the fact that the trophic status of these lakes was and is lower on the average than that of polymictic lakes, and thus more sensitive to the increasing load and concentration of nutrients. (Baker-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; II. LAKE CATCHMENT AREAS - PHYSICO-GEOGRAPHICAL ENVIRONMENT. DESCRIPTION OF THE REGION AND 43 LAKES,
Warsaw Univ. (Poland). Inst. of Physical Geographic Sciences.
E. Bajkiewicz-Grabowska.
Ekologia Polska, Vol. 31, No. 2, p 257-286, 1983. 1 Fig, 8 Tab, 13 Ref.

Descriptors: *Lakes, *Limnology, *Poland, Nutrients, Precipitation, Lithology, Catchment areas, Climates, Drainage areas, Water pollution prevention, Soil, Land use, Geography.

A lake drainage area located in north-eastern Poland, mainly in the Masurian Lake District, was used to assess the effect of physico-geographical parameters on the removal and supply of nutrient matter to lakes. The annual precipitation totals range from 500 to 600 mm in this area of Poland, and only in the morainic-hill zone do they reach 600-700 mm. In assessing the effect of the catchment areas on the potential of nutrient matter supply to the lake several physico-geographical parameters of the catchment area were taken into account. These included some morphometric parameters such as the size of the catchment area directly included in the outflow, the average gradient of the catchment area, the river-network density, as well as the lithology, soil type and land use. Parameters relating the catchment area size to the size of the water body itself and to its water volume were also considered. The aggregate total of the characteristics made it possible to group the catchment areas into four classes which differ in their possibilities of removing matter, and in their rate of its supply to the water body. The classification indicates the parameters which to a medium and high degree affect the potential of nutrient matter supply. (Baker-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; III. CHEMISTRY OF THE WATER IN 41 LAKES,
Instytut Rybactwa Srodladowego, Olsztyn-Kortowo (Poland). Zaklad Hydrobiologii.
B. Zdanowski.
Ekologia Polska, Vol. 31, No. 2, p 287-308, 1983. 3 Fig, 2 Tab, 21 Ref.

Descriptors: *Lakes, *Trophic level, *Poland, Eutrophication, Stratification, Phosphorus, Nitrogen, Nutrients, Seasonal variation, Ammonia, Magnesium, Dimictic lakes, Polymictic lakes.

Water chemistry was studied in 41 lakes in the north-eastern region of Poland. In each of the two types, dimictic and polymictic lakes, three lake groups were distinguished, differing in the content of phosphorous in the epilimnion. A comparison of variations in the content of chemical components in water during the growing season in the mictic type and their trophic groups indicates that an increase of trophic state of the lakes studied is characterized by: an increase in spring and summer concentration of phosphates, total organic and dissolved and particulate organic phosphorus; a growth of total organic, dissolved organic and particulate organic nitrogen; an increase in the content of ammonia in the surface and near-bottom water layers in both mictic types in spring, and an increase in the content of ammonia in the surface and near-bottom water layers in polymictic lakes in summer; a growth of the concentration of nitrates in both layers of dimictic lakes in spring; an increase in the content of calcium, potassium, bicarbonates, water oxidability and electrolytical conductivity in both layers and mictic types in spring and summer; and a growth of the content of magnesium in dimictic lakes. A high trophic state of lakes under the influence of pollution is indicated by high levels of total phosphorus and total nitrogen, summer concentration of ammonia and nitrites in the surface water layers of polymictic lakes; high summer content of ammonia at the bottom of dimictic lakes; high content of calcium, potassium, sodium, chlorides, sulfates, and carbonates; a high level of oxidability and electrolytic conductivity of water, but lower percentages of calcium and bicarbonates, at higher percentage of sodium, potassium and chlorides in the ion balance; high summer and spring concentration of phosphates, as well as their percentage in total phosphorus in the epilimnion. ECOLOGICAL AND CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; IV. CHEMISTRY OF BOTTOM SEDIMENTS IN 37 LAKES,
Instytut Rybactwa Srodladowego, Olsztyn-Kortowo (Poland). Zaklad Hydrobiologii.
B. Zdanowski.
Ekologia Polska, Vol. 31, No. 2, p 309-331, 1983. 4 Fig, 2 Tab, 9 Ref.

Descriptors: *Lake sediments, *Trophic levels, *Poland Nitrogen, Phosphorus, Bottom sediments, Organic matter, Seasonal variation, Chemical analysis, Dimictic lakes, Polymictic lakes.

Concentrations of organic matter, total, organic and mineral phosphorus, and of organic nitrogen were compared for bottom sediments in 37 lakes in north-eastern Poland. Studies were carried out during spring circulation and during summer stagnation. In dimictic lakes, the content of total phosphorus and total nitrogen in the near-bottom water layer increased in spring and summer together with the rising trophic state of the lakes. In bottom sediments the highest levels of total, organic and mineral phosphorus, of organic nitrogen and organic matter were found in lakes with the highest and those with the lowest trophic state. In dimictic lakes characterized by a high trophic state, the summer content of total phosphorus in the sediments was higher than the spring content. In other dimictic lakes the content of total phosphorus in sediments was lower in summer than in spring. Organic nitrogen in sediments increased in the summer in some dimictic lakes but decreased in others. In polymictic lakes, in spring and summer the content of total phosphorus in the near-bottom water layer increased. The content of total and organic phosphorus in the sediments of most polymictic lakes decreased in the summer, relative to the spring on an average of 23 and 26%. The bottom sediments of polymictic lakes did not differ much in respect to the content of organic nitrogen in spring. The content of organic nitrogen in the sediments of some lakes increased in summer on an average by 15%, relative to the spring level, whereas in the majority of lakes it decreased in the same period on an average by 15%, relative to the spring level. ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; V. CHLOROPHYLL CONTENT AND VISIBILITY OF SECCHI'S DISC IN 46 LAKES,
Instytut Rybactwa Srodladowego, Olsztyn-Kortowo (Poland). Zaklad Hydrobiologii.
B. Zdanowski.
Ekologia Polska, Vol. 31, No. 2, p 333-351, 1983. 2 Fig, 2 Tab, 26 Ref.

Descriptors: *Lakes, *Trophic level, *Visibility, *Chlorophyll, *Poland, Seasonal variation, Dimictic lakes, Polymictic lakes, Phosphorus, Nitrogen, Silicates, Secchi disks, Bottom sediments.

The lakes under study varied in their morphology, trophic state and degree of anthropogenic impact. For spring, significant positive correlations were found between content of total phosphorus in the epilimnion and chlorophyll. No such correlation was noted with total nitrogen or silicates. In summer, highly significant positive correlations were noted between concentration of total phosphorus and content of chlorophyll and less significant positive correlation was noted between content of total nitrogen and chlorophyll. No correlation was found with silicates. For spring and summer, highly significant negative correlation

was found between concentrations of chlorophyll and the visibility of Secchi's disc. Changes in the average content of total phosphorus and total nitrogen in lakes of both mictic types and in both periods were accompanied by a decrease of the weight ratio of nitrogen to phosphorus. In spring and summer, visibility decreased as the trophic state increased mainly in the dimictic lakes, while in the polymictic lakes it was clearly higher in the group of lakes of the highest trophic state. These findings confirm the view that an increase in the content of total phosphorus in the epilimnion of polymictic lakes is the result of its inputs from bottom sediments, and to a lesser extent of higher summer concentration of chlorophyll and lower visibiliy in these lakes. ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; VI. THE PHYTOPLANKTON OF 43 LAKES,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
I. Spodniewska.
Ekologia Polska, Vol. 331, No. 2, p 353-381, 1983. 11 Tab, 13 Ref.

Descriptors: *Phytoplankton, *Lakes, *Trophic levels, *Poland, Biomass, Species diversity, Eutrophication, Dimictic lakes, Polymictic lakes.

The biomass and structure of spring and summer phytoplankton of 24 deep, dimictic lake and 19 shallow, polymictic lakes were analyzed. The differentiation of phytoplankton biomass in particular lakes was greater in summer than in spring, and greater in polymictic lakes than in dimictic ones. In spring, blooms were recorded in three dimictic lakes and in nine polymictic lakes. In summer, blooms were noted in 10 dimictic lakes and in 15 polymictic lakes. In spring the most intensive water blooms were noted in three polymictic lakes. All had total phosphorus concentrations above 100 micrograms/liter. Two were considerably polluted. In summer a phytoplankton biomass about 30 mg/liter was noted in 9 very fertile polymictic lakes. In spring the nanoplankton contributed considerably to the total biomass of algae, both in dimictic and polymictic lakes. In summer the contribution of nanoplankton to total phytoplankton biomass was smaller than in spring, especially low in the most fertile polymictic lakes. The blue-green algae dominated the plankton of more fertile lakes. Dinoflagellates dominated in less fertile dimictic lakes. (Baker-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; VII. VARIATIONS IN THE QUANTITATIVE AND QUALITATIVE STRUCTURE OF THE PELAGIC ZOOPLANKTON (ROTATORIA AND CRUSTACEA) IN 42 LAKES,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
A. Karabin.
Ekologia Polska, Vol. 31, No. 2, p 383-409, 1983. 6 Fig, 3 Tab, 32 Ref.

Descriptors: *Poland, *Trophic level, *Ecology, *Lakes, Eutrophication, Zooplankton, Rotatoria, Crustacea, Bioindicators, Water pollution effects.

First attempts to determine the relation between the trophic state of lakes and the zooplankton colonizing them have been based on a faunistic analysis, thus searching for a relation between the occurrence of a given species in the lake and the trophic state. The aim is to determine a comprehensive analysis of zooplankton structure (numbers, biomass, specific and group structure) and its changes together with increasing trophic state of lakes differing in morphometry and degree of pollution. Only changes in the numbers of Rotatoria are directly connected with the increasing trophic state in lakes. The biomass ratio of Cyclopoida and Cladocera increases at first with a trophic state increase, but tends to decrease again in extremely eutrophic lakes. Quantitative parameters of zooplankton structure undergo considerable fluctuations, independently of lake trophic state. (Murphy-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTHERN-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT; VIII. ROLE OF NUTRIENT REGENERATION BY PLANKTONIC ROTIFERS AND CRUSTACEANS IN 42 LAKES,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
J. Ejsmont-Karabin.
Ekologia Polska, Vol. 31, No. 2, p 411-427, 1983. 4 Fig, 1 Tab, 24 Ref.

Descriptors: *Trophic levels, *Poland, *Lakes, *Ecology, Rotifers, Crustaceans, Nutrient removal, Cycling nutrients, Phosphorus, Phosphorus removal, Nitrogen, Nitrogen removal, Regeneration, Zooplankton, Eutrophication.

Lake eutrophication is a process leading to an increased pool of nutrients contained in a lake. If not expelled from an ecosystem permanently, these nutrients are recycled within it. The recycling consisting of rapid continual changes of their chemical forms. Analyses have been carried out of the rate of phosphorus and nitrogen regeneration by the zooplankton of 42 lakes representing a trophic and morphometric gradient. In unpolluted lakes, regardless of the type of mixis, an increase in total-P concentration was accompanied by a rise in the rate of P and N regeneration by the zooplankton, a reduction of the turnover time of P and a decrease in the value of the N:P ratio in excretion products. In polluted lakes no significant relationship has been found between the pool of P in the water and the rate of regeneration, but a considerable increase was found in the turnover time of P. Directional changes in the rate of P and N regeneration by the zooplankton, as well as a reduction of the N:P ratio, following an increase in the nutrient content of water bodies may play a significant role in changes in the value of primary production in the course of eutrophication. The cause of differences in the reaction of polluted water bodies to changes in the total-P concentration suggests that being limited by factors other than the trophic conditions, the zooplankton of such water bodies are unable to efficiently mineralize excess P input. (Murphy-IVI)

Descriptors: *Dimictic lakes, *Polymictic lakes, *Water circulation, *Stagnant water, *Macrobenthos, Trophic level, Phosphorus, Poland, Ecology, Taxonomy.

During the spring circulation and summer stagnation the macrobenthos of 24 dimictic and 20 polymictic lakes has been investigated in order to estimate their trophic state and purity, and to analyze the main ecosystem components with regard to their significance as indicators of the trophic state. In the profundal of dimictic lakes in the density and biomass of macrobenthos (especially the burrowing forms) show a tendency to decrease when the trophic state increases. With the advancing trophic state and the increase in depth the benthic fauna has became less varied. This was followed by a significant negative correlation of Shannon's index of species diversity with the trophic state of lakes determined on the basis of Ptot concentration in the water of epilimnion. (Murphy-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT XI. MEIOBENTHOS AND NEAR-BOTTOM MEIOFAUNA IN 20 LAKES,
Warsaw Univ. (Poland). Dept. of Hydrobiology.
K. Prejs, and K. Papinska.
Ekologia Polska, Vol. 31, No. 2, p 477-493, 1983. 1 Fig, 8 Tab, 13 Ref.

Descriptors: *Dimictic lakes, *Trophic levels, *Meiobenthos, *Meiofauna, Lake eutrophication, Bottoms sedments, Crustaceans, Nematodes, Ecology, Poland.

The environmental changes occurring in the profundal are connected with eutrophication and result in the phenomenon of oxygen deficit in the hypolimnion maintained for gradually longer periods of time. This is reflective of the animals living there. Species that are sensitive to deteriorating oxygen conditions are replaced by more resistant forms. The objective is to determine the relationship between some regularities in the occurrence of meiofauna and the gradient of lake eutrophication. Composition, numbers, biomass and species differentiation of meiobenthos and meiofauna in near-bottom water were analyzed in 20 dimictic lakes of different gradient of eutrophication. The highest species diversity of near-bottom meiofauna, near-bottom Cyclopoida and Nematoda, was observed in lakes with the least advanced trophic state. The correlation between commonly used indices of the trophic state of lakes and the above mentioned meiofauna characteristics was significant. (Murphy-IVI)

ECOLOGICAL CHARACTERISTICS OF LAKES IN NORTH-EASTERN POLAND VERSUS THEIR TROPHIC GRADIENT XII. DEPENDENCE OF CHOSEN INDICES OF STRUCTURE AND FUNCTIONING OF ECOSYSTEMS ON TROPHIC STATUS AND MICTIC TYPE OF 42 LAKES,
Polish Academy of Sciences, Krakow. Zaklad Biologii Wod.
Z. Kajak.
Ekologia Polska, Vol. 31, No. 2, p 495-530, 1983. 4 Fig, 6 Tab, 22 Ref.

Descriptors: *Polymictic lakes, *Dimictic lakes, *Trophic level, Mixis, Ecosystems, Phosphorus, Phytoplankton, Biomass, Epilimnion, Zooplankton, Poland.

To compile the results of complex studies on 42 lakes representative for lakelands in north-eastern Poland it was necessary to include information on the characteristics of drainage basin, physical and chemical characteristics of lakes, phytoplankton, zooplankton and its role in phosphorus and nitrogen circulation, macrobenthos and meiobenthos. This allows a characterization of the structural and functional characters of their ecosystems according to their trophic status and mixis. Biomass of phytoplankton (mainly blue-green algae) and of rotifers increase to the highest phosphorus concentrations in polymictic lakes, and reach much higher values than in dimictic ones. As the trophic state (Measured by Ptot) increases the percentage of phosphate phosphorus in Ptot increases as well as total nitrogen concentration (while the N:P ratio decreases), chlorophyll concentration, biomass of phytoplankton and blue-green algae, the contribution of blue-green algae to phytoplankton biomass, efficiency of phosphorus utililzation by blue-green algae and of nitrogen phytoplankton, numbers and biomass of rotifers. But the number of crustaceans undergo very little changes. Polymictic lakes have a higher trophic state than dimictic ones, mainly because more nutrients are returned from the bottom sediments to the water. This increase is observed up to the highest phosphorus concentrations recorded, whereas in dimictic lakes the biomass becomes rather stable at mean concentrations. Thus the efficiency of phosphorus utilization by phytoplankton is better in polymictic lakes. Despite all the regularities connected with changes of total phosphorus concentration in epilimnion the scatter of values (around the mean) is very high for particular lakes. Not many species can be treated

as definite indicators of the trophic state. (Murphy-IVI)

HABITAT EXPLOITATION BY LARVAE OF AMPHIPSYCHE MERIDIANA (TRICHOPTERA: HYDROPSYCHIDAE) IN A JAVANESE LAKE OUTLET,
Newcastle upon Tyne Univ. (England). Dept. of Zoology.
P. J. Boon.
Freshwater Biology, Vol. 14, No. 1, p 1-12, February, 1984. 5 Fig, 2 Tab, 40 Ref.

Descriptors: *Dam screens, *Intake screens, *Trichopteran, *Population density, Population dynamics, Flow, Ecosystems, Insect behavior, Larvae, Tuntang River, Java.

Trichopteran populations below a dam on the River Tuntang (Central Java) and on intake screens above the dam consisted almost exclusively of Amphipsyche meridiana. Larvae on dam screens were in tightly packed aggregations, with greater densities in deeper water, and were predominantly fourth or fifth instars during the period of observation. Below the dam, 40% of larvae were in the first three instars. Larvae at the dam screens were heavier and yielded larger emerging adults which contained more eggs per female. Mean net mesh sizes of fifth instar larvae varied greatly from 34 X 26 micrometer to 125 X 106 micrometer with larger mesh size possibly being positively correlated with faster flow rates. The dinoflagellate Peridinium, commonly found in the guts of larvae below the dam, was virtually absent in dam screen larvae, possibly due to mesh size differences. The behavior of larvae in aggregations was observed in a laboratory flow channel. After experimental destruction of feeding nets, larvae immediately ingested silk prior to the construction of a new net. Nets were spun in a 'figure 8' fashion, and took between 11 and 30 min to complete. Stridulation between larvae occurred frequently and may be related to the defence of silk reserves within territories. (Murphy-IVI)

MACROINVERTEBRATE-HABITAT RELATIONSHIPS IN THE RIVER TEIFI CATCHMENT AND THE SIGNIFICANCE TO CONSERVATION,
Welsh Water Authority, Powys (Wales).
R. A. Jenkins, K. R. Wade, and E. Pugh.
Freshwater Biology, Vol. 14, No. 1, p 23-42, February, 1984. 4 Fig, 7 Tab, 24 Ref.

Descriptors: *Macroinvertebrates, *Teifi River, *Catchment areas, *Conservation, Population density, Regression analysis, Habitats, Altitude, River width, Hydrogen ion concentration, Resource value.

A macroinvertebrate survey of various habitats (e.g. riffles, pools, tree roots) at sixteen sites in the Teifi catchment in September 1981 yielded 217 taxa excluding Hydracarina and Chironomidae. Sites with the greatest number of habitats were generally rich in taxa and supported the highest number of 'rare' species, the latter generally being associated with vegetation. However, species were not generally restricted to particular habitats although ecdyonurid mayflies predominated in riffles and one leptocerid caddisfly was principally collected from tree roots. Four groups of taxa which characterized three habitat groups were established using classification procedures and it was concluded that three habitat types (eroding, depositing and vegetation) should be sampled to describe adequately the macroinvertebrate fauna at each site. Three attributes (species richness, species rarity and site uniqueness) were used to establish the conservational value of each site; in general, the main river and one lowland tributary were of highest conservational signficance. Multiple regression analyses were used to establish significant relationships between the three attributes and environmental features such as number of habitats, altitude, river width, pH and total hardness. Such relationships may facilitate a rapid assessment of resources value without expensive biological survey. (Author's abstract)

BIOLOGY OF THE CATFISH CHRYSICHTHYS AURATUS (GEOFFORY) IN THE MAN-MADE TIGA LAKE IN NORTHERN NIGERIA,
Bayero Univ., Kano (Nigeria). Dept. of Biological Sciences.
M. G. De L. Sturm.
Freshwater Biology, Vol. 14, No. 1, p 43-51, February, 1984. 5 Fig, 4 Tab, 22 Ref.

Descriptors: *Catfish, *Tiga Lake, *Nigeria, Biological properties, Fish behavior, Artificial lakes, Population dynamics, Spawning.

A study was made of the biology of Chrysichthys auratus, a bottom-feeding omnivore, in Tiga Lake, a man-made lake in Northern Nigeria. Ripe females were present from April to September, coinciding with the hot season and rise in water level. First spawning took place at age II in females. No ripe males were found, and this was attributed to their spatial separation. Absolute fecundity was related to length and ranged from 327 to 1466 in forty-six females. Hyaline rings on the centra of lumbar vertebrae were counted to age 235 fish. The first ring is laid down at the end of the second year, after which the rings were formed annually, probably during the breeding season. The fish live for up to 6 years. There is a good fit of the growth curve to the von Bertalanffy equation. Growth is slow and a smaller maximum size is attained in the lake than in rivers. (Murphy-IVI)

ATP AS A BIOMASS INDICATOR IN EIGHT NORTH ISLAND LAKES, NEW ZEALAND,
Ministry of Works and Development, Hamilton (New Zealand). Water and Soil Science Centre.
R. D. Pridmore, A. B. Cooper, and J. E. Hewitt.
Freshwater Biology, Vol. 14, No. 1, p 73-78, February, 1984. 2 Fig, 2 Tab, 22 Ref.

Descriptors: *Adenosine triphosphate, *Biomass, *Lakes, *New Zealand, Carbon, Surface water, Biological properties, Mathematical equations, Bioindicators.

The determination of microbial biomass is often an essential step in the understanding and quantification of biological processes in aquatic ecosystems. The relationship between microbial ATP and biomass-carbon in the near surface waters (0.5-5 m) of eight New Zealand lakes was studied to determine the constancy of the carbon:ATP ratio under natural growth conditions. Concentrations of microbial carbon were estimated indirectly from cell volume determinations. The carbon:ATP ratio remained reasonably constant (interquartile range 248-291, n = 50), except during periods of nitrogen/phosphorus deficiency when carbon:ATP ratios increased to values greater than 400. During periods of nitrogen/phosphorus sufficiency, corresponding estimates of microbial ATP and biomass-carbon were strongly correlated (r = 0.97, n = 47) and related by the equation carbon = (287 + or - 20) ATP-(22 + or - 41) where carbon and ATP are expressed in mg/cu m. From this relationship an average carbon:ATP ratio of 267 (SE = 5) was calculated. This ratio was not significantly affected by the relative proportions of bacterial and algal biomass in the surface water samples. However, because of the marked deviation of the carbon:ATP ratio during periods of nitrogen/phosphorus deficiency, the routine use of ATP as a biomass indicator is discouraged. (Murphy-IVI)

FRESH WATERS OF SHETLAND: PHYSICAL AND MORPHOMETRIC CHARACTERISTICS OF LOCHS,
Institute of Terrestrial Ecology, Edinburgh (Scotland).
D. G. George, and P. S. Maitland.
Freshwater Biology, Vol. 14, No. 1, p 95-107, February, 1984. 7 Fig, 5 Tab, 21 Ref.

Descriptors: *Fresh waters, *Shetland, *Physical properties, *Morphology, Lochs, Ecology, Climate, Geology, Retention time, Sedimentation, Scotland.

The Shetland Island group lies 150 km to the north of mainland Britain, and has recently been developed as a center for oil exploration and production activities in the northern North Sea. Surveys were intended to provide an information base for planning decisions related to industrial developments on the islands. Basic physical and morphometric data were taken for sixty-five lochs on the islands. The interrelations between loch dimensions are comparable to those recorded elsewhere in Scotland, but the smaller lochs on Shetland tend to be somewhat shallower, and the large lochs somewhat deeper than usual. The flat bottomed nature of the small peaty pools presumably reflects the topographical processes involved in the formation and erosion of blanket peat. The greater depth of the larger stony basins, however, implies that the rate of sediment accumulation is fairly low. The streams draining into the lochs are often rich in allochthonous material since strong winds and driving rain cause rapid soil erosion on exposed slopes when vegetation is sparse. The results of a multivariate analysis show that most of the physical variables measured in the field are closely correlated with easily measured map attributes. (Murphy-IVI)

DIGEST OF WATER QUALITY OF THREE CENTRAL ILLINOIS IMPOUNDMENTS,
Illinois State Water Survey, Peoria. Water Quality Section.
S. D. Lin, and R. L. Evans.
Transactions of the Illinois State Academy of Science, Vol. 76, No. 1 and 2, p 277-280, 1983. 1 Tab, 2 Ref.

Descriptors: *Water quality, *Illinois, *Impoundments, Canton Lake, Decatur Lake, Eureka Lake, Transparency, Water temperature, Dissolved oxygen, Turbidty, Hydrogen ion concentration, Alkalinity, Ammonia, Nitrogen compounds, Phosphorus compounds, Iron, Manganese, Sulfate, Chlorine demand, Chemical oxygen demand, Total organic carbon, Silica, Threshold odor number, Algae, Actinomycetes, Standard plate count.

Samples from Lakes Canton, Decatur, and Eureka were collected weekly for over 2 years and were analyzed for 22 parameters. These parameters are transparency, water temperature, dissolved oxygen (DO), turbidity, pH, alkalinity, hardness, ammonia and nitrate nitrogen, dissolved and total phosphorus, iron, manganese, sulfate, chlorine demand, chemical oxygen demand (COD), total organic carbon (TOC), silica, threshold odor number (TON), algae, standard plate count (SPC), and actinomycetes. The transparency in Lake Canton was generally greater than that in Lakes Eureka and Decatur. The temperature stratification barrier for L. Canton and L. Eureka occurred at 12 to 14 feet and 4 to 10 feet, respectively, for about six months every year from mid-April to mid-October. The thermal stratification of the lakes was not a barrier to the anaerobic zone penetrating the overlying waters. In general, except during the summer stagnation periods, hardness, COD, and TOC in all lakes did not change in water column. In L. Decatur concentrations of pH, alkalinity, nitrate, sulfate, chlorine demand, and silica did not change on the

vertical. At the surface and mid-depth of L. Canton and L. Eureka, the turbidity, alkalinity, nitrate nitrogen, and sulfate concentrations were not significantly different. The magnitude of taste and odor in the three lakes was found to be a seasonal function. Water temperature and sulfate concentrations in the three lakes were well within the IPCB limits. Most of the water quality parameters exhibited no seasonal or yearly variation. There was no correlation between parameters except for TON vs. nitrate, sulfate, manganese, and chlorine demand. Much of these inter-reactions are still unknown. Thus, modeling a complicated natural system should be discouraged until the nature and rates of interactions are better defined. (Murphy-IVI)

OCCURRENCE OF OECETIS INCONSPICUA (WALKER) IN AN ACID STRIP-MINE LAKE OF SOUTHERN ILLINOIS,
Southern Illinois Univ. at Carbondale. Dept. of Zoology.
S. Zullo, and N. Bates.
Transactions of the Illinois State Academy of Science, Vol. 76, No. 3 and 4, p 293-296, 1983. 2 Tab, 21 Ref.

Descriptors: *Trichoptera, *Strip mine lakes, *Acidic water, *Illinois, Hydrogen ion concentration, Species composition, Aquatic habitats.

This study reports for the first time the finding of Oecetis inconspicua (Walker) in an acid-strip mine lake of southern Illinois. The caddisfly larvae and pupae were found among Typha latfolia detritus in less than one meter of water. Chemical composition of the surrounding water is typically rich in dissolved ions. The pH is around 3.2. Total dissolved solids concentration approaches 2450 mg/l. Species identification is important in all studies, but perhaps it is even more important in studies in acid strip-mine lakes because habitat conditions are vital to the species able to survive there. (Murphy-IVI)

WORK ENERGY IN A FINAL-CUT STRIP MINE LAKE IN SOUTHERN ILLINOIS,
Southern Illinois Univ. at Carbondale. Dept. of Zoology.
M. J. Chimney.
Transactions of the Illinois State Academy of Science, Vol. 76, No. 1 and 2, p 297-303, 1983. 4 Tab, 20 Ref.

Descriptors: *Work energy, *Strip mine lake, *Illinois, Birgean Work, Schmidt Stability, Total Direct Work, Moroni's Big Lake, Mathematical studies.

Calculation of the work parameters provides useful comparative data on the lacustrine energy dynamics within a lake. The work parameters: Birgean Work (B), Schmidt Stability (S), and Total Direct Work (G), were calculated for a final-cut strip mine impoundment located in southern Illinois using density data compensated for 1) temperature (= uncorrected work parameters: B, S, G) and 2) temperature, pressure, and salinity (= corrected work parameters: B', S', G'). Maximum work energies ocurred after the summer solstice and were comparable to levels observed in similar holomictic lakes. In general, $B' < B$, $S' > S$, and $G' < G$; These differences were attributed mainly to salinity; pressure was less important. Corresponding corrected and uncorrected work parameters were highly correlated with, and at the same time statistically different from, each other. Only differences between B' and B were regarded as limnologically significant however. (Murphy-IVI)

WATER QUALITY OF SOMERVILLE LAKE, SOUTH-CENTRAL TEXAS,
Geological Survey, Austin, TX. Water Resources Div.
E. McPherson, and H. B. Mendieta.
USGS Water-Resources Investigations Report 82-4124, 1983. 88 p, 20 Fig, 17 Tab, 25 Ref.

Descriptors: *Water quality, Surface water, Dissolved oxygen, Iron, Manganese, Nitrogen, Phosphorus, Dissolved solids, Chloride, Sulfate, Hardness, *Texas, Somerville Lake.

Lake Somerville in south-central Texas has excellent water for municipal, industrial, and agricultural use. The total dissolved solids of the water averaged 220 milligrams per liter during a study from 1975-80. This shallow lake has a mean depth of 14 feet. The average annual inflow and discharge is greater than the volume of the lake. These two factors, along with wind action and the cooling of surface water during both summer and winter keep the lake well mixed and aerated. Even in summer the dissolved oxygen concentrations at the bottom of the lake usually were in excess of 50 percent of saturation. Dissolved iron concentrations are less than 50 micrograms per liter and dissolved manganese concentrations are under 40 micrograms per liter. These small concentrations are largely attributable to year-round oxygenated water. Homogeneous or near homogeneous concentrations of total phosphorus and inorganic nitrogen can occur at any time of the year throughout the lake. Dissolved chloride concentrations averaged 43 milligrams per liter and dissolved sulfate concentrations averaged 63 milligrams per liter. The total hardness of the water averaged about 110 milligrams per liter, placing it in the moderately hard classfication. (USGS)
W84-03583

WATER QUALITY OF LAKES FAITH, HOPE, CHARITY, AND LUCIEN, 1971-79, IN AN AREA OF RESIDENTIAL DEVELOPMENT AND HIGHWAY CONSTRUCTION AT MAITLAND, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
E. R. German.
USGS Water-Resources Investigations Report 82-51, 1983. 71 p, 18 Fig, 18 Tab, 14 Ref.

Descriptors: *Water quality, *Lakes, Runoff, Precipitation, *Florida, Orange County, Seminole County, Maitland.

Lakes Faith, Hope, and Charity were sampled from April 1971 to June 1979 to monitor water quality before, during, and after construction of Maitland Boulevard and the Interstate Highway 4 interchange. Lake Lucien was added to the study in April 1975. Chemical quality of the lakes varies little in comparison with surface runoff, bulk precipitation, and the water in the surficial aquifer. Surface runoff supplied about 19 percent of the direct inflow to the lakes and contributed a total of about 2,000 pounds, per acre of lake surface, of dissolved solids from April 1971 to June 1979, while bulk precipitation contributed about 1,170 pounds per acre. Water quality in the lakes changed during the study, generally for the better. However, an infestation of elodea (Hydrilla verticillata), whose growth is not associated with water quality, developed in Lake Hope near the end of the study and has interfered with recreational use of the lake. (USGS)

Descriptors: *Lake sediments, *Trophic level, Nutrients, Phosphorus, Carbon, Nitrogen, Chlorophyll, Transparency, Sedimentation, Lakes.

The relationship between lake type, as expressed by various trophic characteristics, and sediment type, as expressed by determinations of simple chemical data on nitrogen, phosphorus, carbon and loss on ignition was studied. A BPN-value (bioproduction number), defined by the slope coefficient of the regression line between N-content and IG-content of surficial sediments provides most accurate information about lake trophic level on the scale from oligotrophy to eutrophy, provided that more than 50% of the lake area has lower loss on ignition than 20%. The BPN-value cannot be used as an indicator of trophic level if the IG-content is predominantly higher than 30% in a lake. In the latter case the ratio IG/N can be used as a means to differentiate lake humic level. The BPN-value, which is determined from sediment samples providing an even spread throughout the lake surface, yields lake typical information, whereas C/N rations yield site specific information. A diagrammatic interpretation between lake trophic type and lake sediments was developed. (Baker-IVI)

EFFECT OF OXYGEN CONCENTRATION ON THE RATES OF DENITRATIFICATION AND DENITRITIFICATION IN THE SEDIMENTS OF AN EUTROPHIC LAKE,
Kyushu Univ., Fukuoka (Japan). Dept. of Chemical Engineering.
M. Nakajima, T. Hayamizu, and H. Nishimura.
Water Research, Vol. 18, No. 3, p 335-338, 1984. 5 Fig, 16 Ref.

Descriptors: *Denitritification, *Denitratification, *Lake sediments, *Eutrophic lakes, Oxygen demand, Sediments, Nitrates, Nitrites, Acetylene inhibition method.

The acetylene inhibition method was used during initial 1 hr incubation periods after preculture under complete anaerobic conditions to determine the effect of oxygen concentration on the rates of denitratification and denitritification for wide ranges of nitrate and nitrite concentrations. Sediment samples were collected for use from a highly eutrophic lake. A maximum denitratification rate of 4 micromol/hr was obtained under anaerobic conditions. The denitratification rate was a decreasing function of the oxygen concentration below 60 microM. About the same rate was noted for denitritification in the range below 30 microM oxygen. Beyond 30 microM oxygen, this rate dropped to half of the maximum, and remained almost constant until a critical oxygen concentration was obtained. The critical concentration above which denitritification was suppressed thoroughly, depended on nitrite concentration. The rates of denitritification and denitratification under anaerobic conditions increased approximately proportionally to the temperature between 5-30 C. The rate of denitritification was always higher than that of denitratification at each temperature under 160 microM nitrate or nitrite concentration. (Baker-IVI)

EXTERNAL BUDGETS FOR PHOSPHORUS, NITROGEN AND DISSOLVED ORGANIC CARBON FOR THE ACIDIFIED LAKE GARDSJON,
Uppsala Univ. (Sweden). Limnologiska Institutionen.
O. Broberg, and G. Persson.
Archiv fur Hydrobiologie, Vol. 99, No 2, p 160-175, January, 1984. 2 Fig, 5 Tab, 40 Ref.

Descriptors: *Limnology, *Oligotrophic lakes, *Nutrients, *Lake Gardsjon, Sweden, Phosphorus, Nitrogen, Dissolved solids, Acidification, Acid rain.

Lake Gardsjon is situated in an area with thin moraines and difficultly weathered rocks where

lakes have been acidified during recent decades due to acid rain. A residence time of water in the lake is 1.0 yr. Deposition on the lake surface is the largest source of phosphorus and nitrogen, but the surrounding land contributes most of the dissolved organic carbon (DOC) entering the lake. Precipitation in forested areas is further enriched in phosphorus and DOC during the passage through the canopy. Phosphorus is effectively trapped within the soil profile, probably through adsorbtion to aluminum and possibly to iron. Retention in Lake Gardsjon is low for phosphorus compared to mesotrophic and eutrophic lakes but may not largely differ from other oligotrophic lakes. DOC is effectively broken down or precipitated within the lake, causing a high transparency. The possible carrier function of humic substances for nitrogen and phosphorus is of less importance in this lake than in brownwater lakes. (Baker-IVI)

INVERTEBRATE FAUNA OF A SMALL CHALK STREAM IN BERKSHIRE, ENGLAND, AND THE EFFECT OF INTERMITTENT FLOW,
Freshwater Biological Association, Wareham (England). River Lab.
J. F. Wright, P. D. Hiley, D. A. Cooling, A. C. Cameron, and M. E. Wigham.
Archiv fur Hydrobiologie, Vol. 99, No. 2, p 176-199, January, 1984. 4 Fig, 3 Tab, 29 Ref.

Descriptors: *Intermittent streams, *Invertebrates, *England, *Winterbourne, Streams, Aquatic fauna, Stream flow, Species composition, Seasonal variation.

The invertebrate fauna of the Winterbourne, which has intermittent flow in its upper section, was examined for one year. An initial survey at 17 sites along the entire 8 km long stream in February was followed by a bimonthly survey at 10 downstream sites until December. The distribution of species was analyzed and related to the flow regime. A total of 233 taxa were recorded. Examination of the species lists for each site demonstrated a marked discontinuity in the distribution of many species around the perennial head. This feature was also highlighted using cluster analysis. Species which were restricted to either intermittent or perennial sites and which showed a high frequency of occurrence in the samples could therefore be of help in determining the location of the perennial head. A proposal that the fauna of temporary streams consists of three components (permanent stream species, facultative species and specialized species) was examined in light of the species reported for the intermittent sites in the Winterbourne. TRIBUTARIES AS MODIFIERS OF THE RIVER CONTINUUM CONCEPT: ANALYSIS BY POLAR ORDINATION AND REGRESSION MODELS,
Sam Houston State Univ., Huntsville, TX. Div. of Life Sciences.
D. A. Bruns, G.W. Minshall, C. E. Cushing, K. W. Cummins, and J. T. Brock.
Archiv fur Hydrobiologie, Vol. 99, No. 2, p 208-220, January, 1984. 3 Fig, 3 Tab, 11 Ref.

Descriptors: *Benthic environment, *Rivers, *Tributaries, River Continuum Concept, Particulate matter, Salmon River, Idaho.

Data was collected on functional groups and organic matter parameters at sampling sites of differing stream size above, within, and below tributaries of the Middle Fork of the Salmon River, Idaho to discern tributary effects upon river continuum relationships. The composition of functional groups and benthic and combined organic matter parameters varied as significant functions of link magnitude in regression analyses both with and without data from tributary-affected sampling sites. The composition of transport based on data without tributary effects also varied as a function of stream size, but with tributary-affected sites included in the analysis, a statistically significant pattern was not evident. Transport seems to be more susceptible to tributary alteration. Tributaries most strongly modified river continuum patterns in regard to gathering collectors, predators, periphyton, and transported ultra-fine particulate organic matter ranging in size from 0.45 to 52 micrometers. Small tributaries seemed to set community development forward along the river gradient and large tributaries tended to set it back. (Baker-IVI)

MIGRATION PATTERNS OF FIVE FISH SPECIES IN THE MURRAY-DARLING RIVER SYSTEM,
South Australia Dept. of Agriculture, Adelaide.
L. F. Reynolds.
Australian Journal of Marine and Freshwater Research, Vol. 34, No. 6, p 857-871, 1984. 3 Fig, 6 Tab, 21 Ref.

Descriptors: *Fish migration, *Rivers, *Murray River, *Darling River, Australia, South Australia, Migration, Population dynamics, Fish behavior, Carp, Catfish, Perch.

Of 14,333 fish tagged in a study carried out in the Murray River, South Australia from 1974 to 1978, 1276 were recaptured. Some golden perch moved extensively upstream, many moving more than 1000 km. The migration followed, and appeared to be triggered by, a rise in water level at the onset of major flooding. The upstream migrations, made only by mature fish, appear to be a reproduction strategy to ensure that the eggs are distributed downstream. Common carp, which lay adhesive, demersal eggs, did not migrate but made only random, short distance movements. While data on other species were fewer it appears that Murray cod and catfish, both of which have demersal eggs, show similar movement patterns to carp whereas silver perch, which lays buoyant eggs, is similar to golden perch. Since catfish and Murray cod maintain popultions without undergoing major upstream spawning migrations, it can be supposed that purely local events such as overfishing, pollution, destruction of spawning areas by river channelization and desnagging could seriously depress or even destroy local populations. ABUNDANCE, BIOMASS AND DIVERSITY OF BENTHIC MACRO-INVERTEBRATES IN A WESTERN CAPE RIVER, SOUTH AFRICA,
Cape Town Univ. (South Africa). Percy Fitzpatrick Inst. of African Ornithology.
J. M. King.
Transactions of the Royal Society of South Africa, Vol. 45, Part 1, p 11-34, August, 1983. 3 Fig, 7 Tab, 32 Ref.

Descriptors: *Rivers, *Biomass, *Environmental effects, *Water resources development, South Africa, Invertebrates, Macroinvertebrates, Benthic environment, Streams, Wastewater disposal, Stellenbosch, Eerste River.

The Eerste River, situated in southwestern Cape Province, South Africa, has its upper reaches in a stony substratum and can be divided into three physical/biotic zones: the Mountain Stream, Upper River, and Lower River zones. Faunal samples were collected at monthly intervals between March 1975 and April 1976, from eight stations along the river. Abundance and biomass generally increased downstream, but were low below a dam construction site due to blanketing effects of silt on the substratum. Seasonal changes in abundance and biomass of macro-invertebrates differed along the length of the river, because of the presence of dissimilar animal communities. Levels were always low in winter, and peaked in spring. Highest values in both were in the Lower River in summer, reflecting a build-up of organic pollutants there during times of low flow. Species diversity of the Ephemeroptera, which was felt to be representative of the diversity of the total macro-invertebrate fauna, decreased downstream. Major decreases in diversity could be correlated with major changes in the quality of the water: at a town and at a sewage-farm outfall. In the silt-laden waters below a dam construction site, the fleeting occurrence of individuals of several different ephemeropteran species resulted in a high diversity index. Composition of the fauna was typical of local rivers with mountain sources. (Baker-IVI)

MULTIPURPOSE RESERVOIR OPERATION; 1. MONTHLY MODEL FOR A SINGLE RESERVOIR,
California Univ., Davis. Dept. of Land, Air and Water Resources.
M. A. Marino, and B. Mohammadi.
Journal of Hydrology, Vol. 69, No. 1-4, p 1-14, February, 1984. 4 Fig, 3 Tab, 10 Ref. CSRS project CA-D-LAW-411H, OWRT project A-0880CAL, and WRC project UCAL-WRC-W-617.

Descriptors: *Multipurpose reservoirs, *Model studies, *Reservoir operation, Computers, Linear programming, Systems analysis, Reservoirs.

The monthly operational model of Becker and Yeh (Water Resour. Res., 10:1107-1112, 1974) which maximized energy output of a reservoir system has been extended to allow for maximization of both water and energy from the system. The model is a combination of LP (used for period-by-period) and DP (used for optimization over the entire operation period). At every stage of the DP, a series of LP's are solved. Since the contract levels of water and energy are usually based on conservative estimates of natural inflows, the system is likely to be capable of providing more than these contract levels. The efficiency of the algorithm is improved through the use of parametric LP (reduces computation time) and an iterative solution procedure (which reduces computation time and core-storage requirements). These efficiency measures allow the use of minicomputers, which are more suitable for frequent updating purposes because of their lower cost. The reservoir operation model can easily be adapted for use in multireservoir systems. The iterative solution procedure allows for consideration of more than two primary purposes with relatively low computation time. (Baker-IVI)

MULTIPURPOSE RESERVOIR OPERATION; 2. DAILY OPERATION OF A MULTIPLE RESERVOIR SYSTEM,
California Univ., Davis. Dept. of Land, Air and Water Resources.
B. Mohammadi, and M. A. Marino.
Journal of Hydrology, Vol. 69, No. 1-4, p 15-28, February, 1984. 2 Fig, 4 Tab, 16 Ref. CSRS project CA-D-LAW-4116-H, OWRT project A-088-CAL, WRC project UCAL-WRC-W-617.

Descriptors: *Multipurpose reservoirs, *Reservoir operation, Planning, Management, Computers, Systems analysis, Model studies, Energy, Shasta Reservoir, Folsom Reservoir, California.

Daily operation models often do not consider the multiobjective nature of a reservoir system. The majority of the available models require an initial guess of the operation policy. Although optimality can be reached, the execution time (and therefore the cost of running the model) depends on the initial solution. A daily operation model for maximization of monthly water and energy output from a system of two parallel reservoirs is presented. The model uses optimum monthly water and energy contract levels obtained from the monthly release policy. These contract levels are adjusted to allow for differences between the daily and monthly forecast of inflow. The model is developed using a minicomputer to provide an inexpensive tool for updating the system. The model is applied to the Shasta and Folsom reservoirs of the California Central Valley Project with computation time requirements of less than 2 min. (Baker-IVI)

ORGANIC AND INORGANIC SULFUR CONSTITUENTS OF THE SEDIMENTS IN THREE NEW YORK LAKES: EFFECT OF SITE, SEDIMENT DEPTH AND SEASON,
State Univ. of New York Coll. of Environmental Science and Forestry. Dept. of Environmental and Forest Biology.
M. J. Mitchell, D. H. Landers, D. F. Brodowski, G. B. Lawrence, and M. B. David.
Water, Air and Soil Pollution, Vol. 21, No. 1-4, p 231-245, January, 1984. 9 Fig, 2 Tab, 45 Ref.

Descriptors: *Organic sulfur, *Inorganic sulfur, *Sediments, *Lakes, Sediment distribution, Sulfur, Oligotrophic lakes, Mesotrophic lakes, Eutrophic lakes, Chemical properties, Deposition, Oneida Lake, South Lake, Deer Lake, New York.

Sulfur, an essential nutrient, is found in both organic and inorganic forms. In oxygenated water, sulfate is the most common form of inorganic S, while anoxic conditions permit formation of reduced inorganic spedies such as sulfides. Water and sediment parameters, with emphasis on S constituents, were compared among lakes (Oneida, South, Deer), seasons, sites and sediment depths. The three lakes differed in size, morphometry, productivity and acid neutralizing capacity and none of the lakes had anoxia in the water column. Redox potentials (Eh) were higher for oligotrophic south and mesotrophic Deer than eutrophic Oneida within the sediment. In the water column, the only S constituent measured was sulfate which was higher in nutrient rich Oneida (110 to 490 micromol/l) than South (30 to 70 micromol/l) or Deer (10 to 60 micromol/l). Total S in sediment was higher from South than for either Deer or Oneida. For Deer and South sediment, total S was greatest in the 5 to 15 cm layer, and this was likely due to historical changes in anthropogenic inputs through atmospheric deposition. The high S concentration in South sediment can be accounted for by particulate deposition of S through the water column. Organic S constituents constituted major forms of S in the sediments of the three lakes. Non-HI reducible S, of which carbon-bonded S was a dominant constituent, comprised a major portion of total S in Oneida, South and Deer. Ester sulfate was higher in Oneida than South or Deer. There was an inverse relationship between sediment Eh and sulfide. Pyritic S was measured on bulk samples and constituted 37, 12, and 6% of total S in Oneida, South and Deer. Both inorganic and organic S forms showed season variation and the transformation and translocation of these forms play an important role in the S dynamics of lakes. (Murphy-IVI)

DISTRIBUTION, ABUNDANCE AND CARBON ISOTOPIC COMPOSITION OF GASEOUS HYDROCARBONS IN BIG SODA LAKE, NEVADA: AN ALKALINE, MEROMICTIC LAKE,
Geological Survey, Menlo Park, CA.
R. S. Oremland, and D. J. Des Marais.
Geochimica et Cosmochimica Acta, Vol. 47, No. 12, p 2107-2114, December, 1983. 3 Fig, 3 Tab, 61 Ref.

Descriptors: *Big Soda Lake, *Nevada, *Alkaline water, Carbon, Meromictic lakes, *Hydrocarbons, Anoxic water, Bottom sediments, Gases, Ethylene, Propylene, Ethane, Propane, Isobutane, n-Butane, Methane, Water column, Sedimentology, Carbon radioisotopes, Mixolimnion.

Habitats favorable for the early, depositional stages of oil and gas formation probably include aquatic environments with permanently anoxic bottom waters whose sediments receive large inputs of organic matter from their productive surface waters. Only a few studies have characterized the low molecular weight gaseous hydrocarbons found within possible present-day analogues of such ancient anoxic, hypersaline environments. Distribution and isotopic composition (sigma C-13) of low molecular weight hydrocarbon gases were studied in Big Soda Lake (depth = 64 m), an alkaline, meromictic lake with permanently anoxic bottom waters. Methane increased with depth in the anoxic mixolimnion (depth = 20-35 m), reached uniform concentrations (55 microM/l) in the monimolimnion (35-64 m) and again increased with depth in monimolimnion bottom sediments (> 400 microM/kg below 1 m sub-bottom depth). The sigma C-13(CH4) values in bottom sediment below 1 m sub-bottom depth (< -70 per mil) increased with vertical distance up the core (sigma C-13(CH4) = -55 per mil at sediment surface). Monimolimnion C-13(CH4) values (-55 to -61 per mil) were greater than most sigma C-13(CH4) values found in the anoxic mixolimnion (92% of samples had sigma C-13(CH4) values between -20 and -48 per mil). No significant concentrations of ethylene or propylene were found in the lake. However ethane, propane, isobutane and n-butane concentrations all increased with water column depth, with respective maximum concentrations of 260, 80, 23 and 22 nM/l encountered between 50-60 m depth. Concentrations of ethane, propane and butanes decreased with depth in the bottom sediments. Ratios of CH4/(C2H6 + C3H8) were high (250-620) in the anoxic mixolimnion, decrease to approximately 161 in the monimolimnion and increased with depth in the sediment to values as high as 1736. We concluded that methane has a biogenic origin in both the sediments and the anoxic water column and that C2-C4 alkanes have biogenic origins in the monimolimnion water and shallow sediments. The changes observed in sigma C-13(CH4) and CH4/(C2H6 + C3H8) with depth in the water column and sediments are probably caused by bacterial processes. These might include anaerobic methane oxidation and different rates of methanogenesis and C2 to C4 alkane production by microorganisms. (Murphy-IVI)

NITROGEN BUDGET FOR A SMALL CONIFEROUS FOREST STREAM,
Geological Survey, Menlo Park, CA. Water Resources Div.
F. J. Triska, J. R. Sedell, K. Cromack, Jr., S. V. Gregory, and F. M. McCorison.
Ecological Monographs, Vol 54, No. 1, p 119-140, March, 1984. 3 Fig, 9 Tab, 106 Ref. NSF grants DEB 74-20744A02 and DEB 767-21402.

Descriptors: *Nitrogen budget, *Streams, Nitrogen cycle, Nitrogen, Nitrogen fixation, Allochthonous, Cycling nutrients, Oregon.

Small streams draining heavily forested watersheds depend on organic inputs from the adjacent terrestrial environment (Allochthonous) as a source of fixed carbon and nutrients for in situ biological processes. An annual nitrogen budget is presented for a small stream draining Watershed, 10, H. J. Andrews Experimental Forest, Oregon. The role of allochthonous debris in the input, flux, and export of nitrogen is emphasized in the material balance budget. All material entering the stream channel was presumed to enter the water sometime during the year. Material estimates are based on total channel area. The major annual nitrogen input (1974-1975) was subsurface flow (11.06 g/sq m) as dissolved organic nitrogen (10.56 g/sq m) and nitrate (0.05 g/sq m). Biological inputs of nitrogen amounted to 4.19 g/sq m as direct terrestrial inputs of: litterfall (1.35 g/sq m), laterial movement (1.78 g/sq m), and throughfall (0.30 g/sq m). Nitrogen fixation on fine wood debris contributed an additional 0.76 g/sq m based on rates from a nearby watershed. Total nitrogen input was 15.25 g/sq m. The nitrogen pool was dominated by large amounts of particulate organic matter. Coarse wood constituted 32% of the nitrogen pool (3.80 g/sq m) and fine wood fractions 18% (2.18 g/sq m). The coarse wood fraction greatly influenced stream morphology. Fine organic particulates constituted an additional 40% of the nitrogen pool (4.77 g/sq m). DON (dissolved organic nitrogen) export (8.38 g/sq m) was less than input, presumably due to biological uptake associated with litter mineralization, sorption, and chemical flocculation. Due to effective retention of particulate inputs by debris dams, biological processing in the particulate nitrogen pool, and uptake and sorption of DON, most particulate organic inputs increased in nitrogen concentration prior to export. Particulate organic nitrogen input (3.13 g/sq m) was greater than export (2.53 g/sq m). Total annual nitrogen output was 11.36 g/sq m, resulting in a gain of 3.89 g/sq m/yr to the stream. Thus, the stream was not operating on an annual steady state, but on an input-output regime related to the processing of refractory wood debris and resetting by major storms. Although particulate and dissolved nitrogen loss per hectare was small for the 10-ha watershed, these losses passed through or were accumulated in a pool encompassing < 1% of the watershed area. This concentration of N in the stream allowed establishment of a separate ecosystem whose processing efficiency and capabilities for nutrient cycling were related to the retention capacity of the channel and nutrient quality of inputs within the reach. FISH ASSEMBLAGES IN A RIVER WITH UNUSUAL GRADIENT (LUONGO, AFRICA - ZAIRE SYSTEM), REFLECTIONS ON RIVER ZONATION, AND DESCRIPTION OF ANOTHER NEW SPECIES,
Guelph Univ. (Ontario). Dept. of Zoology.
E. K. Balon, and D. J. Stewart.
Environmental Biology of Fishes, Vol. 9, No. 3/4, p 225-252, 1983. 14 Fig, 5 Tab, 92 Ref.

Descriptors: *Rivers, *Fish, *Luongo River, Africa, Zaire System, Zones, Species diversity, Topography, Drainage basins, Spatial distribution.

Fish distribution was studied in a river with an unusual gradient within the drainage system of Zaire headwaters. The Luongo River has high gradient upper and lower sections, separated by a long middle section of no gradients, and bordered by rapids and waterfalls. On the basis of Luongo's hydrographic history, topography and fish taxocenes, the river is divided into saltatory zones, each one inhabited by separate homeostatic fish communities. The problem of river natural zonation is argued. Luongo River is also unique for its high richness containing 49 species, its biogeographical correlations, and the number of undescribed species found (14%). One of these previously undescribed species, Chetia mola, is discussed. The probable reasons for the richness and for the discontinuous fish assemblages are discussed. (Baker-IVI)

INFLUENCE OF CERTAIN ENVIRONMENTAL FACTORS ON THE PREDATORY EFFICIENCY OF THE LARVIVOROUS FISH MACROPODUS CUPANUS,
Kerala Univ., Trivandrum (India). Dept. of Aquatic Biology and Fisheries.
S. S. Jacob, N. B. Nair, and N. K. Balasubramanian.
Environmental Biology of Fishes, Vol. 9, No. 3/4, p 295-300, 1983. 4 Fig, 4 Tab, 29 Ref.

Descriptors: *Fish behavior, *Predation, Feeding rates, Alternative planning, Mosquitoes, Biocontrol, Fish diets, Fish food organisms.

Investigations of the effect of certain environmental factors on predatory efficiency of the indigenous larvivorous fish Macropodus cupanus indicates the dependence, in a quantifiable way, of predation on the environmental complex surrounding the prey-predator system. Prey consumption is less at low temperatures and increases significantly with rise in temperature. Feeding under conditions of light is significantly higher than in darkness. Salinities of up to 21.83% do not affect predation rate, except that owing to stress conditions, prey intake at 21.83% is lower than at 0.12%. Consider-

ing fish size, in terms of unit body weight, predation declines significantly as size increases. However, when total body weight is considered, predation increases with increase in fish size. Environmental factors do not alter the time course of predation regularly or significantly, perhaps owing to haphazard intake subsequent to satiation and/or a 'learning' factor. The higher predation rate of this fish when compared to the conventional larvivore Gambusia affinis indicates its potential as a biocontrol agent of mosquito larvae. (Author's abstract)

CHARACTERISTICS OF A GENERAL MATHEMATICAL MODEL OF WATER-QUALITY MANAGEMENT IN LARGE RESERVOIRS,
Yu. S. Vasil'ev, G. V. Simakov, and A.I. Al'khimenko.
Hydrotechnical Construction, Vol. 17, No. 8, p 432-434, August, 1983. 4 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 8, p 36-37, August, 1983.

Descriptors: *Water quality, *Reservoirs, *Mathematical models, Stochastic process, Reservoir management, Water quality control, Prediction.

A model is sought which will permit predicting the water quality of a reservoir as a function of the concentration of pollutants in the water body both in space and in time. The synthesis of analytical solutions to the problem with results obtained from both prototype and laboratory experimental investigations is the most promising when constructing a general mathematical model of water quality management. It is expedient to compare the existing particular mathematical models oriented towards third- and fourth-generation computers. The occurrence of wind and its parameters must be considered as random variables. Wave parameters are also random variables. It is natural thus that the distribution of pollutant concentrations should be evaluated on the basis of a stochastic approach. In turn the refined mathematical model will make it possible to establish operating regimes of outlets corresponding to reality and to use more completely the self-purifying capacity of a water body. NITROGEN LOSS FROM FRESHWATER AND SALINE ESTUARINE SEDIMENTS,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
C. J. Smith, and R. D. De Laune.
Journal of Environmental Quality, Vol. 12, No. 4, p 514-518, 1983. 4 Fig, 1 Tab, 25 Ref.

Descriptors: *Denitrification, *Estuaries, *Sediments, Nitrification, Nitrogen cycle, Nitrogen balance, Nitrogen compounds, Chemical properties.

The predominant inorganic N species present in estuarine sediments is NH4(+). This ion is stable under anaerobic conditions, but in environments that have both aerobic and anaerobic zones, NH4(+)-N can be lost. The magnitude of ammonium-N (NH4+-N) loss from nitrification-denitrification reactions in bottom sediments collected from saline and freshwater Louisiana Gulf Coast lakes was determined. Studies were collected in the laboratory and field. Maximum gaseous N accumulation, from fresh-water and saline sediment amended with 4.5 microg nitrate-N (NO3(-)N)/g (on dry-wt basis), was 1.6 and 1.4 microg N/g, respectively. The addition of 50 microg NH4(+)-N/g stimulated the evolution of N2O from both sediments, and represents 0.02 and 0.2% of the NH4(+)-N applied to the saline and fresh sediment, respectively. Nitrous oxide (N2O) emissions measured in the field were low. The annual N2O emission was 10 and 34 mg N/sq m from the saline and freshwater lakes. These values agree closely with the N2O emission rates calculated from laboratory data. Denitrification was also estimated from NH4(+)-N amended sediment using the acetylene (C2H2) inhibition technique and N-15 balance. Recovery of N-15 decreased rapidly during the 0- to 8-week period when high denitrification rates were measured. The denitrification rate estimated from N-15 recovery during the 0- to 8-week period was 3.7 mg N/sq m/d for each sediment. Approximately 50% of the added N-15 was lost, an amount equivalent to 1.4 g N/sq m/y. As the added N-15H4(+)-N was incorporated into the organic N pool, little or no further N-15 was lost. FATE OF OXYGEN AND REFRACTORY ORGANICS IN MARMOT BASIN STREAMS: SEASONAL VARIATIONS,
Inland Waters Directorate, Ottawa (Ontario).
S. A. Telang, and G. W. Hodgson.
Journal of Environmental Quality, Vol. 12, No. 4, p 575-579, 1983. 1 Fig, 6 Tab, 13 Ref.

Descriptors: *Oxygen, *Organic compounds, *Marmot Basin, Total organic carbon, Chemical oxygen demand, Biological oxygen demand, Dissolved oxygen, Fulvic acids, Humic acids, Tannins, Lignins, Stream degradation, Alberta, Canada.

A conceptual process reactor model with input-output functions developed for the mountain streams of the Marmot Basin (Alberta, Canada) showed seasonal trends in the conversion of organic matter. Based on mass balance data, organic compounds (e.g., tannins and lignins), and total organic C showed net gains in the stream waters in winter; in spring, the compounds tend to be depleted in waters; in the fall, humics and tannins and lignins underwent net depletion. The indicated changes of accumulation and depletion ranged from +95 to -42% of incoming mass. The chemical O2 demand showed gains in the stream waters throughout the season. The biological O2 demand showed little change throughout the seasons. Photochemical processes appeared to be important processes in the conversion of organic matter in clear, cold mountain streams of the Marmot Basin. Biological uptake of refractory compounds appeared to be a minor process. (Author's abstract)

ECOLOGICAL SEASONAL CYCLES IN A COLORADO MOUNTAIN POND,
Colorado Univ. at Boulder. Dept. of Environmental, Population, and Organismic Biology.
P. M. Ellsworth.
Journal of Freshwater Ecology, Vol. 2, No. 3, p 225-237, December, 1983. 2 Fig. 46, Ref.

Descriptors: *Zooplankton, *Ponds, *Seasonal variations, Mountains, Population dynamics, Dissolved solids, Alkalinity, Conductivity, Limnology.

A permanent point at 3100 meters elevation was studied for an entire year to monitor zooplankton populations as they changed seasonally and associate those changes with biotic and abiotic factors. Conductivity, alkalinity, and dissolved solids were low during the summer but increased dramatically in the winter due to freezing out. Chlorophyll measurements indicated that phytoplankton reached its population maximum during the winter. The summer zooplankton community was dominated by the cladocerans, Holopedium gibberum and Daphnia rosea; the copepod, Diaptomus leptopus; the rotifers, Keratella cochlearis, Conochilus unicornis, and Polyarthra dolichoptera; and Chaoborus larvae. D. rosea disappeared from the plankton in August, possibly due to a combination of predation and competition. All limnetic Crustacea disappeared during ice cover, leaving rotifers as the most successful winter plankters. The posterior spine of K. cochlearis was long in the summer, and short or absent in the winter. This seasonal change in morphology may be a means of reducing mortality due to predation. (Baker-IVI)

BENTHIC MACROINVERTEBRATES OF SELECTED HABITATS OF THE LOWER MISSISSIPPI RIVER,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.
D. C. Beckett, C. R. Bingham, and L. G. Sanders.
Journal of Freshwater Ecology, Vol. 2, No. 3, p 247-261, December, 1983. 3 Fig, 3 Tab, 32 Ref.

Descriptors: *Macroinvertebrates, *Mississippi River, *Invertebrates, Benthic environment, Flow, Flow characteristics, Water currents, Velocity, Substrate.

The distribution of benthic macroinvertebrates was studied in four aquatic habitat types in the lower Mississippi River: dike fields, a natural bank, a secondary channel, and an abandoned channel over a high flow, two moderate, and two low flow periods. Only minor changes in composition over the various flow regimes were displayed by the biotas present in the natural bank, the secondary channel, and the abandoned channel. The natural bank was consistently dominated by the burrowing mayflies Tortopus incertus and Pentagenia vittigera and hydropsychid caddisflies; the consistently most common taxa in the secondary channel were the sand-dwelling chironomids Robackia claviger and Chernovskiia orbicus; phantom midges, tubificid oligochaetes, and fingernail clams were always the most abundant macroinvertebrates in the abandoned channel. The dike fields, however, showed large changes in biotic composition over the different flow regimes. These compositional changes correlated with changes in river stage and resultant alterations in current and substrate. The distribution of macroinvertebrates in the lower Mississippi River appears to be a function of the physical characteristics of the system, notably current velocity and substrate composition. MEASURED AND PREDICTED FLUXES OF BIOGENIC SILICA IN LAKE MICHIGAN,
Michigan Univ., Ann Arbor. Great Lakes Research Div.
C. L. Schelske, B. J. Eadie, and G. L. Krausse.
Limnology and Oceanography, Vol. 29, No. 1, p 99-110, January, 1984. 4 Fig, 3 Tab, 31 Ref. EPA grants R-806294 and R-804503.

Descriptors: *Lakes, *Silica, *Lake Michigan, Great Lakes, Seasonal variations, Sediments, Chemical analysis, Diatoms, Biogenic silica.

Because of excess phosphorus inputs, epilimnetic diatom production in Lake Michigan is limited by available supplies of silica during summer stratification. Biogenic silica fluxes obtained from sediment trap collections in the offshore waters of Lake Michigan were compared with fluxes predicted from the silica disappearance model. Measured and predicted fluxes were in good agreement for offshore stations, but at stations closer to shore measured fluxes were 2-3 times greater than predicted fluxes. Little of the diatom production was dissolved in the water column as demonstrated by sediment trap and water chemistry data. Greater than predicted fluxes must occur therefore at nearshore locations and these were attributed to new silica supplied from upwellings, tributary inputs, and recycling and resuspension in nearshore sediments. The good agreement between measured and predicted fluxes in offshore waters shows that biogenic silica fluxes may be used to determine the collecting efficiency of sediment traps. (Baker-IVI)

PREDICTION OF INTERNAL PHOSPHORUS LOAD IN LAKES WITH ANOXIC HYPOLIMNIA,
McGill Univ., Montreal (Quebec). Dept. of Biology.
G. K. Nurnberg.
Limnology and Oceanograpy, Vol. 29, No. 1, p 111-124, January, 1984. 4 Fig, 7 Tab, 61 Ref.

Descriptors: *Model studies, *Lakes, *Phosphorus load, *Hypolimnion, *Anoxic conditions, Nutrients, Eutrophication, Prediction, Phosphorus retention.

Two models are given to predict internal phosphorus load in lakes with anoxic hypolimnia. The first predicts internal load as the difference between the observed phosphorus retention in anoxic lakes and that predicted by a formula that adequately describes phosphorus retention in anoxic lakes. The second model predicts internal load as the product of an average rate of phosphorus release from anoxic sediments, the surface area of the anoxic sediment, and the period of anoxia. Predictions of the first model compare favorably with 17 observed values of internal load. These models suggest that mean phosphorus concentration in anoxic lakes can be predicted in two ways. One can use whole-lake phosphorus budget models which implicitly incorporate internal phosphorus load, because they include a measurement of phosphorus retention. Alternatively, a term to account for the internal load can be added to current models based on external load and predicted retention. (Baker-IVI)

ORIGIN OF A METALIMNETIC CHRYSOPHYTE PEAK,
Scarborough Coll., Westhill (Ontario).
F. R. Pick, C. Nalewajko, and D. R. S. Lean.
Limnology and Oceanography, Vol. 29, No. 1, p 125-134, January, 1984. 5 Fig, 1 Tab, 34 Ref.

Descriptors: *Lakes, *Chrysophyta, *Chlorophyll, *Jacks Lake, *Ontario, Algal growth, Eutrophication, Metalimnion, Chrysosphaerella, Excystment.

A metalimnetic chlorophyll peak in Jacks Lake, Ontario, was due mainly to a colonial chrysophyte, Chrysosphaerella longispina. The peak did not result from an in situ growth, nor a passive and progressive accumulation of epilimnetic cells. Rather, a sudden bloom of the algae occurred in the epilimnion at the end of June, due to excystment. This bloom then descended rapidly and after no more than 4 days, it was concentrated in a narrow band below the thermocline. No net increase was observed in chlorophyll a or cell biomass with time once the population was established in this region. No dividing cells were observed. After about 2 weeks the chlorophyll a concentration at the peak started to decline and the peak disappeared by the end of August. The measurement of chlorophyll a greatly exaggerated the importance of metalimnetic peaks. (Baker-IVI)

EFFECT OF THE ASIATIC CLAM, CORBICULA FLUMINEA, ON PHYTOPLANKTON OF THE POTOMAC RIVER, MARYLAND,
Geological Survey, Reston, VA.
R. R. H. Cohen, P. V. Dresler, E. J. P. Phillips, and R. L. Cory.
Limnology and Oceanograpy, Vol. 29, No. 1, p 170-180, January, 1984. 9 Fig, 4 Tab, 33 Ref.

Descriptors: *Rivers, *Phytoplankton, Population dynamics, Potomac River, Clams, Tidal rivers.

The freshwater, tidal Potomac River has produced high concentrations of phytoplankton during every July-September low flow period of the 1960's and 1970's, but in the summers of 1980 and 1981 phytoplankton abundance between Rosier Bluff and Hatton Point was 40-60% lower than that upstream and downstream. In 1980 and 1981 the highest biomass of the Asiatic clam, Corbicula fluminea, was in the same reach as the phytoplankton abundance 'sag.' The volume of the sag reach could be pumped through the Corbicula population in 3-4 days as indicated by filtration rates. Corbicula removed 30% of the phytoplankton chlorophyll a from a river water sample in 2 hr. Pheophytin a in surficial sediments correlated well with clam biomass as a consequence of phytoplankton excreted in pseudofeces. The theories that peak discharge, zooplankton, toxic substances, and nutrient limitation induced the sag were not supported. (Baker-IVI)

FULL DIURNAL OBSERVATIONS ON CHANGES IN APHANIZOMENON FLOS-AQUAE (L.) RALFS ON THE BACKGROUND OF PHYSICO-CHEMICAL CONDITIONS IN LAKE SWIETOKRZYSKIE DURING THE 1980 SUMMER PERIOD,
Adam Mickiewicz Univ., Poznan (Poland). Dept. of Hydrology.
L. Burchardt, and J. Panczakowa.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 3, p 229-246, 1983. 11 Fig, Tab, 28 Ref.

Descriptors: *Lakes, *Algae, *Chlorophyll, *Aphanizomenon, *Lake Swietokrzyskie, *Poland, *Diurnal variation, Seasonal variations, Nitrogen, Phosphorus, Nutrients, Eutrophication, Acidity, Dissolved oxygen, Biochemical oxygen demand.

Full diurnal algaelogic and physicochemical investigations carried out in July and August 1980 at various stages of Aphanizomenon flos-aquae blooming showed maximum numbers of Aphanizomenon flos-aquae individuals occurred in July at 21 hours and in September at 18 hours. Maximal chlorophyll c content, pH, dissolved oxygen, BOD5, and oxygen consumption occurred at the same hours. Wind direction and its force were the factors deciding the density of Aphanizomenon flos-aquae individuals in the surface water layer of Lake Swietokrzyskie (Poland). The high level of biogens in the water body resulted from the fact that no distinct differences in the value of these compounds was observed over a 124 hr period notwithstanding considerable fluctuations in the numbers of Aphanizomenon flos-aquae trichomes. Larger amounts of chlorophyll a were noted during the afternoon hours in the cells of Aphanizomenon flos-aquae from samples taken at a depth of 5.0 to 5.5 m than from the surface. It appears that for proper distinction of the processes taking place between microorganisms and the water environment full diurnal investigations will be needed at periods most critical to the water body. Maximal values for numbers of algae individuals, dissolved oxygen, BOD5, oxygen consumption and pH occurring in July and August at 21.00 and 18.00 hours indicate that these hours are the most suitable for studies aimed at evaluating the intensiveness of changes taking place in a water body during a day. SOURCES AND MOLECULAR WEIGHT OF 'DISSOLVED' ORGANIC CARBON IN AN OLIGOTROPHIC LAKE,
Marine Biological Lab., Woods Hole, MA. Ecosystems Center.
J. J. Cole, W. H. McDowell, and G. E. Likens.
OIKOS, Vol. 42, No. 1, p 1-9, January, 1984. 4 Fig, 3 Tab, 42 Ref.

Descriptors: *Dissolved solids, *Organic carbon, *Oligotrophic lakes, *Mirror Lake, *New Hampshire, Molecular weight, Water pollution sources, Ultrafiltration, Precipitation, Soil solution, Algal growth, Decomposition, Residence time.

Ultrafiltration was used to try to determine the origin of dissolved organic carbon (DOC) in Mirror Lake, New Hampshire. The distribution of molecular weights of DOC was relatively constant with depth and season, with a predominance of high-molecular weight (>100,000 daltons; 31%) and moderate-molecular weight compounds (1,000 to 10,000 daltons; 36%). The distribution of molecular weights of DOC in the lake was distinctly different from that of the DOC which entered the lake in stream water, soil solution, or precipitation. Lake water is relatively enriched in DOC above 100,000 daltons; this high-molecular weight DOC is apparently produced within the lake. One autochthonous source of DOC above 100,000 daltons is that produced during algal growth and decomposition. An input/output budget of the DOC for each molecular weight class suggested that most of the DOC in the lake resides in the lake for several years. (Author's abstract)

RIVER EPILITHON: TOWARD A STRUCTURAL-FUNCTIONAL MODEL,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
M. A. Lock, R. R. Wallace, J. W. Costerton, R. M. Ventullo, and S. E. Charlton.
OIKOS, Vol. 42, No. 1, p 10-22, January, 1984. 5 Fig, 3 Tab, 68 Ref.

Descriptors: *Rivers, *Epilithon, *Microorganisms, Diatoms, Blue-green algae, Invertebrates, Algae, Bacteria, Glycocalyx, Photosynthesis, Running waters.

Granite and epoxy resin substrates anchored in the Muskeg and Steepbank rivers (Alberta) were used to sample the epilithon. A vigorous epilithon develops both on the upper and lower surfaces of the rock and plastic substrates in these boreal rivers. The epilithic community is usually much more extensive on the upper surface; however, the epilithon on the lower surface is sometimes equally well developed and often contains large numbers of chlorophyll-containing microorganisms (both blue-green algae and diatoms). Morphological evidence suggests grazing of the epilithon by invertebrates, and clearly shows that the cellular components of this sessile community grow in distinct microcolonies within a continuous fibrous anionic matrix composed of bacterial and algal glycocalyces. The theoretical ramifications of this demonstration of a complex epilithon, in the context of bacterial digestive processes, nitrogen cycling, metal sorption, and the flux of organic matter in the stream ecosystem analyzed in terms of a structural-functional hypothetical model of the epilithon. Although algae and their associated photosynthetic capacity may at times apparently dominate the epilithon, there may be equally inportant system roles associated with the substantial heterotrophic community. Also the epilithon is a major element in running water light and organic energy transactions because of its optimum position for photosynthetic processes in many rivers and its optimum position for capturing organic energy from the overlying water. LEAF PROCESSING CAPABILITIES OF AQUATIC HYPHOMYCETES: INTERSPECIFIC DIFFERENCES AND INFLUENCE ON SHREDDER FEEDING PREFERENCES,
New Mexico State Univ., Las Cruces. Dept. of Biology.
T. L. Arsuffi, and K. Suberkropp.
OIKOS, Vol. 42, No. 2, p 144-154, January, 1984. 7 Fig, 5 Tab, 27 Ref. NSF grant DEB 7922997.

Descriptors: *Detritus, *Hyphomycetes, *Leaves, *Feeding, *Caddisflies, Decomposition, Streams, Aquatic life.

Litter inputs from the surrounding terrestrial vegetation comprise a potentially important nutrient and energy base in streams. Macroinvertebrate detritivores rely on this material as an important component of their diets, but in its original form, leaf detritus is an unsuitable food source. Leaf litter is converted by microbial activity into a more palatable and nutritional food source. Degradative abilities of aquatic hyphomycetes and the relationship between fungal-mediated conditioning of aspen leaves and feeding responses of caddisfly (Trichoptera) detritivores were examined. Interactive effects of conditioning time and fungal species were determined by conducting preference experiments in separate enclosures with all treatments (conditioning times and fungal species) or each conditioning time with all fungi. Preferences were established by comparison of leaf consumption among various treatments. Interspecific differencs among fungi in their physical-chemical modifica-

tion of aspen leaves were primarily rate-related. For three fungi, preferences exhibited by larvae were not accounted for by either the fungal species or conditioning time alone, but rather, their interaction. The most palatable leaves were those colonized with these fungi at times subsequent to the appearance of detectable pectin lyase activity. At these times, leaves were initially softened, exhibited substantial weight loss and almost doubled their nitrogen content in comparison to uninoculated leaves. Leaves colonized by one fungal species were unpalatable regardless of the degree of conditioning. (Moore-IVI)

GROWTH LIMITING FACTORS FOR OSCILLATORIA AGARDHII AND DIATOMS IN EUTROPHIC LAKES,
Oslo Univ. (Norway). Dept. of Limnology.
O. Lovstad.
OIKOS, Vol. 42, No. 1, p 185-192, January, 1984. 6 Fig, 1 Tab, 38 Ref.

Descriptors: *Oscillatoria, *Diatoms, *Eutrophic lakes, *Growth, Phosphorus, Silica, Limiting nutrients, Trace metals, Chelators.

Laboratory batch experiments were carried out to determine growth limiting nutrients and the degree of growth limitation for some diatoms and red and green forms of Oscillatoria agardhii Gom. Water samples from three lakes with average limnetic total phosphorus concentrations from 15 to 200 microg P/l were analysed. With the exception of Stephanodiscus hantzschii Grun all the diatoms investigated became growth limited at very low SRP or phosphate concentrations. Asterionella formosa Hass, probably grows more efficiently at low concentrations of phosphate than Synedra cf. acus Kutz. and Fragilaria crotonensis Kitt., but was competitively displaced at high pH levels (> 9). Stephanodiscus competitively displaced the other diatoms at low molar Si:P ratios, i.e. less than 10. Oscillatoria grew better at very high pH levels (> 10) than the diatoms. Addition of phosphate and chelated iron (FeEDTA) singly or in combination was, however, often necessary to increase the growth rate of Oscillatoria under nutrient limiting conditions. This indicates that both external concentrations of phosphate or some trace metals or chelators have to increase to above some threshold level at least during parts of the year, if Oscillatoria shall become dominant. Results of the experiment indicate that SRP and SRSi concentrations measured chemically may be similar to the available concentrations of phosphate and silicate respectively. (Author's abstract)

DECOMPOSITION OF PLANKTONIC ALGAE IN AN OLIGOTROPHIC LAKE,
02750e Biological Lab., Woods Hole, MA.
J. J. Cole, G. E. Likens, and J. E. Hobbie.
OIKOS, Vol. 42, No. 3, p 257-266, March, 1984. 7 Fig, 1 Tab, 36 Ref.

Descriptors: *Oligotrophic lakes, *Decomposition, *Algae, *Plankton, *Mirror Lake, *New Hampshire, Incubation, Particulates, Carbon dioxide, Metabolism, Bacteria.

A new procedure (dip incubation) was used to measure both the dissolution and mineralization (to CO2) of killed C-14 labelled phytoplankton in an oligotrophic lake. This procedure, based on a series of 24-h incubations in bottles, avoids the problem of extremely long incubations and can be used to measure, independently, the dissolution and mineralization rates of algal detritus of any recent age. In Mirror Lake, New Hampshire, the conversion of particulate carbon to CO2 occurred only in the presence of living microorganisms and was strongly influenced by the age of the algal detritus and the water temperature. There was a pronounced annual cycle of the conversion of particulates to CO2 with highest rates (average rate for 6 d of 6%/d) during summer and lowest rates (average rate for 6 d of 0.5%/d) in winter. In comparison to these average rates, the initial rates of both dissolution and mineralization were higher and much less dependent upon temperature. These initial rates, taken alone, would give an erroneously high estimate of the rate of decomposition and underestimate the importance of temperature as a factor controlling decomposition. We used an annual cycle of these measurements in conjunction with models of the age structure of particulate detritus to estimate the metabolism of algal C by planktonic microbes. Our estimate (3.6 to 4.3 micro g C/l/d) is comparable to previous measurements of total microbial respiration (of all C-sources) in both amount (3.1 micro g C/l/d) and annual pattern. This comparison suggests that algal carbon is a major C-source for planktonic bacteria in the epilimnion of Mirror Lake. (Author's abstract)

VARIATIONS IN THE LEVEL OF LAKE MALAWI,
University Coll., Cardiff (Wales). Dept. of Civil and Structural Engineering.
R. S. Drayton.
Hydrological Sciences Journal, Vol. 29, No. 1, p 1-12, 1984. 5 Fig, 3 Tab, 8 Ref.

Descriptors: *Water level, *Lake Malawi, Africa, Precipitation, Rainfall, Runoff, Outflow, Water balance.

Lake Malawi is the third largest lake in Africa, with an area of 28,750 sq km. Throughout this century, the water level of Lake Malawi has varied widely. During the period 1976-1980, this level rose dramatically. The causes of these changes were investigated using Monte Carlo techniques and equations based on the water balance of the lake. The model study showed that as increase in average rainfall equal to that recorded between 1915 and 1937, and between 1940 and 1979, is sufficient to have caused to recorded rise in average lake level over those periods. Changing the runoff rates in the model showed that small increases in the rate of runoff would make a significant contribution to rising lake levels. The exceptional rises of level in recent years can be attributed to the very much increased amount of freewater available to the system. This excess of freewater resulted from the very high rainfall over the lake itself, and to a lesser degree from high inflow. The high inflow resulted from above-average rainfall over the land. Man-made changes in runoff and outflow have been relatively unimportant. (Baker-IVI)

TECHNIQUES FOR DETECTING TRENDS IN LAKE WATER QUALITY,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
R. H. Montgomery, and K. H. Reckhow.
Water Resources Bulletin, Vol. 20, No. 1, p 43-52, February, 1984. 1 Fig, 3 Tab, 49 Ref. NOAA grant 03-78-B01-109.

Descriptors: *Lakes, *Water quality, *Trends, Statistical methods, Autocorrelation, Data analysis.

Information on changes in water quality over time is important for water quality management. The use of statistical techniques to detect trends in water quality parameters has the potential to provide the quantitative information needed for water resources management and planning decisions. A trend detection method is presented that provides: hypothesis formulation, the statement of the problem to be tested; data preparation, the selection of water quality variable and data; data analysis, the exploratory data analysis techniques; and statistical test, the tests for detecting trends. The starting point for the use of trend detection techniques is the determination of water quality characteristics upon which proper management and planning decisons are to be based. These characteristics determine the variables and data chosen, and the formulation of the null and alternative hypotheses. The frequent presence of autocorrelation in lake data prohibits straightforward use of most statistical techniques, including regression, based on the violation of the independence assumption. The statistical tests for dependent data are suggested for use, almost exclusively, when dealing with lake systems. The method is utilized in a stepwise fashion and is presented in a nonstatistical manner to allow use by those not well versed in statistical theory. (Moore-IVI)

CHEMICAL COMPOSITION OF SOFTWATER FLORIDA LAKES AND THEIR SENSITIVITY TO ACID PRECIPITATION,
Environmental Science and Engineering, Inc., Gainesville, FL.
C. D. Hendry, and P. L. Brezonik.
Water Resources Bulletin, Vol. 20, No. 1, p 75-86, February, 1984. 8 Fig, 5 Tab, 48 Ref. EPA grant 805560.

Descriptors: *Florida, *Softwater lakes, *Acid rain, Aluminum, Nutrients, Chlorophyll a, Hydrogen ion concentration, Alkalinity, Sulfates, Acidification, Lakes.

Based on alkalinity data for 596 lakes, 31% of Florida's 7300 lakes have < 100 micro eq/L alkalinity and are sensitive to acid deposition. More than two-thirds of the lakes in 12 northern Florida counties fit this criterion. Increasing aluminum and decreasing nutrient and chlorophyll a concentrations were observed with decreasing pH in a survey of 20 softwater lakes. Maximum measured aluminum values (100-500 micro g/L) are below levels associated with fish toxicity. Factor analysis showed that lake chemistry was related to three principal factors, representing three major processes: watershed weathering, acidification, and nutrient inputs. An acidification index defined as the difference between excess SO4(2-) and excess (Ca(2+) + Mg(2+)) accounted for 74% of the variance in lake pH. Comparison of historical (late 1950s) and present data for pH, alkalinity, and excess SO4(2-) indicated loss of alkalinity (> 25 micro eq/L) and increases in excess SO4(2-) (16-34 micro eq/L) in several softwater lakes. (Author's abstract)

DYNAMICS OF ADDED NITRATE AND PHOSPHATE COMPARED IN A NORTHERN CALIFORNIA WOODLAND STREAM,
William Paterson Coll. of New Jersey, Wayne. Dept. of Biology.
M. J. Sebetich, V. C. Kennedy, S. M. Zand, R. J. Avanzino, and G. W. Zellweger.
Water Resources Bulletin, Vol. 20, No. 1, p 93-101, February, 1984. 5 Fig, 1 Tab, 44 Ref.

Descriptors: *Nitrates, *Phosphates, *Little Lost Man Creek, *California, Cycling nutrients, Dispersion, Streams, Biota, Sediments.

Injections of NO3 and PO4 were made during September 1975 into Little Lost Man Creek, a small pristine stream in Redwood National Park, California. Chloride, a conservative constituent, was added in a known ratio to the nutrients. Nutrient loss at a downstream point was calculated using concentration of added Cl as a reference. Nitrate nitrogen (NO3-N), added for 4 h, reached 920 micro g/l (above 5 micro g/l background) just below the injection point, but increased only to 405 micro g/l at 310 m downstream. The concentration decrease was attributed to dispersion and to uptake by stream biota. Percent of NO3-N lost decreased with increasing concentration of NO3-N. Phosphate phosphorus (PO4-P) was added a week after the NO3-N for 3 h, causing a concentration increase of 296 micro g/l (above 13 micro g/l background) just below the injection point, of 161 micro g/l at 90 m downstream, and of 98 micro g/l at 310 m. Percent loss of PO4-P at downstream sites increased with increasing PO4-P concentration and also for a short period after peak concentration occurred, but then decreased as PO4-P concentration continued decreasing. Differences in stream response to added NO3-N and PO4-P are attributed to differing rates of reaction with biota and differing degrees of interaction with abiotic stream solids. (Author's abstract)

WATERBORNE NUTRIENT BUDGETS FOR THE RIPARIAN ZONE OF AN AGRICULTURAL WATERSHED,
Georgia Univ., Athens. Inst. of Ecology.
R. R. Lowrance, R. L. Todd, and L. E. Asmussen.
Agriculture, Ecosystems and Environment, Vol. 10, No. 4, p 371-384, December, 1983. 4 Fig, 4 Tab, 26 Ref. NSF grants DEB 78-10841 and DEB 82-07210.

Descriptors: *Forests, *Agricultural watersheds, *Nutrients, *Riparian vegetation, Nitrogen, Phosphorus, Calcium, Magnesium, Land management, Groundwater, Precipitation, Land use, Cropland.

Agroecosystems in the southeastern United States Coastal Plain typically have uplands in agriculture with mixed hardwood forests along the stream channels. This study determined the inputs and outputs of waterborne nutrients for the riparian forest ecosystem of an agricultural watershed. Quantities of phreatic groundwater and precipitation nutrient inputs and phreatic and surface nutrient outputs were determined during 1979. Based on input/output budgets, these streamside forests were shown to be effective in retaining N, P, Ca, and Mg. Partial conversion of the riparian forest to cropland was projected to increase NO3-N and NH4-N loads by up to 800%. Total replacement of riparian forest with crops would increase loads of all nutrients studied except organic N, DMRP, and total P. Land managers can maintain the nutrient filtering capacity of the streamside forest by selective harvesting of hardwoods and by maintaining the present hydrologic regime. (Author's abstract)

STRUCTURE AND ANNUAL BIOMASS PRODUCTION OF NYMPHOIDES PELTATA (GMEL.) O. KUNTZE (MENYANTHACEAE),
Katholieke Univ., Nijmegen (Netherlands). Lab. of Aquatic Ecology.
Th. C. M. Brock, G. H. P. Arts, I. L. M. Goossen, and A. H. M. Rutenfrans.
Aquatic Botany, Vol. 17, No. 3/4, p 167-188, December, 1983. 4 Fig, 6 Tab, 39 Ref.

Descriptors: *Nymphoides, *Biomass, *Aquatic plants, *Bemmelse Strang, *Netherlands, Cycling nutrients, Oxbow lakes, Seasonal variation, Submerged plants.

In shallow backwater of the river Waal (Netherlands), the floating leaved macrophyte Nymphoides peltata is common and often represents the dominant vegetation. In 1980 and 1981, the structure and aspects of production, consumption, decomposition, and nutrient cycling of N. peltata were studied quantitatively the the Bemmelse Strang, an oxbow lake of the river Waal. The seasonal changes in the vertical stratification of the biomass were studied in concrete tanks. These seasonal changes were studied with the harvest method, while the estimation of the net primary production was based upon biomass data and turnover rates of various plant parts. The morphological differentiation of N. peltata into roots, short shoots, long shoots, petioles, leaf blades and flowering structures offers a variety of habitats for the accompanying organisms. An important function of N. peltata is the supply of substrates for periphytic organisms. The data are compared with those of other water plants, especially other floating-leaved macrophytes. The maximum submerged surface area supplied by N. peltata in the Bemmelse Strang is intermediate between those reported for emergent and submerged macrophytes. In 1980, N. peltata reached its peak biomass in August being 372 g AFDW/sq m (ash-free dry weight). The annual net productivity of Nymphoides was estimated to be 1036 g AFDW/sq m. The leaf blades and their petioles contributed most to the production. (Moore-IVI)

FACTORS AFFECTING NITROGENASE ACTIVITY ASSOCIATED WITH MARSH GRASSES AND THEIR SOILS FROM EUTROPHIC LAKES,
Dundee Univ. (Scotland). Dept. of Biological Sciences.
M. T. Ogan.
Aquatic Botany, Vol. 17, No. 3/4, p 215-230, December, 1983. 6 Fig, 3 Tab, 28 Ref.

Descriptors: *Grasses, *Nitrogenase, *Soil water, *Eutrophic lakes, Nitrogen, Phosphorus, Phalaris, Phragmites, Temperature, Sunlight, Marshes, Diurnal variation.

The acetylene reduction activity (ARA) of soil-plant cores and intact, soil-free plant-root systems was used to study the influence of soil moisture content, diurnal cycles of temperature and light, and inorganic N and P on the nitrogenase activity (AR) associated with Phalaris arundinacea L. and Phragmites australis (Cav.) Trin. from two eutrophic lakes (lochs), Balgavies and Forfar. A positive correlation ($r = 0.81$, $n = 26$) was established between AR and soil moisture content in individual soil-plant cores of Phalaris from Forfar Loch. Nitrogenase activity, soil moisture and NO2(-)-N increased with decreasing distance from lake water in Balgavies Loch. Diurnal fluctuations in AR, probably attributable to a combined effect of soil temperature and illumination changes, were observed under field conditions for Phalaris and Phragmites. Under laboratory conditions, the shading and cutting of Phalaris shoots did not inhibit ARA, which suggested that new photosynthates did not necessarily supply substrate for activity in the short term. Partial and temporary inhibition of ARA was obtained in dissected soil-plant cores after a single application of NH4(+)-N and NO3(-)-N (350 micro g N/g fresh weight). At concentrations equivalent to 300 micro g P/g fresh weight of Phalaris cores, PO4(3-)-P also caused partial and temporary inhibition of ARA of soil-free plant-root systems, but stimulated activity in intact simulated in situ systems. PHYTOSOCIOLOGICAL STUDY OF THE MACROPHYTIC VEGETATION OF RUNNING WATERS IN WESTERN LOWER SAXONY (FEDERAL REPUBLIC OF GERMANY),
Oldenburg Univ. (Germany, F.R.). Dept. of Biology.
G. Wiegleb.
Aquatic Botany, Vol. 17, No. 3/4, p 251-274, December, 1983. 2 Fig, 3 Tab, 77 Ref.

Descriptors: *Macrophytes, *Rivers, *Western Lower Saxony, *West Germany, Vegetation, Aquatic plants, Plant communities.

A survey was carried out of the macrophytic vegetation in running waters of Western Lower Saxony. Three hundred and eighty-two phytosociological relevees were classified by common table work to 30 vegetation types of different phytosociological validity. The vegetation types are described and floristically characterized. Most of them belong to the complex Sparganium emersum community, which is characterized by the dominant occurrence of the nymphaeid species Sparganium emersum Rehm., Nuphar lutea (L.) Sm., Sagittaria sagittifolia L. and Potamogeton natans L., but magnopotamid-, parvo-potamid-, batrachiid- and pleustophyte-dominated communities also occur. Similarity between the different vegetation types was checked by multivariate techniques, one classification technique (minimum variance clustering) and one ordination techniques (principal components analysis). Additionally, syndynamical relations between the types were studied by observing the vegetation changes of 46 sample points within 2 years. The relations between different vegetation types are shown by combination of the different approaches. Finally, some more general statements are made regarding the handling of such data sets, as well as the consequences of the results for the classification of macrophytic vegetation in Central European rivers. TESTS FOR EVALUATING THE STATUS OF ECOSYSTEMS OF FRESH WATER LAKES WITH MULTIPLE USE,
Moscow State Univ. (USSR).
A. S. Konstantinov.
Hydrobiological Journal, Vol. 19, No. 1, p 1-10, 1983. 2 Fig, 31 Ref.

Descriptors: *Ecosystems, *Lakes, Energy, Reviews, Aquatic life, Hydrobiology.

Tests for evaluating aquatic ecosystems as elements of the biosphere are discussed. The tests are based on the concept of evolution of the biosphere as a system subordinated to the cosmos. The ecosystem energy characteristics, which are of great criterial significance, presently are extremely unsatisfactorily determined due to procedural errors in the hydrobiological determination of production and decomposition. The view of the biosphere as a subsystem of the cosmos allows forecasting the possible consequences of changes in water ecosystems to be made more accurately and supports human efforts to protect the environment. PHYTOPLANKTON OF THE KURTLINSKOYE RESERVOIR,
Akademiya Nauk Turkmenskoi SSR, Ashkhabad. Inst. Botaniki.
Sh. I. Kogan, and Yu. Ue. Lyubeznov.
Hydrobiological Journal, Vol. 19, No. 1, p 11-17, 1983. 2 Fig, 5 Tab, 22 Ref.

Descriptors: *Phytoplankton, *Reservoirs, Kurtlinskoye Reservoir, Eutrophication, Nutrients, Runoff, Agricultural runoff, Water quality.

Long-term studies in the Kurtlinskoye (Turkmenia) reservoir showed that the structure and quantitative development of the phytoplankton there underwent significant changes due to extermination of vascular aquatic plants by the grass carp, and increased pollution. A sharp increase in phytoplankton biomass, oxygen deficit, content of nutrients, oxidizability, and biological oxygen demand suggests that the reservoir is becoming eutrophic. The major cause of pollution in this region is due to increased nutrients entering the water as a result of agricultural runoff. In recent years the fraction of beta-mesosaprobes has increased and that of the oligosaprobes has decreased somewhat. Three periods of development have been isolated from intensive study concerning the phytoplankton in the reservoir. The first period (1966-1970) involved weak quantitative development of the phytoplankton, with maximum taxonomic diversity. The second period (1970-1975) involved a major restructuring of the biocoenosis as a result of the destruction of the vascular plants, and development of the phytoplankton to initial bloom stage. The dominant complex was unstable, and the saprobicity increased. The third period (1975-1978) involved a further increase in the plankton biomass. The plankton community showed only slight yearly changes in composition and productivity. Proper management of the Kurtlinskoye Reservoir is needed if further deterioration of water quality is to be avoided. (Baker-IVI)

MACROBENTHOS COMMUNITIES OF THE NORTH CRIMEAN CANAL,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
T. A. Kharchenko.
Hydrobiological Journal, Vol. 19, No. 1, p 37-44, 1983. 7 Fig, 1 Tab, 15 Ref.

Descriptors: *Canals, *Macrobenthos, Macrozoobenthos, North Crimean Canal, Invertebrates, Decomposition, Organic matter.

The main coenoses of macrozoobenthos in the North-Crimean Canal (NCC) were identified. The energy flow through these coenoses was calculated. A more productive coenosis exists in the end zone of the canal. Two macrobenthos invertebrate communities were identified in the NCC. Based on an analysis of the species makeup, numbers, biomass, species frequency and metabolic processes of the individual groups of hydrobionts, with allowance for environmental factors, the first bottom coenosis identified in the canal has been named L. hoffmeisteri + P. breviantennatum community of sand clay bottom soils, and the second has been named the Dreissena + p. ferrugineus + D. hae-

mobaphes community of silted clay bottom soils. Decomposition of organic matter is proceeding actively in the canal, prompted to a certain extent by the functioning of the Dreissena consortium. Discovering the mechanism of this effect is a task for future study. (Baker-IVI)

ECOLOGIC PHYSIOLOGY AND BIOCHEMISTRY OF AQUATIC PLANTS AND MICROORGANISMS: CONTRIBUTION TO THE BIOLOGY AND COENOLOGY OF POTAMOGETON PERFOLIATUS L.,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
Sh. Gusak, A. I. Merezhko, and V.P. Gorbik.
Hydrobiological Journal, Vol. 19, No. 1, p 54-58, 1983. 5 Fig, 3 Tab, 8 Ref.

Descriptors: *Reservoirs, *Aquatic plants, Microorganisms, Kiev Reserovir, Plant growth, Seasonal variation, Distribution.

The structure and biomass of Potamogeton perfoliatus thickets, as well as biometric data on this species were considered in the Strakholesiye shallows of the Kiev Reservoir. Plant biomass was sampled over an area of 100 sq m at a depth of 1.6 m. The Howard-Williams and Longman sampler made it possible to collect samples of plants not only from the surface, but also from the depths. Lateral distribution in the thickets is heterogeneous both in the number of sprouts and biomass. Average biomass was 258 g of bone dry matter, per sq m, most of it concentrated below the first 1.8 m of the plant height. Mean leaf area per sq m of the thickets was 1.72 sq m. In studying the structure of beds of P. perfoliatus, account must be taken not only of the size of the patches, but also of the distribution (density) of plants in them, bearing in mind the nature of the biotope. (Baker-IVI)

ECOLOGICAL CHARACTERISTICS OF PHOTOSYNTHESIS OF PHYTOPLANKTON AND ITS ROLE IN THE ECOSYSTEM OF THE DNIEPER RESERVOIRS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
A. D. Priymachenko.
Hydrobiological Journal, Vol. 19, No. 1, p 59-67, 1983. 6 Fig, 3 Tab, 10 Ref.

Descriptors: *Reservoirs, *Phytoplankton, Photosynthesis, Dnieper Reservoir, Eutrophication, Primary productivity.

The vertical distribution of the photosynthetic production and of the biomass of the phytoplankton in the Dnieper Reservoirs is expressed by curves of different kinds that do not correlate with one another. Most of the water columns of the Dnieper Reservoirs are fairly well saturated with phytoplankton. Photosynthesis occurs only in the surface layer, depending on insolation. When the density of algae is higher than 40 g/cubic m, photosynthesis rates decrease due to self-shading and reduction in the specific area per unit biomass. The role of phytoplankton in formation of organic matter, its decomposition and as a source of energy resources increases with trophicity of the water. (Baker-IVI)

WATER HUMUS IN LAKES LADOGA AND BAIKAL,
Akademiya Nauk SSSR, Borok. Inst. Biologii Vnutrennykh Vod.
B. A. Skopintsev.
Hydrobiological Journal, Vol. 19, No. 1, p 88-93, 1983. 2 Tab, 19 Ref.

Descriptors: *Plankton, *Lakes, Lake Ladoga, Lake Baikal, Oligotrophic lakes, Decomposing organic matter.

The nature of the water humus in the oligotrophic Lakes Ladoga and Baikal is considered. Allochthonous, terrigenic humus of soil and bog origin dominates in Lake Ladoga; autochthronous, planktonogenic humus in Lake Baikal. The analytical criteria were water color, rate of phytoplankton production, ratios between permanganate oxidizability and bichromate oxidizability and organic carbon. Validity of such an approach is confirmed by results of studies of different researchers on the nature of soil humus, sapropel, plankton and planktonogenic humus of waters and benthic deposits of the ocean and certain seas. Aromatic (cyclic) compounds are proved to dominate in terrigenic humus and aliphatic (acyclic) ones in the planktonogenic humus. (Baker-IVI)

WATER BALANCE OF A SMALL LAKE USING STABLE ISOTOPES AND TRITIUM,
Commonwealth Scientific and Industrial Research Organization, Glen Osmond (Australia). Div. of Soils.
J. V. Turner, G. B. Allison, and J. W. Holmes.
Journal of Hydrology, Vol. 70, No. 1-4, p 199-220, 1984. 14 Fig, 7 Tab, 21 Ref.

Descriptors: *Lakes, *Hydrologic budget, *Blue lake, *Australia, *Isotopic tracers, *Tritium, Recharge, Groundwater, Residence time, Carbon radioisotopes, Oxygen radioisotopes, Deuterium.

A small maar lake, known as the Blue Lake, set in a karstic region of southeastern Australia, provides the municipal water supply for a population of approximately 20,000. The lake has a volume of 36,000,000 cu m, of which 10-15% is pumped from it each year. The lake is recharged almost entirely from groundwater and the main objective of this study was to estimate the total groundwater inflow and outflow rates. Estimation of groundwater throughflow in a lake is different to assess using classical hydrological techniques and an alternative method involving measurement of the concentrations of the environmental isotopes H-3, O-18, H-2 and C-14 in the lake water and in the recharging groundwater was used to establish the lake-water balance. The water-balance calculations indicated a total groundwater inflow to Blue Lake of between 5,000,000 and 6,500,000 cu m/yr, corresponding to a residence time of water in the lake of approximately 6 yr. It was not possible to derive the relative proportions of inflow to the lake from the two possible source aquifers, using these isotopes, because their concentrations did not show a sufficiently large contrast to distinguish the two water sources. HOLOCENE DEPLETION AND ACTIVE RECHARGE OF THE KALAHARI GROUNDWATERS - A REVIEW AND AN INDICATIVE MODEL,
Botswana Univ., Gaborone. Dept. of Geology.
J. J. De Vries.
Journal of Hydrology, Vol. 70, No. 1-4, p 221-232, 1984. 5 Fig, 1 Tab, 18 Ref.

Descriptors: *Kalahari desert, *Groundwater recharge, *Holocene, *Groundwater depletion, Topography, Infiltration, Aquifers, Hydraulic gradient.

Groundwater has been encountered in a large number of successful drillings in the Kalahari desert in different areas and formations. Locations of wells and boreholes are unevenly distributed and mostly related to topographic sites where groundwater can be found at shallow depth. A question in the evaluation of groundwater resources in the Kalahari is whether there is any active infiltration of present-day rainfall to the deep aquifers. The present study investigates whether the regional hydraulic gradient means a modern replenishment, or whether the slope of the piezometric surface should be explained as a residual feature resulting from head decay since the last pluvial period. The hydraulic gradient is most probably of a residual nature, and the replenishment has been less than 0.5 mm/yr during at least the last 4000 yr. The present groundwater depth and hydraulic gradient can be explained as a residual head caused by groundwater depletion due to an exceedance of discharge over recharge. The present-day discharge is most probably less than 0.5 mm/yr, and is either in dynamic equilibrium with current recharge, or still exceeds recharge, so that groundwater depletion will continue. Isotope studies gave evidence of local recharge to the Kalahari beds in areas favored by a combination of concentrated surface water and high permeability, creating local aquifers. (Moore-IVI)

SEASONAL CHANGE OF CHLOROPHYLL-A WITH BACTERIOCHLOROPHYLL IN LAKE FUKAMI-IKE,
Nagoya Women's Univ. (Japan). Faculty of Home Economics.
A. Yagi, I. Shimodaira, H. Terai, and Y. Saijo.
Japanese Journal of Limnology, Vol. 44, No. 4, p 283-292, October, 1983. 9 Fig, 13 Ref.

Descriptors: *Bacteria, *Phytoplankton, *Seasonal variation, *Chlorophyll, *Lake Fukami-ike, *Japan, Chlorophyll a, Chlorophyll c, Stratification.

Lake Fukami-ike is a small lake in central Japan having a maximum depth of 8.5 m, and is well protected from the wind. The lake has no inflowing streams, but it receives the runoff water from paddy fields, orchards and a certain amount of domestic sewage. The lake was stratified from March to October and circulated from November to March. Anoxic condition prevailed below 4-5 m depth from April to October. The amount of chlorophyll-a in the euphotic layer was low during the stagnation period, and high during the circulation period. Such a seasonal change in chlorophyll-a amount might be caused by: the interruption of upwards nutrient transportation form the tropholytic layer due to a distinct stagnation of water and the consumption of nutrients by photosynthetic sulfur bacteria growing near the top of anoxic layer in summer; and the sequential change of circulation and stagnation of water, producing favorable conditions for phytoplankton growth in winter. The highest values for bacteriochlorophyll c, about 140 to 120 micro g/l, were found near the top of the anoxic layer in the summer. (Moore-IVI)

DAILY OXYGEN BUDGETS IN A SUBMERGED PLANT STAND IN BROA RESERVOIR, SOUTHERN BRAZIL,
Chiba Univ. (Japan). Inst. of Marine Ecosystem.
I. Ikusima, K. Hino, and J. G. Tundisi.
Japanese Journal of Limnology, Vol. 44, No. 4, p 304-310, October, 1983. 4 Fig, 4 Tab, 10 Ref.

Descriptors: *Oxygen budget, *Aquatic plants, *Broa Reservoir, *Brazil, Standing crop, Photosynthesis, Algae, Diffusion, Respiration.

Daily oxygen budgets within a stand of submerged plants were measured in August, with the use of five cylindrical plastic tubes with different enclosure systems. The standing crop of living and dead plants at the experimental site was 47.9 and 37.5 g dry matter/sq m, respectively. Both daily total oxygen addition and that of oxygen loss in the water at the sand were estimated as 3.24 g O2/sq m/day. Daily gross productions of oxygen through photosynthesis by the submerged plants with their epiphytic algae and by epipelic algae accounted for 36% and 37% of the total oxygen addition, respectively. As much as 47% of the total loss was due to air released from water through diffusion, and 36% of that was due to total respiration. Both the daily amount of diffusion and its direction mainly depended upon the dissolved oxygen concentration at the researched water; daily amount of diffusion from water to air was estimated as 1.51 g O2/sq m/day, and the highest rate of oxygen diffusion was 0.21 g O2/sq m/hr for 12-15 hours, when the rate of net oxygen production of 0.32 g O2/sq m/hr was sustained. 2I. Water In Plants

EFFECTS OF WATER STRESS ON THE WATER RELATIONS OF PHASEOLUS VUL-

GARIS AND THE DROUGHT RESISTANT PHASEOLUS ACUTIFOLIUS,
Agricultural Research and Education Center, Lake Alfred, FL.
L. R. Parsons, and T. K. Howe.
Physiologia Plantarum, Vol. 60, No. 2, p 197-202, 1984. 4 Fig, 1 Tab, 29 Ref.

Descriptors: *Water stress, *Plant water potential, *Drought resistance, *Tepary bean, Leaves, Water potentials, Moisture deficiency.

Drought resistant plants can use sevaral mechanisms to postpone or tolerate dehydration. These include reduction of water loss by increased stomatal resistance, reduction of absorbed radiation by changes in leaf orientation, or reduction in leaf area. Mechanisms that tend to promote drought tolerance by maintaining turgor include osmotic adjustment, an increase in cell wall elasticity, or a decrease in cell size. The tepary bean (Phaseolus acutifolius Gray var. latifolius), a drought resistant species, was compared under water stress conditions with the more drought susceptible P. vulgaris L. cvs Pinto and White Half Runner (WHR). In order to better understand the basis for the superior drought resistance of tepary, this study was designed to determine the relationships among leaf water potential, osmotic potential, turgor potential, and relative water content (RWC). Plants were prestressed by withholding irrigation water. These stress pretreatments changed the relation between leaf water potential and relative water content of both species so that prestressed plants had lower water potentials than controls at the same leaf RWC. Tepary had lower water potentials at given RWC levels than Pinto or WHR; this can account for part of the superior resistance of tepary. In all genotypes, prestressed plants maintained osmotic potentials approximately 0.2 MPa lower than controls. Tepary reached osmotic potentials that were significantly lower (0.15 to 0.25 MPa) than Pinto or WHR. Both control and prestressed tepary plants had 0.05 to 0.25 MPa more turgor than Pinto or WHR at RWC values between 65 and 80%. Both prestressed and control tepary plants had greater elasticity (a lower elastic modulus) than Pinto or WHR. This greater turgor of tepary at low RWC values could be caused by several factors including greater tissue elasticity, active accumulation of solutes, or greater solute concentration. Tepary had significantly lower osmotic potentials than the P. vulgaris cultivars, but there was little difference in osmotic potential between Pinto and WHR. Knowledge of differences in osmotic and turgor potentials among and within species could be useful in breeding for drought resistance in Phaseolus. (Murphy-IVI)

GROWTH, WATER POTENTIAL AND ION ACCUMULATION IN THE INLAND HALOPHYTE ATRIPLEX TRIANGULARIS UNDER SALINE FIELD CONDITIONS,
Ohio Univ., Athens. Dept. of Botany.
T. E. Riehl, and I. A. Ungar.
Acta Oecologica-Oecologia Plantarum, Vol. 4, No. 1, p 27-39, 1983. 5 Fig, 5 Tab, 24 Ref. NSF grant DEB7927236.

Descriptors: *Plant growth, *Saline soils, *Atriplex, Water potentials, Plant water potential, Salt marshes, Sodium, Chlorides, Rittman, Ohio.

Atriplex triangularis, an annual halophyte in the family Chenopodiaceae, has a wide distribution but generally occurs in inland and coastal salt marshes. The effect of soil conditions on the growth and distribution of A. triangularis were investigated on an inland salt marsh at Rittman, Ohio. The study site consists of three zonal communities, each dominated by populations of a single species. Atriplex plants which grow adjacent to the Salicornia zone (Atriplex wet zone) are subjected to generally more saline and wetter soils than those growing nearer to Hordeum-Atriplex zone (Atriplex dry zone) or those growing with Hordeum jubatum (Hordeum-Atriplex zone). Plant dry matter production in the most highly saline habitats was less than 50% of that in the less saline sites. In the most saline environment, all plants were dead by the end of July prior to reaching the flowering stage. Increases in soil salinity were significantly correlated with increasing sodium and chloride ion content and more negative water potentials in roots and shoots of A. triangularis. High plant densities also reduced dry weight production in A. triangularis. (Baker-IVI)

EFFECTS OF WATER AND NITROGEN SUPPLY ON THE COMPETITION BETWEEN THREE PERENNIAL MEADOW GRASSES,
California Univ., Irvine. Dept. of Ecology and Evolutionary Biology.
M. R. Sharifi.
Acta Oecologica-Oecologia Plantarum, Vol. 4, No. 1, p 71-82, 1983. 4 Fig, 3 Tab, 36 Ref.

Descriptors: *Meadows, *Plant growth, *Grasses, *Nitrogen, *Water supply, Stress, Bromus, Alopecurus, Arrhenatherum, Groundwater.

The biomass production with and without competition of Alopecurus pratensis, Arrhenatherum elatius, and Bromus erectus was examined in lysimeter experiments using three different levels of nitrogen fertilization and water supply. Alopecurus was the strongest competitor under almost all conditions, while Bromus was the weakest competitor. The success of Arrhenatherum in mixed culture varied with ground water level and nitrogen fertilization. The physiological behavior of Alopercurus was similar to its ecological behavior. Arrhenatherum was forced into drier, nitrogen-poorer conditions by Alopecurus. Bromus was encroached upon by both other species under all conditions. The concept of competition and its effects on the ecological behavior of these three species is discussed. The major conclusion was that while stress tolerators such as Bromus erectus, grow in areas where there is competition, they grow much better in stress free situations. (Baker-IVI)

WATER STRESS AND TREE PHENOLOGY IN A TROPICAL DRY FOREST IN THE LOWLANDS OF COSTA RICA,
P. B. Reich, and R. Borchert.
Journal of Ecology, Vol. 72, No. 4, p 61-74, March, 1984. 3 Fig, 34 Ref.

Descriptors: *Water stress, *Trees, *Phenology, *Costa Rica, Tropical region, Seasonal variation, Plant growth, Plant water potential, Available water.

It has long been recognized that seasonal changes in the physiognomy of tropical forests are caused primarily by seasonal variation in rainfall, which in conjunction with soil moisture availability is the principal determinant of tree water status. Phenology and seasonal variations in water stress, as indicated by variations in girth, were monitored for 1 yr in numerous trees of twelve species, growing at dry and moist sites in a tropical lowland deciduous forest in Guanacaste, Costa Rica. At dry sites, trees experienced water stress and shed their leaves early in the dry season. In most species, rehydration, followed by bud break, took place only after heavy rainfalls. In some species, leaf shedding was followed by rehydration and bud break during continuing drought. During shoot extension, which rarely lasted longer than a few weeks, trees experienced water stress in spite of growing in wet soils. At wet sites, trees experienced little or no apparent water stress; they remained evergreen or rapidly exchanged leaves during the dry season. In general, the timing of leaf fall and bud break and, in many species, anthesis was determined to a large extent by changes in tree water status. These phenomena, in turn, were a function of the interaction between the water status of the environment and the structural and functional state of the tree. At times the functional state of the tree would counteract the environmental influences; trees with growing shoots experienced temporary water deficits during the wet season, and bare trees rehydrated during drought. The seasonal pattern of tree development had a high correlation with seasonal variation in tree water status, but only indirectly with environment water availability. No evidence was found for the control of tree development by seasonal variation in photoperiod or temperature. (Murphy-IVI)

WATER RELATIONS OF DACTYLIS GLOMERATA AND DICHANTHIUM ISCHAEMUM CULTIVATED UNDER TWO DIFFERENT WATER REGIMES (RELATIONS HYDRIQUES CHEZ DACTYLIS GLOMERATA ET DICHANTHIUM ISCHAEMUM CULTIVES SOUS DEUS REGIMES HYDRIQUES CONTRASTES),
Thessalonika Univ., Salonika (Greece). Lab. de Science des Paturages.
B. Noitsakis, and A. Berger.
Acta Ecologia, Vol. 5, No. 1, p 75-88, 1984. 8 Fig, 3 Tab, 33 Ref.

Descriptors: *Plants, *Water stress, *Dactylis, *Dichanthium, Stomata, Temperature effects, Hydrologic budget.

The relative occurrence of the two plant types, C3 species and C4 species, has most often been related to their different responses to temperature. Responses to water stress have recently been investigated in Dactylis glomerata (C3) and Dichanthium ischaemum (C4). Water balance by the C3 species is characterized mainly by a regulation of stomatal conductance, which shows a plastic response to water stress. The C4 species is characterized by high root and stem conductance and by a low plasticity of stomatal regulation. Hydrodynamic characteristics of the leaves are plastic in both species. The C3 species response is likely controlled more by photoperiod than by water stress while that of the C4 species is independent of photoperiod but is controlled by water stress. (Baker-IVI)

SOIL AND XYLEM WATER POTENTIAL AND SOIL WATER CONTENT IN CONTRASTING PINUS CONTORTA ECOSYSTEMS, SOUTHEASTERN WYOMING, USA,
Wyoming Univ., Laramie. Dept. of Botany.
T. J. Fahey, and D. R. Young.
Oecologia, Vol. 61, No. 3, p 346-351, March, 1984. 5 Fig, 1 Tab, 24 Ref.

Descriptors: *Soil water, *Soil water potential, *Soil-water-plant relationships, *Xylem water potential, *Pine, *Wyoming, Water stress, Rhisosphere moisture, Soil porosity, Soil structure.

The relationships between volumetric soil water content (theta), in situ soil water potential (psi soil) and predawn xylem pressure potential (psi predawn) were quantified in four contrasting lodgepole pine ecosystems in Wyoming, USA. On three of the sites, changes in psi soil correlated closely with psi predawn, but on a porous soil derived from coarse granitic parent material, psi predawn declines occurred much sooner than corresponding declines on psi soil, possibly because of local depletion of rhizosphere moisture and low molecular diffusivity of water in that soil. Extrapolation of laboratory-derived characteristic curves for soil moisture to field conditions yielded different relationships between theta and psi soil than curves derived from in situ measurements, probably because of disruption of soil structure and porosity during samples collection and handling in laboratory studies. Although a close correlation between theta and psi predawn was observed, future efforts at modelling the soil-plant-atmosphere continuum should be directed towards a more detailed understanding of the complex relationships between psi soil at varying depths and plant water stress. (Author's abstract)

WATER LOSS AND MALATE FLUCTUATIONS DURING THE DAY FOR PLANTS IN THE SOUTHERN NAMIB DESERT,
Bayreuth Univ. (Germany, F.R.).
D. J. v. Willert, E. Brinckmann, B. M. Eller, and B. Scheitler.
Oecologia, Vol. 61, No. 4, p 393-397, March, 1984. 3 Fig, 1 Tab, 15 Ref.

Descriptors: *Desert plants, *Water loss, *Transpiration, *Namib desert, Photosynthesis, Leaf conductance, Malate, Succulence.

The daily course of transpiration for 12 different plants growing in the southern Namib desert was investigated. Sclerophyllous species with C3 photosynthesis were the most effective water savers followed by succulents exhibiting CAM, while C3 pathway-succulents lose as much water as malacophyllous species. The different species showed either one or two peaked patterns of both transpiration and leaf conductance. With C3 plants the most common pattern is a single morning peak in leaf conductance followed by decreases in conductance over the remainder of the day. With CAM succulents leaf conductance is high in the morning, shows a pronounced midday depression and increases in the early afternoon when the malate pool is depleted, but malate consumption did not start earlier than 4 h after dawn. Seven of nine investigated C3 plants had rather high contents of malate, up to 180 micromol/g dry matter. In these plants the malate content increased with increasing leaf conductance and disappeared when leaf conductance declined in the evening, indicating that malate was synthesized during photosynthesis. MEASUREMENT OF BEDLOAD DISCHARGE IN NINE ILLINOIS STREAMS WITH THE HELLEY-SMITH SAMPLER,
Geological Survey, Urbana, IL. Water Resources Div.
J. B. Graf.
USGS Water-Resources Investigations Report 83-4136, 1983. 70 p, 10 Fig, 28 Tab, 11 Ref.

Descriptors: *Bedload discharge, *Sediment transport, *Fluvial sediments, Rivers, Sampling, *Helley-Smith bedload sampler, *Bedload discharge rating curves, *Illinois.

Samples collected with the Helley-Smith bedload sampler provide useful information about transport of sand-size sediment in Illinois streams. Samples provide the basis for bedload-discharge rating curves for the Rock and Kaskaskie Rivers and Henderson Creek. Comparison of measured bedload discharge with bedload discharge computed for selected flow conditions from channel characteristics allows the selection of an appropriate indirect method for determining bedload discharge for the Spoon, Kishwaukee, and Edwards Rivers. No one indirect method best represents bedload discharge in studied streams. No bedload-discharge rating curve was developed for the La Moine River, because the two measured bedload discharges are not sufficient for development of a rating curve and do not agree well with discharges computed by any of the three indirect methods. The dominant size of bedload particles in all streams sampled give results which cannot be used at this time. Collection-bag clogging may have been significant in the Green River, and large bed material gains or high flow velocities may have interfered with the operation of the sample in the Vermilion River. PRINCIPLE AND APPLICATION OF SEDIMENT EFFECTIVE POWER,
Tianjin Univ. (China). Dept. of Hydraulic Engineering.
S-Y. Wang.
Journal of Hydraulic Engineering (ASCE), Vol. 110, No. 2, p 97-107, February, 1984. 5 Fig, 4 Tab, 13 Ref. NSF grant ENG 7825054.

Descriptors: *Sediment effective power, Mathematical models, Sediment-water interfaces, Sediment transport, Open channel, Bed load, Sediment concentration, Sediment-carrying capacity, Flow.

From an energy analytical standpoint, the energy which can support the sediment load of streamflow in suspension is considered only a part of the total energy loss in the streamflow. The concept of potential velocity is introduced to explain the principle of sediment effective power. From the principle of effective power of sediment consideration, an equation has been developed for calculating the variation of the von Karman constant in sediment-laden flow. On this basis, a new classification of moving sediment in an open channel is suggested and a description of the applications to river sedimentation is presented. The variation of von Karman constant in sediment-laden flow, the distinction between wash load and bed-material load, as well as the adequacy of sediment transportation formulas are reviewed. EROSION AND SEDIMENT TRANSPORT IN THE GANGES RIVER BASIN (INDIA),
Jawaharlal Nehru Univ., New Delhi (India). School of Environmental Sciences.
N. Abbas, and V. Subramanian.
Journal of Hydrology, Vol. 69, No. 1, p 173-182, February, 1984. 5 Fig, 3 Tab, 17 Ref.

Descriptors: *Erosion, *Sediments, *India, *Ganges River, Sedimentation, Sediment transport, Sediment load, Denudation, River basins.

Based on the observed erosion rates, the Ganges river system would reach mean sea level in about 4,000,000 yr. However, some of the sub-basins have much higher rates, such as 8,000,000 yr for the Yamuna basin. The basement of the Ganges basin lies below the 6 km thick alluvium. Such a great thickness requies a continuous supply of sediments for at least the past 5,000,000 yr. Thus, the calculated time for basin activity should be corrected for compensating mechanisms such as uplift before the life of a basin can be determined. Annual decrease in basin elevation indicates a rapid process of denudation and such rates have a bearing on rates of shelf sediment accumulation. (Baker-IVI)

SUSPENDED MATTER, MAJOR CATIONS AND DISSOLVED SILICON IN THE ESTUARINE WATERS ON THE MAHANADI RIVER, INDIA,
Utkal Univ., Bhubaneswar (India). Dept. of Geology.
S. B. Ray, M. Mohanti, and B. L. K. Somayajulu.
Journal of Hydrology, Vol. 69, p 183-196, 1984. 5 Fig, 2 Tab, 25 Ref.

Descriptors: *Suspended matter, *Cations, *Dissolved silicon, *Estuaries, *Mahanadi River, *India, Sodium, Potassium, Magnesium, Calcium, Silicon, Trace metals, Sediment transport, Bay of Bengal, Monsoons, Sediment concentration.

A knowledge of suspended and soluble inputs from rivers to the ocean as well as their major- and trace-elemental composition is essential for calculating material balances for various elements and to find out their possible sinks and sources. Results of extensive measurements of suspended matter, major cations Na, K, Mg, Ca and dissolved Si in the waters of the Mahanadi estuary during seven sampling periods between 1977 and 1981 are reported. The particulate concentrations ranged from 0.6 to 596 mg/l during all sampling periods with the highest concentrations occurring in the monsoon season. The mean annual suspended load from the Mahanadi is estimated to be 1.4 x 10 to the 17th power g, almost all of which is monsoonal contribution. Na, K and to a large extent Mg and Ca behave conservatively in the estuary and their annual dissolved fluxes to the Bay of Bengal are: 2.6 x 10 to the 15th power, 7 x 10 to the 14th power, 1.3 x 10 to the 15th power and 4.2 x 10 to the 15th power g, respectively. Si behaves non-conservatively, there is a net removal of 11% of the total annual dissolved Si supply of 3.3 x 10 to the 15th power g to the Bay of Bengal. A major part of this removal occurs during the winter months and appears to be biological. (Murphy-IVI)

CHARACTERISTICS OF SUSPENDED SEDIMENT IN THE SAN JUAN RIVER NEAR BLUFF, UTAH,
Geological Survey, Salt Lake City, UT. Water Resources Div.
K. R. Thompson.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $3.25 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4104, 1982. 21 p, 8 Fig, 3 Tab, 5 Ref.

Descriptors: *Fluvial sediment, *Sediment concentration, Discharge, Sediment load, Sediment sampler, *Colorado River basin, San Juan River basin.

Fluvial-sediment data were collected for the San Juan River near Bluff beginning in 1914 and terminating in 1980. A double-mass curve showed a change in relationship between annual suspended-sediment discharge and annual stream discharge between the water years 1941-44 and 73. Possible causes for these changes in laboratory procedures, and unusually large runoff that occurred in 1941 and 1972. An unknown or unidentified factor may also be involved. The actual reason for this change in relationship may never be fully understood. Navajo Dam apparently has had no significant effect on fluvial sediment at the sampling site. Mean annual suspended sediment discharge in the San Juan River near Bluff was about 25,410,000 tons ranging from 3,234,000 tons in 1978 to 112,400,000 tons in 1941. The use of annual stream discharge to predict annual suspended-sediment discharge at the site will produce poor results because of size and diversity of the basin and the quality of records available. A positive correlation exists between sand concentration and stream discharge at this site, however, considerable variability is evident. This relationship does not exist when stream discharge exceeds 6,000 cubic feet per second. It is recommended that if collection of suspended-sediment records be resumed in this reach of the river an alternative sampling site should be selected and the use of pumping sam-

plers considered because of the remoteness of the area. (USGS)

FORMATION OF PERYLENE IN RECENT SEDIMENTS: KINETIC MODELS,
Indiana Univ. at Bloomington. School of Public and Environmental Affairs.
P. M. Gschwend, P. H. Chen, and R. A. Hites.
Geochimica et Cosmochimica Acta, Vol. 47, No. 12, p 2115-2119, December, 1983. 1 Fig, 1 Tab, 21 Ref. NSF grant OCE-80-05997, DOE grant 80-EV-10449.

Descriptors: *Hydrocarbons, *Sedimentology, *Ponds, *Sediments, *Perylene, Mountain Pond, Maine, Chemical reactions, Kinetics.

Perylene is a pentacyclic aromatic hydrocarbon which has been found in many recent sediments. The concentration of perylene increased regularly with depth in a radiometrically dated sediment core from Mountain Pond, Coburn Mountain, Maine. This high altitude pond is small, shallow and oligotrophic. The location of the pond precludes large interfering inputs of anthropogenic perylene or perylene from weathered rocks. This concentration profile was fit to simple reaction kinetic models which indicate that perylene forms in this core either by a first order reaction characterized by a rate constant of 0.012/yr or by a second order reaction characterized by a rate constant of 0.0013 nmole/g/yr. Such perylene data may be used to judge the constancy, not only of amount but also of kind, of organic matter accumulated. The depth of initial perylene formation may indicate an important reductive horizon in the core while a regularly increasing perylene profile may demonstrate that the anoxic conditions have not varied. Analysis of perylene is not difficult and does not appear to be influenced by sampling or storage artifacts. Thus, perylene could be a very useful geochemical indicator. (Baker-IVI)

MIXING RATES IN SHAGAWA LAKE, MINNESOTA, SEDIMENTS AS DETERMINED FROM 106-RU PROFILES,
Oregon State Univ., Corvallis. School of Oceanography.
J. Van Sickle, W. C. Weimer, and D. P. Larsen.
Geochimica et Cosmochimica Acta, Vol. 47, No. 12, p 2189-2197, December, 1983. 3 Fig, 3 Tab, 36 Ref.

Descriptors: *Lake sediments, *Minnesota, *Shagawa Lake, *Mixing, Radioisotopes, Ruthenium, Sediments, Cesium, Lead, Enrichment, Bioturbation.

Rates of surficial sediment mixing and sediment burial are measured in Shagawa Lake, Minnesota, using radionuclide tracers. Based on Ru-106 profiles in 16 cores, mixing rates average 13 sq cm/yr within the upper 9 cm of sediment. Two other nuclides, Pb-210 and Cs-137, provide further evidence for calculation of mixing rates. In addition, Pb-210 profiles estimate sediment burial rates (about 0.4 cm/yr). Mixing estimates are shown to be fairly insensitive both to uncertainties in sediment burial rates and to temporal patterns of Ru-106 deposition. Results suggest that the deeper sediments in the lake were laid down and buried for some distance during a period of little mixing. Near-surface sediment reworking is likely due to bioturbation. Thus it is reasonable to hypothesize that the benthic fauna, along with its mixing effects, was meager prior to 1900, but has increased greatly since in response to Shagawa Lake's rapid enrichment. (Baker-IVI)

PROCESS OF SEDIMENTATION ON THE SURFACE OF A SALT MARSH,
Delaware Univ., Newark. Coll. of Marine Studies.
R. P. Stumpf.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 5, p 495-508, November, 1983. 4 Fig, 3 Tab, 31 Ref.

Descriptors: *Sedimentation, *Salt marshes, Sediment transport, Sediment size, Holland Glade Marsh, Lewes, Delaware.

An unditched salt marsh-creek drainage basin (Holland Glade Marsh, Lewes, Delaware) has a sedimentation rate of 0.5 cm/year. During normal, storm free conditions, the creek carries negligible amounts of sand and coarse silt. Of the material in the waters flooding the marsh surface, over 80% disappears from the floodwaters within 12 m of the creek. About one-half of the lost material is theoretically too fine to settle, even if flow were not turbulent; however, sediment found on Spartina stems can account for the loss. The quantity of suspended sediment that does reach the back marsh during these normal tides is inadequate to maintain the marsh surface against local sea level rise. This suspended sediment is also much finer than the deposited sediments. Additionally, remote sections of low marsh, sections flooded by only the highest spring tides, have 15-30 cm of highly inorganic marsh muds. This evidence indicates that normal tide flooding does not produce sedimentation in Holland Glade. Study of the effects of two severe storms, of a frequency of once per year, suggests that such storms can deposit sufficient sediment to maintain the marsh. The actual deposition of the fine-grained sediments (fine silt and clay) appears to result primarily from biological trapping rather than from settling. In addition, this study proposes that the total sedimentation on mature marshes results from a balance between tidal and storm sedimentation. Storms will control sediment supply and movement on micro- and meso-tidal marshes, and will have less influence on macro-tidal marshes. (Author's abstract)

IMPROVED NUMERICAL MODEL FOR SEDIMENTATION,
Hochschule der Bundeswehr, Munich (Germany, F.R.). Faculty of Civil Engineering.
W. Bechteler, and W. Schrimpf.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 234-246, March, 1984. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *Mathematical model, *Sedimentation, Mathematical equations, Settling tanks, Dimensional analysis, Wastewater treatment, Diffusion coefficient.

The sedimentation process is an important aspect of the planning and running of many hydraulic and sewage plants. An improved method is developed for the practical dimensioning of horizontal settling tanks. Using this method completed diagrams can be provided to determine the necessary settling lengths for every given removal ratio. The concerned differential equation is solved by a numerical method which can avoid numerical diffusion, therefore predicting more accurately removal ratios in settling basins. Also, concentration profiles and diagrams for dimensioning retarding basins can be computed for different initial and boundary conditions. The flexibility of the model is of practical value with regard to various inlet concentrations and velocity profiles that can be considered. (Murphy-IVI)

SEDIMENT TRANSPORT FORMULA FOR STEEP CHANNELS,
Eidgenoessische Technische Hochschule, Zurich (Switzerland). Versuchsanstalt fuer Wasserbau, Hydrologie und Glaziologie.
G. M. Smart.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 267-276, March, 1984. 4 Fig, 3 Tab, 9 Ref.

Descriptors: *Mathematical equations, *Sediment transport formula, *Steep channels, Sedimentation, Sedimentation rates, Meyer-Peter Mueller equation, Comparison studies, Slopes.

A description is given and results presented of experiments to investigate the sediment capacity of stream flows on flume slopes of up to 20%. A comparison of the results with values predicted by the Meyer-Peter Mueller equation shows that the latter equation seriously underestimates sediment transport capacity on slopes steeper than 3%, mainly because of deficiencies in the form resistance factor. A new equation is proposed, giving the transport capacity for materials with grain sizes larger than 0.4 mm (0.016 in.). The equation is calibrated by both the original Meyer-Peter data and new steep flume experiments and modified to incorporate the effect of nonuniform sediment grain size distributions. With flow depths calculated by the Manning-Strickler equation the new equation still gives excellent estimates of sediment capacity. (Author's abstract)

BED LOAD TRANSPORT OF COARSE NONUNIFORM SEDIMENT,
Regional Engineering Coll., Srinagar (India).
R. L. Misri, R. J. Garde, and K. G. Ranga Raju.
Journal of Hydraulic Engineering, Vol. 110, No. 3, p 312-328, March, 1984. 13 Fig, 1 Tab, 22 Ref.

Descriptors: *Bed load, *Sediment transport, *Coarse sediments, Nonuniform Sediments, Sedimentation, Mathematical models, Mathematical equations, Comparison studies.

A model of bed load movement may be conceived on the assumption that lift is the predominant force influencing the motion of particles smaller than the arithmetic mean size, d sub a, since these particles are hidden in the wakes of the larger particles. Both drag and lift are assumed to affect the motion of the coarser particles. Four coarse uniform materials and 9 sediment mixtures were used as the bed material. There was good agreement only with Einstein's relation when a comparison was made between other bed load relations. A conceptual model for the effect of a particular size of sediment on the transport rates of other sizes of sediment is proposed. The experimental data are analyzed with the dual objectives of assessing the accuracy of existing methods of computation of bed load transport and of proposing a new method of computation. SOURCES AND DISTRIBUTIONS OF SEDIMENTARY ORGANIC MATTER IN THE COLUMBIA RIVER DRAINAGE BASIN, WASHINGTON AND OREGON,
Washington Univ., Seattle. School of Oceanography.
J. I. Hedges, H. J. Turin, and J. R. Ertel.
Limnology and Oceanography, Vol. 29, No. 1, p 35-46, January, 1984. 4 Fig, 3 Tab, 33 Ref. NSF grants OCE 80-23970 and DEB 79-12241.

Descriptors: *Sediments, *Organic matter, *Drainage basins, *Columbia River, *Washington, *Oregon, Basins, Sediment transport, Angiosperms, Gymnosperms, River basins, Lignins, Vegetation.

The Columbia is one of the major river systems of the world with a total drainage basin of 670,000 sq km and a mean annual discharge of 7,200 cu m/s. Nonwoody angiosperm tissues and gymnosperm woods are the major types of vascular plant debris in bottom sediments from 16 sites within the Columbia River and its tributaries. There is a clear relationship between geographic trends in local vegetation and the sedimentary lignin composition of the Columbia River tributaries. In the extensively dammed main river, the vascular plant debris mixtures are more uniform, thus indicating downstream mixing of sedimentary material from reservoir to reservoir. Vascular plant tissues account for an average of a third of the total sedimentary organic matter at the 16 river sites. The remaining organic material has an atomic C:N of 10-15 and a stable carbon isotope composition similar to average land plants. Organic matter in sediments of the Columbia River system is generally enriched in nonwoody angiosperm tissues and lignin-poor or-

ganic matter in comparison to Columbia River derived organic matter in modern marine sediments from the southern Washington continental shelf. (Baker-IVI)

TRANSPORT AND BREAKDOWN OF FECAL PELLETS: BIOLOGICAL AND SEDIMENTOLOGICAL CONSEQUENCES,
Washington Univ., Seattle. School of Oceanography.
G. L. Taghon, A. R. M. Nowell, and P. A. Jumars.
Limnology and Oceanography, Vol. 29, No. 1, p 64-72, January, 1984. 2 Fig, 4 Tab, 36 Ref.

Descriptors: *Benthic environment, *Sediment transport, *Fecal pellets, Benthos, Aquatic life, Benthic fauna, Aquatic animals, Worms, Feces.

Direct and independent measurements were taken of the densities, sizes, and settling velocities of fecal pellets produced by Amphicteis scaphobranchiata, a deposit-feeding polychaete worm. Pellet density was measured by an isosmotic density gradient technique. Densities ranged from 1.086 to 1.282 g/cu cm and settling velocities from 3.03 to 5.94 cm/sec. Pellets were transported as bedload for variable distances. The oldest pellets tested were 6 hr after production. These traveled a median distance of 3.1 m. Freshly egested pellets traveled 9.5 m before disintegrating. While worms would reingest disaggregated pellets, feeding rates correlated positively with pellet age, consistent with earlier findings that this species feeds at a faster rate on energetically more profitable sediment. Substantial interactions among benthic animals, fecal pellets, and the processes of sediment transport are thus verified. (Baker-IVI)

SEDIMENTATION PROBLEMS IN RIVER BASINS,
Uppsala Univ. (Sweden). Naturgeografiska Inst.
A. Sundborg.
Nature and Resources, Vol. 19, No. 2, p 10-21, April-June, 1983. 12 Fig, 1 Tab, 7 Ref.

Descriptors: *Erosion control, *Sedimentation, *River basins, Erosion, Rainfall-runoff relationships, Land use, Agriculture, Sediment transport, Forest management.

In 1975 under the International Hydrological Programme, a project was established to investigate the relationship between sedimentation and erosion on the one hand, and fishing, forestry, wildlife, agriculture, grazing, mining and construction work on the other. The international dimensions of the environmental problems involved are discussed. Man's use of the land can result in accelerated erosion and deposition, river migration, channel-regime changes and many other effects. Problems can occur in three different environments: the source area delivering the material, the river channel system forwarding the load, and the depositional environment, where the particles come to rest. The purpose of taking corrective measures for the control of erosion and sedimentation processes is to reduce or eliminate negative effects. The evaluation of economic losses due to soil erosion and sedimentation problems is a complicated procedure. Actual costs are easy to calculate for specific soil conservation measures and for hydraulic structures in rivers. However, it is more difficult to evaluate costs in economic terms of losses caused by soil deterioration in the upper river basin. International cooperation in soil conservation efforts is needed. (Baker-IVI)

UNSTEADY SEDIMENTATION IN NONUNIFORM RILLS,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
T. E. Croley, II, and G. R. Foster.
Journal of Hydrology, Vol. 70, No. 1-4, p 101-122, 1984. 14 Fig, 1 Tab, 4 Ref.

Descriptors: *Sedimentation, *Runoff, *Rill flow, *Interrill flow, Kinematics, Mathematical models, Overland flow, Hydraulic models, Soil erosion.

The objective of the field study was to measure, very frequently, runoff rate and sediment concentration precisely, until both reached equilibrium. The model being validated assumes a system of parallel ridges and furrows where rill and interrill areas can be precisely defined. The experiments were conducted on a silt-loam soil on a 5% slope. Constant intensity rainfall was applied with a rainfall simulator having impact velocities near those of natural rainfall. The kinematic unsteady overland sedimentation theory of prismatic channels is extended to the experiments by considering both hydraulics and sediment dynamics of rill flow for changing flow geometries of nonuniform and unsteady rill development. The characteristic unimodal concentration peak observed in the experiments and the changing geometry were interpreted in theoretical terms. Overland sedimentation in unsteady nonprismatic rills under uniform rainfall can be described with kinematic models of flow, entrainment and deposition applied to developing flow geometries; this is not possible with sheet-flow models. The hydraulic and sedimentation results are consistent in that each points to the existence of nonprismatic channel developments. The rills develop from deep and narrow, upstream to wide and shallow in the downstream direction, resulting in velocity reduction with increasing flow that is reflected in both the hydraulic analysis and the sedimentation analysis. ACID PRECIPITATION: THINGS ONE CAN DO - THE TUG HILL COMMISSION APPROACH,
New York State Temporary Commission on Tug Hill, Watertown.
D. J. Beevers.
Report, October, 1982. 24 p, 3 Fig, 9 Ref, 1 Append.

Descriptors: *Acid rain, *Public policy, *Public participation, *Environmental policy, Long-term planning, Legislation, Public opinion, Regional planning, Water quality, Economic impact.

Acid precipitation is an international problem requiring more knowledge of its causes and effects, increased public awareness, and national policies to address it. New York's Temporary Tug Hill State Commission, with limited budget, small staff, and only regional jurisdiction, has sought to learn and provide information about acid precipitation and to impact public policy. Only a limited amount of basic research has been conducted in the Tug Hill area, which encompasses 1.3 million acres in 39 towns in portions of four counties. Acid precipitation data collected from four U.S.G.S. monitoring stations (Canton, Stillwater, Hinkley, May's Point) surrounding the area and the National Atmospheric Deposition Program station at Bennett Bridge within the Tug Hill study area, as well as other data, indicate that the area receives a large quantity of highly acidic precipitation. For example, the average lab pH for 22 samples taken at Bennett Bridge between June and December 1980 (the only data available) was 4.09. Some red spruce and red maple die-back may be linked to acid precipitation. The Commission has implemented a variety of activities in response, including use of students to survey acid precipitation, policy statements, research projects on water quality and forest impacts, and design and implementation of a public opinion survey that may lead to additional public awareness, legislative action, and research. Most of these are relatively low-cost activities that similar agencies or other groups could participate in or initiate. (Fazio-Omniplan)

ACID PRECIPITATION AND THE SALMON RIVER SYSTEM, TUG HILL, NEW YORK,
Clarkson Coll. of Technology, Potsdam, NY. Dept. of Civil and Environmental Engineering.
J. V. DePinto, and P. Dentice.
Report, Temporary State Commission on Tug Hill, February, 1977. 49 p, 6 Fig, 6 Tab, 27 Ref, 1 Append.

Descriptors: *Acid rain, *Acid streams, *Chemistry of precipitation, *Acidity, Water sampling, Macroinvertebrates, Areal precipitation, Chemical analysis, Hydrogen ion concentration, Sulfates, Nitrates, Alkalinity, Calcium.

Possibly one of the most serious consequences of this country's tremendous utilization of energy resources could be the acidification of land and water in the northeastern United States as a result of the emission, transport, oxidation and hydrolysis, and deposition of sulfur oxides and nitrogen oxides produced in the consumption of fossil fuels. In accordance with the study's objective of concentrating on Salmon River's water quality, eight sampling sites in the watershed were selected. Precipitation was collected on a bulk basis (wet and dry fallout). The same parameters measured for precipitation samples were analyzed for stream samples, the precipitation on Tug Hill appears to be at least as acidic as the rest of the northeastern United States and in many cases the annual hydrogen ion loading will be higher because of the quantity of precipitation in the area. The chemical and biological water quality of the streams in the Salmon River watershed is quite good and is capable of maintaining a diverse and productive macroinvertebrate community. The system does not appear to have been severely affected by acid rain to date and appears to be in no immediate danger; however, the system may experience long-term deterioration due to continued high acid inputs. Some short-term, event-associated decreases in stream pH were observed, but it is unlikely that these occurrences have cumulatively affected the biota. (Fazio-Omniplan)

SEQUENTIAL SAMPLING AND VARIABILITY OF ACID PRECIPITATION IN HAMPTON, VIRGINIA,
National Aeronautics and Space Administration, Hampton, VA. Langley Research Center.
G. L. Pellett, R. Bustin, and R. C. Harriss.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 33-49, January, 1984. 7 Fig, 3 Tab, 41 Ref.

Descriptors: *Acid rain, *Hampton, *Virginia, Air pollution, Fallout, Air pollution effects, Hydrogen ion concentration, Sulfate, Nitrate, Water pollution, Atmospheric physics, Chemistry of precipitation.

To resolve questions concerning the origin and ecological significance of acid precipitation, major research programs have been initiated in most regions of the world, including the development of nationwide and worldwide precipitation chemistry monitoring networks. Data was taken for a 3-year study of the intraevent volume-resolved variability of pH, sulfate, and nitrate in precipitation at a relatively isolated surburban site in Hampton, Virginia. Rain samples were collected sequentially by amount (approximately 2.7 mm each) from individual events. Rain pH's for $<$ or $=$ 3 mm samples closely fit a monomodal Gaussian distribution with a median of 4.50 and a standard deviation of 0.39. The variability in pH was primarily interevent as opposed to intraevent. The 3-yr volume-weighted

pH was 4.35 + or - 0.02 for 3.16 m collected; annual pH's were 4.31, 4.37, and 4.38, and cumulative H(+) deposition was 141 mg H(+)/sq m. Event-averaged rain pH and meteorological and air quality data were correlated. Low pH was associated with low rainfall volume and rate; rain after several dry days; rains with northeast surface winds; high SO2, NO2 and O3 in the ambient atmosphere; and high, strongly correlated, SO4(2-) and NO3(-) rainwater concentrations. The lowest 3-yr seasonal average pH (4.31) occurred during the summer; values for other seasons were approximately 4.37. It is considered climatologically significant that the volume-weighted H(+) concentrations of sequential samples, for all events, were very well characterized as a function of cumulative rainfall by a power-law fit (exponent = -0.22). Furthermore, as a consequence, event-averaged H(+) deposition varied as the 0.78 power of event volume. While the former result differs from the assumption of linear proportionality sometimes used in the literature, it deviates less from unity than a recent plot of MAP3S data on average SO4(2-) concentration per event, versus rainfall amount. SUMMERTIME STUDY OF ACID DEPOSITION IN THE DETROIT AREA,
General Motors Research Labs., Warren, MI. Environmental Science Dept.
J. M. Dasch, S. H. Cadle, and G. T. Wolff.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 51-60, January, 1984. 9 Fig, 7 Tab, 23 Ref.

Descriptors: *Acid rain, *Detroit, Chemistry of precipitation, Hydrogen ion concentration, Atmospheric physics, Deposition, Warren, Lapeer, Michigan.

A comprehensive acid-deposition measuring (June-September 1981 period) station has been set up at the General Motors Technical Center site in Warren, Michigan. A second station is also being operated at a rural site near Lapeer, Michigan, which is approximately 54 km north of the Warren site. The rain composition was similar at both sites with the pH averaging 4.1 and the SO4(2-)/NO3(-) equivalence ratio averaging 2.1:1. This similarity suggests that local sources, i.e., relatively high emissions near the Warren site, and low emissions near the Lapeer site, have little effect on rain composition. The SO4(2-)/NO3(-) ratio for individual rain events in Warren reflected the SO2/NOx emission ratio in the area from which the event had come. Thus, the highest SO4(2-)/NO3(-) ratios were observed for rains that arrived from the southwesterly direction during this sampling period. Measurements were carried out at both sites to estimate the relative contribution of dry deposition. The ambient particulate was acidic about half the time and basic half the time. The acidity in the particulate was due to acid SO4(2-) and the basicity was due to soil-related materials. Gaseous HNO3 averaged 2.0 microg/cu m while the basic gas, NH3, averaged 0.83 microg/cu m. Based on these measurements, dry deposition of particles and HNO3 contributed less than 10% of the total deposition of acidity during this study period. (Murphy-IVI)

AEROSOL AND PRECIPITATION CHEMISTRY RELATIONSHIPS AT BIG BEND NATIONAL PARK,
Arizona Univ., Tucson. Dept. of Chemistry.
M. R. Derrick, J. L. Moyers, K. A. Yarborough, and M. Warren.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 171-181, January, 1984. 4 Fig, 3 Tab, 14 Ref.

Descriptors: *Aerosols, *Chemistry of precipitation, Air pollution effects, Sulfate, Nitrate, Ammonium, National Parks, Big Bend, Texas, Water pollution sources.

Aerosol chemistry, precipitation and visibility parameters are currently being measured at Big Bend National Park in Texas. This is part of a large-scale air resource evaluation program which the National Park Service is sponsoring in several southwestern national parks and monuments to determine the potential impact of local and distant pollutant sources on the environmental quality within these areas. Analysis of aerosol samples collected at six sites in the Southwest indicates that soil-derived components, organic materials and the acid-base ions of sulfate, nitrate, and ammonium are the major constituents of suspended airborne particulate matter in the remote areas of the arid region. Comparison of particulate matter chemistry and precipitation chemistry data at Big Bend National Park shows consistent features which indicate that the airborne alkaline soil material and NH3 largely neutralize the atmospheric acidic species of H2SO4 and HNO3. This buffering effect of the soil on the precipitation samples indicates that the impact of acidic precipitation on the ecosystem in the region is minimal. Given the similarity of the particulate matter composition and loading at the other monitoring sites, it is suggested that the trace chemical composition of precipitation will be similar in many remote regions of the Southwest. CHEMICAL STRATIFICATION IN THE SENECA/OSWEGO RIVERS (NY),
Upstate Freshwater Inst., Syracuse, NY.
S. W. Effler, J. M. McCarthy, K. W. Simpson, F. J. Unangst, and G. C. Schafran.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, January, 1984. 7 Fig, 4 Tab, 22 Ref.

Descriptors: *Stratification, *Rivers, Seneca River, Oswego River, New York, Chemical reactions, River flow.

The occurrence and characteristics of chemically-based density stratification in portions of the Seneca and Oswego Rivers, downstream of ion-polluted Onondaga Lake, are described for seven different days in the summer and fall of 1978 and 1981, which covered a wide range of river flows. Chemically-based density stratification occurred routinely in the Seneca River downstream of the lake inflow, in response to a continuous chemically-based density difference between the two systems of 0.0015 to 0.0030 g/cu cm. The persistence of the phenomenon, and thus the longitudinal range over which the river stratification occurred, depended on the velocity of river flow and the magnitude of the density gradient that bordered the upper river water and the lower released lake water. The occurrence of chemical stratification in the river had dramatic implications on the corrresponding distribution of dissolved oxygen (DO). The isolation of the organically enriched lake water in the lower layer enhanced the depletion of DO there, which resulted in the development of substantial DO stratification downstream of the discharge from the lake during summer low flow periods. ROLE OF EQUILIBRIUM REACTIONS IN BORE-HOLE WATERS IN THE SKELLEFTEFIELD, NORTHERN SWEDEN,
Umea Univ. (Sweden). Dept. of Inorganic Chemistry.
J. Liden, and S. Sjoberg.
Nordic Hydrology, Vol. 14, No. 3, p 179-192, 1983. 5 Fig, 5 Tab, 26 Ref.

Descriptors: *Boreholes, *Water quality, *Skellefte Field, *Sweden, *Equilibrium reactions, Alkalinity, Acidity, Silicates, Iron, Sulfides, Chemical composition, Water analysis, Chemical reactions.

Measurements of pH and pe (in situ), main ionic constituents, silicic acid and aluminium were made in a series of bore holes in an acid-intermediate volcanite type rock. The bore holes covered the pH interval 6.5-8.6, each with a time invariant solution composition. Field data were used as an experimental test of computerized simulation of weathering reactions by means of equilibrium models. If the solution composition resulting from an equilibration between representative silicate minerals and pure water of P-CO2 corresponding to air is calculated, reasonable agreement is found with field data. These theoretical experiments suggest that in an undisturbed groundwater the primary silicate minerals tend to increase the pH to slightly alkaline values where the dissolved main components reach an irreversible saturation value. However, if the solution composition after an addition of protons is simulated by a stepwise decrease in pH, it is obvious that silicate minerals, including secondary clay minerals, react too slowly to control the ground water by means of any equilibrium reaction. Although a silicate mineral-water equilibrium obviously does not prevail in a system where pH has been decreased by the addition of protons, it is important to realize the strong pH-buffer that has to be crossed in order to convert for example a plagioclase to dissolved ions. As long as these primary silicates remain in the system, the pH will strive towards the alkaline side. (Baker-IVI)

LIMNOLOGICAL STUDY OF SHASTA LAKE, SHASTA COUNTY, CALIFORNIA, WITH EMPHASIS ON THE EFFECTS OF THE 1977 DROUGHT,
Geological Survey, Menlo Park, CA. Water Resources Div.
S. A. Rettig, and G. C. Bortleson.
USGS Water-Resources Investigations Report 82-4081, April, 1983. 61 p, 24 Fig, 16 Tab, 15 Ref.

Descriptors: *Limnology, *Reservoirs, *Water quality, Nutrients, Biological properties, Chemical properties, Physical properties, Lake morphometry, *California, Shasta Lake, *Drought conditions, Hydrologic analysis.

An intensive limnological study of Shasta Lake was made in conjunction with the California Department of Water Resources during the 1977 drought. Water-quality data were collected from March 1977 through September 1978 at six lake stations and four lake tributary stations. Data collected during and after the drought were compared. Lake water quality is described as a function of lake morphometry, climate, hydrology, and reservoir hydraulics. Results indicate Shasta Lake is a warm monomictic lake. Tributary inflow to the lake and outflow through the dam generate density currents which promote mixing at depth and the development of an extensive metalimnion. During the drought, record low lake levels resulted in the exposure of an extensive nearshore sediment zone. Resuspended sediments caused a deterioration of water quality. The most notable effects, in comparison with post-drought conditions, were decreased light penetration, increased dissolved-solids concentration and specific conductance, decreased dissolved-oxygen concentrations, and elevated nutrient levels. A hypolimnetic anoxic condition was observed at the upstream stations of the lake. (USGS)

CONTRIBUTION TO THE PHYSICO-CHEMICAL LIMNOLOGY OF SWARTVLEI,
Rhodes Univ., Grahamstown (South Africa). Inst. of Freshwater Studies.
B. R. Allanson, and C. H. Williams.
Archiv fur Hydrobiologie, Vol. 99, No. 2, p 133-159, January, 1984. 15 Fig, 4 Tab, 37 Ref.

Descriptors: *Limnology, *Rivers, *South Africa, *Swartvlei, *Estuaries, Physical properties, Chemical properties, Lakes, Fulvic acid, Salinity, Meromixis, Wind.

Humate stained rivers caught up in lake basins of Pleistocene origin and connected to sinuous estuaries drain the coastal region of southern Africa in the vicinity of Knysna. The Swartvlei is the largest of these and provides an example of ectogenic

meromixis in South Africa. The lake is of low stability. Wind stress of 7.0 g cm/cm sq erodes the monimolimnion if the input of seawater is restricted by sandbars at the mouth of the estuary. The inflows of peat stained water dominate the light climate of the lake. This implies a high fulvic acid component easily degradable in the lake or estuary. While soluble reactive phosphate remains high in the anoxic monimolimnion, its transfer in significant quantities into the mixolimnion is prevented by the slow rate of erosion of the halocline during periods when the mouth of the estuary is closed. BACTERIAL PRODUCTION AND CARBON CONVERSION BASED ON SALTMARSH PLANT DEBRIS,
R. C. Newell, E. A. S. Linley, and M. I. Lucas.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 4, p 405-419, October, 1983. 3 Fig, 3 Tab, 58 Ref. NIH grant ESO-1908.

Descriptors: *Bacteria, *Carbon cycle, *Salt marshes, Plant debris, Population dynamics, Ciliates, Choanoflagellates, Amoebae, Estuaries, Sediment-water interfaces.

There is a well-defined succession of micro-organisms which colonize powdered leaf debris from Spartina alterniflora and Funcus roemerianus, and aged natural detrital material when incubated in estuarine water at temperatures near to those recorded in the habitat at the time of collection. The natural assemblage of free-living bacteria in estuarine water rapidly enters logarithmic growth, subsequently declining with the increase in numbers of bactivorous microflagelates. These are then replaced by a mixed population of ciliates, choanoflagellates, amoeboid forms and attached bacteria which form part of a complex microbial community associated with particulate debris. The rate of increase of bacterial cells (micron), in both spring and summer experiments ranged from 0.010-0.108/h while estimates of bacterial carbon production ranged from 1.5 to 10.1 microg C/l/h, values which conform well with estimates obtained from natural assemblages of marine bacteria in coastal and estuarine waters elsewhere. Although both the ease of degradation of the detrital substrate and incubation temperature are of importance, enrichment of both powdered Spartina leaf debris and aged natural detritus with inorganic nutrients evidently enhances bacterial production under experimental conditions. In addition, the amount of carbon utilized to sustain bacterial carbon production shows a significant reduction following enrichment with NH4, NO3 or combinations of NO3 + PO4. The bacterial carbon conversion efficiency (microg C incorporated into bacterial production per microg C consumed) x 100, based on powdered Spartina leaves, and aged natural detritus, is thus increased from 9-14%, to as much as 38% in nutrient enriched media. Since NH4, NO3 and PO4 values are generally low in the water column, it seems likely that bacteria achieve a carbon conversion of only 9-14% on natural suspended detrital material, with the possibility of an enhanced conversion of up to 38% occurring at the sediment-water interface where ammonia regeneration occurs. This suggests that suspended bacteria which characterize estuarine waters of salt marsh areas may be responsible for the oxidation of 86-91% of the carbon which enters water column microheterotroph food chains, and are probably implicated in the large CO2 fluxes recently recorded from coastal wetland habitats. (Murphy-IVI)

NUTRIENTS AND PRIMARY PRODUCTION IN PERMANENTLY WELL-MIXED TEMPERATE COASTAL WATERS,
Brest Univ. (France). Station Biologique.
M. V. M. Wafar, P. Le Corre, and J. L. Birrien.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 4, p 431-446, October, 1983. 9 Fig, 1 Tab, 35 Ref.

Descriptors: *Nutrients, *Primary production, *Meromixis, *Coastal waters, Hydrology, Seasonal cycles, France, English channel, Phytoplankton, Hydrologic regime.

Seasonal changes of nutrients and primary production were studied in Morlaix Bay (western English Channel) waters in 1979-1980. This region is characterized by strong tides and consequently the water column remains permanently well-mixed. Owing to this unique hydrological regime, primary production and nutrients follow seasonal cycles different from the classic temperate water cycles. Because of the instability of the water mass, phytoplankton development in spring is slow and attains a maximum only in summer. A minor autumnal primary production peak is absent. The slow development of phytoplankton results in a slow and prolonged utilization of nitrate and phosphate which attain their lowest values only at the end of summer. Predominance of diatoms in the spring phytoplankton results in a rapid utilization of silicon which reaches its lowest concentration as early as May. Ammonium shows a unique cycle in that it accumulates in the water column in spring-summer and is utilized by phytoplankton only when nitrate concentration is low. Nitrite changes show two peaks: a major peak in autumn associated with nitrogen remineralization and a minor peak in spring due to nitrite excretion by phytoplankton. Seasonal development of primary production in these waters is successively limited by silicon, nitrate and total inorganic nitrogen depletion in spring-summer before being eventually limited by light. This is substantiated by the seasonal changes of absolute C-14 assimilation values, solar energy utilization efficiency and assimilation number. Based on these results, it is hypothesized that the ratio between the depth of the euphotic zone and the depth of the water column will indicate whether light or nutrients limit primary productivity in well-mixed temperate waters. CONSERVATIVE BEHAVIOUR OF BORON IN THE TAMAR ESTUARY,
Marine Biological Association of the United Kingdom, Plymouth (England).
M. I. Liddicoat, D. R. Turner, and M. Whitfield.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 4, p 467-472, October, 1983. 3 Fig, 1 Tab, 8 Ref.

Descriptors: *Estuaries, *Boron, *Tamar Estuary, *England, Salinity, Alkalinity.

Thirteen surveys were made of the Tamar Estuary in southwest England during 1980-1982. On each survey surface samples were taken at approximately 3 0/00 salinity intervals between Devil's Point and the point at which the surface salinity fell below 0.5 0/00 (the salt wedge station). Above this point the sampling stations were spaced at 1 km intervals and extended to Weir Head. Each of the samples surveyed showed a conservative (straight line) relationship between boron concentration and salinity. Boron concentrations above the salt-wedge station were small and generally constant. The low concentrations observed in the freshwater end-members suggests that the dissolved boron in the estuary derives almost entirely from seawater. No evidence was found for the systematic addition or removal of boron within the estuary. It is unlikely that serious errors will be introduce into the alkalinity measurements in the Tamar Estuary by calculating the contributions of boron by the sample salinity. (Baker-IVI)

OXYGEN CONSUMPTION BY SEDIMENTS IN A SOUTHERN AFRICAN MANGROVE SWAMP,
Transkei Univ., Umtata (South Africa). Dept. of Zoology.
A. H. Dye.
Estuarine, Coastal and Shelf Science, Vol. 17, No. 4, p 473-478, October, 1983. 3 Fig, 1 Tab, 15 Ref.

Descriptors: *Oxygen requirements, *Sediments, *Mangroves, *Swamp, *South Africa, Mngazana estuary, Estuaries, Biological oxygen demand, Chemical oxygen demand.

Total, chemical and biological oxygen demand of intertidal sediment cores from 12 stations in a mangrove swamp in southern Africa were measured under mean temperature and salinity conditions. In addition to measuring oxygen removed from water overlying cores, the uptake of oxygen from air overlying sealed cores was also determined. Total oxygen consumption ranged from 2.9 to 37.0 ml O2/sq m/h in water and from 22.1 to 81.6 ml O2/sq m/h in air. Chemical oxygen demand usually equalled or exceeded the total, underlining problems in the measurement of this parameter. Since oxygen is not present below a few millimeters in the sediment, it is concluded that oxygen diffusing from the overlying water or air is rapidly utilized at the surface and its uptake rate does not give any measure of metabolic activity deeper down. The oxygen content of the overlying water present during high tide may drop to relatively low levels due to this demand. (Author's abstract)

BEHAVIOUR OF THE RARE EARTH ELEMENTS DURING MIXING OF RIVER AND SEA WATERS,
Cambridge Univ. (England). Dept. of Earth Sciences.
J. Hoyle, H. Elderfield, A. Gledhill, and M. Greaves.
Geochimica et Cosmochimica Acta, Vol. 48, No. 1, p 143-149, January, 1984. 6 Fig, 2 Tab, 20 Ref.

Descriptors: *Rare earth elements, *Rivers, *Seawater, *Mixing, *Water of Luce, *Scotland, Neodymium, Estuarine environment, Estuaries.

Rare earth element concentrations were measured in organic rich water from the Water of Luce, a river on the south-west corner of Scotland, and coastal sea water. Concentrations of about 350 to 1850 pmol/kg Nd were found in the water of the river and 45 to 350 pmol/kg Nd in Luce Bay. These concentrations were related to the presence of particles, with 30-60% of the rare earth elements (REE) associated with greater than 0.4-0.7 micrometer particles and to riverine Fe concentrations. REE fractionation occurred in the river water. The submicrometer river water was heavy with REE enrichment whereas the coarser fraction had a more shale-like REE pattern. Lab studies indicate that REE in organic-rich water are chiefly associated with Fe-organic matter colloids which flocculate during estuarine mixing. Preferential removal of heavy REE relative to light REE (95 to 60%) occurs, but no Ce anomaly is developed. In contrast, no REE removal occurs during estuarine mixing with organic-poor river water. EVALUATION OF A SEQUENTIAL EXTRACTION SCHEME TO STUDY ASSOCIATIONS OF TRACE ELEMENTS IN ESTUARINE AND OCEANIC SEDIMENTS,
Southampton Univ. (England). Dept. of Oceanography.
W. A. Maher.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 3, p 339-344, March, 1984. 2 Fig, 3 Tab, 7 Ref.

Descriptors: *Estuarine environment, *Sediments, *Trace elements, Estuaries, Sea water, Manganese, Iron, Aluminum, Organic compounds, Calcium carbonate, Carbonates, Silicon, Leaching.

Three deep sea sediments and three estuarine sediments were examined. To evaluate the optimum times for leaching the carbonate phase, sediment samples were first leached for one hour with 1 M magnesium chloride (pH 7), and then further leached with 1 M sodium acetate (pH 5), adjusted with acetic acid. The calcium concentrations were measured in the centrifuged supernatants at different time intervals. For all sediments, dissolution of calcium was complete within five hours. To evaluate the optimum time for reducing and dissolving iron and manganese oxides, sediment samples previously leached for exchangeable metals and carbonates were leached with the hydroxylamine hydrochloride-acetic acid reagent, and the iron content measured in the centrifuged supernatants at different time intervals. To assess the selectivity of each fraction, aluminium, calcium, iron, manganese

and silicon were determined in each extract. A sequential extraction scheme was found to be suitable for partitioning estuarine and oceanic sediments containing low organic carbon contents into major geochemical fractions. Due to the interaction of iron-manganese oxide phases and organic material, the selective dissolution of these fractions in organic rich sediments is not possible using the scheme outlined. CHESAPEAKE BAY NUTRIENT AND PLANKTON DYNAMICS. 2. SOURCES AND SINKS OF NITRITE,
Harvard Univ., Cambridge, MA. Museum of Comparative Zoology.
J. M. McCarthy, W. Kaplan, and J. L. Nevins.
Limnology and Oceanography, Vol. 29, No. 1, p 84-98, January, 1984. 8 Fig, 3 Tab, 41 Ref.

Descriptors: *Bays, *Nutrients, *Nitrites, *Chesapeake Bay, Water pollution sources, Nitrates, Ammonia, York River, Chemical analysis, Estuaries.

A combination of N-13 tracer techniques and assays of the concentrations of chemical constituents were used to investigate the transformations of inorganic nitrogenous nutrients that can lead to the frequently observed high levels of nitrite in the Chesapeake Bay and York River. Uptake and remineralization of NH4(+) in the York River during destratification followed a diel cycle. Nitrification was not as closely coupled to the light regime. The primary source of N2O and NO2(-) appeared to be in the water rather than in the sediments. The N-15 data indicated that oxidized N could be formed in the water of the bay when physical events caused the mixing of NH4(+)-rich bottom water with more oxygenated surface layers. Also, the NO3(-) was reduced to NH4(+) at unexpectedly rapid rates in well oxygenated surface waters. The magnitude and duration of high concentrations of N2O and NO2(-) in these estuarine waters during mixing events might be expected to increase if anthropogenic loading of nutrients causes anoxic conditions in the bay to become more widespread. (Baker-IVI)

ABOVEGROUND AND BELOWGROUND PRIMARY PRODUCTION DYNAMICS OF TWO DELAWARE BAY TIDAL MARSHES,
Delaware Univ., Newark. Coll. of Marine Studies.
C. T. Roman, and F. C. Daiber.
Bulletin of the Torrey Botanical Club, Vol. III, No. 1, p 34-41, January-March, 1984. 3 Fig, 5 Tab, 29 Ref.

Descriptors: *Primary productivity, *Aboveground, *Belowground, *Delaware Bay, *Tidal marshes, Angiosperms, Carbon cycle, Nitrogen cycle, Canary Creek, Blackbird Creek.

Aboveground and belowground net primary productivity estimates of the dominant angiosperm from two tidal marshes along the Delaware Bay estuary including ash, carbon and nitrogen content were determined. Annual net aboveground production was determined by the peak live standing crop method and the Smalley method. Aerial production of tall Spartina alterniflora Loisel. at the Canary Creek salt marsh, employing the Smalley technique was 1487 g/sq m/yr, while production of short S. alterniflora, S. patens (Ait.) Muhl. and Distichlis spicata (L.) Greene was, 654 g/sq m/yr, 1147 g/sq m/yr, and 785 g/sq m/yr, respectively. At the brackish water Blackbird Creek marsh, Phragmites australis (Cav.) Trin. had the highest aboveground production (2940 g/sq m/yr), followed by S. patens (1089 g/sq m/yr) and short S. alterniflora (916 g/sq m/yr). Belowground primary production was determined by the annual increment (max-min) method, with respective estimates of 6.5 kg/sq/m/yr, 5.0 kg/sq m/yr, and 3.3 kg/sq m/yr, for tall S. alterniflora, short S. alterniflora and S. patens, at the Canary Creek marsh. Belowground estimates at the Blackbird Creek marsh were within this range. (Murphy-IVI)

TRANSPORT AND DISTRIBUTION OF NUTRIENTS IN THE LOXAHATCHEE RIVER ESTUARY, SOUTHEASTERN FLORIDA, 1979-81,
Malawi Water Resources Div., Lilongwe.
B. F. McPherson, and W. H. Sonntag.
Water Resources Bulletin, Vol. 20, No. 1, p 27-34, February, 1984. 4 Fig, 4 Tab, 16 Ref.

Descriptors: *Estuaries, *Nutrients, *Loxahatchee River Estuary, *Florida, Nitrogen, Phosphorus, Organic carbon, Mixing, Seawater, Storm runoff, Tidal flushing, Salinity, Tropical cyclones.

Concentrations of total nitrogen, total phosphorus, and total organic carbon in the Loxahatchee River estuary decreased with increasing salinity in a manner indicating that mixing and dilution of freshwater by seawater was the primary process controlling the downstream concentrations of nutrients. Most of the nutrients in the surface freshwater inflows entered the estuary from five major tributaries; however, about 10% of the total nitrogen and 32% of the total phosphorus were from urban stormwater runoff. The input of nutrients was highly seasonal and storm related. During a 61-day period of above average rainfall that included Tropical Storm Dennis, the major tributaries discharged 2.7 metric tons of total phosphorus, 75 metric tons of total nitrogen, and 1,000 metric tons of organic carbon to the estuary. This period accounted for more than half of the total nutrient load from the major tributaries during the 1981 water year (October 1, 1980, through September 30, 1981). Inorganic phosphorus and nitrogen increased relative to total phosphorus and nitrogen during storm runoff. Nutrient yield from the basin, expressed as grams per square meter of basin area, was relatively low. However, because the basin area (544 sq km) is large compared with the volume of the estuary, the basin might be expected to contribute significantly to estuarine enrichment were if not for tidal flushing. Approximately 60% of the total volume of the estuary is flushed on each tide. Because the estuary is well flushed, it probably has a large tolerance for nutrient loading. (Author's abstract)

PLANT GROWTH ON EXPERIMENTAL ISLAND BEDS AND NITROGEN UPTAKE FROM SURROUNDING WATER,
Papua New Guinea Univ., Port Moresby. Dept. of History.
D. E. Vasey.
Agriculture, Ecosystems and Environment, Vol. 10, No. 1, p 15-22, August, 1983. 1 Tab, 24 Ref.

Descriptors: *Nitrogen, *Island beds, *Raised beds, *Plant growth, Cultivation, Wetlands, Algae, Eutrophication.

An ancient method of preparing wetlands for cultivation consists of moving earth to form raised planting surfaces which are surrounded by water for all or part of the year. Revivials of the system are aimed at providing insights into prehistory, restoring traditional intensive methods, and adapting the system to modern agriculiural technology and commercial economies. Experimentation was begun in 1980 to determine the paths by which combined nitrogen present in the surrounding channels might become available to crops on the beds. The potential contribution of combined N from the water to crops on island beds and raised fields could be substantial, if conditions favor biological N-fixation and appropriate means of transferring organic matter and combined N are developed. Total N reached much higher levels in artificial ponds exposed to sunlight than in completely shaded ponds, and yet Para grass, planted in pots that allowed the roots to extend through to the ponds, made significantly more growth in the shaded ponds than in the sunny ponds. The test crop could not complete effectively for N with algae, and N in surrounding eutrophic bodies of water is readily available to crops on island beds only if the crop roots reach channel sediments, or organic matter is transferred form the channels to the beds. DEVELOPMENT OF BENTHIC COMMUNITIES ON NEW BREAKWATERS,
Institute of Biology of the Southern Seas, Sevastopol (USSR).
O. G. Mironov, N. Yu. Milovodova, and I. M. Tsymbal.
Hydrobiological Journal, Vol. 19, No. 1, p 49-53, 1983. 2 Fig, 1 Tab, 5 Ref.

Descriptors: *Benthic environment, *Piers, Breakwaters, Hydrobiology, Black Sea, Algae growth, Substrates, Stones.

Quantitative characteristics are presented for phyto- and zoobenthos populating newly erected pier structures. It is established that the phyto- and zoobenthos are similar in qualitative and quantitative respect to natural ones. Biocenoses of pier structures differ in a series of specific peculiarities connected with the period of their formation. The complex of animal forms populating the stones in the breakwaters which have been described is quantitatively similar to that found on the natural stones of Novorossiysk Bay, but less varied than that on the stones of the open parts of the Caucasian and Crimean coastlines. Accordingly, even during the first years of their existence, manmade stone marine structures become covered with a relatively thick biofilter resembling the natural biofilter of natural stone substrates. HYDROGEOLOGY FOR LAND-USE PLANNING: THE PETERS CREEK AREA, MUNICIPALITY OF ANCHORAGE, ALASAKA,
Geological Survey, Anchorage, AK. Water Resources Div.
J. O. Brunett, and M. Lee.
USGS Water-Resources Investigations Report 82-4120, 1982. 6 p, 14 Fig, 2 Tab, 23 Ref.

Descriptors: *Groundwater, *Geohydrologic units, Groundwater, Wetlands, Streamflow, Drainage, Erosion, Water quality, Water pollution, Sewage disposal, Water supply, Landslope, *Land-use planning, *Alaska, Anchorage, Peters Creek, Chugach Mountains, Knik Arm, Fire Lake, Chugiah, Birchwood, Eklutna.

Wells currently provide all water supplies in the area. Most wells obtain enough water for individual household needs from unconsolidated, principally glacial and glacioalluvial deposits. In some places, however, wells must be drilled into the underlying bedrock to obtain adequate supplies. It may be possible to develop small community supplies--for individual trailer courts or subdivisions--in areas where yields of 20 gallons per minute or greater are reported for private, domestic wells. Peters Creek is a potential source of surface-water

supply, but it would have to be treated to remove glacial silt during summer months. The chemical quality of both ground water and surface water in the area in generally acceptable for most uses. Foundation and excavation conditions, the potential for water pollution from onsite disposal of wastewater through septic tank systems, and the suitability of specific areas for certain types of development may be affected by the following factors: wetlands and areas of shallow ground water underlie about 30 percent of the study area; landslope exceeds 20 percent in about a third of the area; areas of fine-grained, low-permeability sediments are present locally; bedrock is within 25 feet of the land surface in about a third of the area. EVAPORATION REDUCTION: SUMMARY OF LONG-TERM TANK STUDIES,
Agricultural Research Service, Boise, ID. Northwest Watershed Research Center.
K. R. Cooley.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 1, p 89-98, March, 1983. 1 Fig, 4 Tab, 18 Ref.

Descriptors: *Evaporation, *Evaporation control, Floating covers, Cost analysis, Cost-benefit analysis, Reservoir evaporation, Water conservation.

Conserving water contained in existing storage facilities, is in some situations, the most economical means of providing adequate water supplies. A review of evaporation reduction studies indicated that shades suspended above a water surface and floating covers on a water surface gave best results. Of the two, floating covers were most practical. Field tests using floating covers of foamed wax blocks, continuous wax, and foamed rubber reduced evaporation losses 36%-84% over an 8 yr period. Based on the amount of the water saved and the cost of materials used, the continuous wax covers provided the lowest cost water at $0.08 to $0.13/1,000 L/yr, followed by foamed rubber and foamed wax blocks at $0.17 and $0.18 per 1,000 L/yr, respectively. However, evaporation reduction efficiency of the continuous wax covers began to decrease after a few years of exposure, while the foamed rubber and foamed wax blocks showed no signs of deterioration. Long-term durability, efficiency, and climatic range of usability should be considered along with costs when determining the most practical cover to use. (Murphy-IVI)

GUIDELINES FOR CLOUD SEEDING TO AUGMENT PRECIPITATION.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 1, p 111-182, March, 1983. 14 Fig, 1 Tab, 94 Ref, 2 Append.

Descriptors: *Cloud seeding, *Weather modification, *Water resources development, Environmental effects, Social aspects, Economic aspects, Feasibility, Legal aspects, Cost-benefit analysis.

The guidelines for implementing weather modification are intended to provide water resources managers with information and references that they may need to make a decision on the use of weather modification to augment available water supplies. The sections cover a variety of aspects of weather modification including the social, legal, environmental and economic issues as well as the scientific basis. The scientific basis for cloud seeding to augment precipitation rests on the assumptions that natural cloud precipitation can be increased (static seeding) or that cloud development can be enhanced (dynamic seeding) to produce bigger clouds. The augmentation possible is fractional, in the range of 5-20%; this much additional over the farm belt would be helpful to agriculture, and the addition over mountainous terrain would benefit the hydroelectric power industry and irrigation interests. The technical details of various devices for producing artificial nuclei, and the various methods for distributing the artificial nuclei through cloud masses are described in detail. The type of generating system employed and its mode of operation depends upon the type of cloud systems that are to be treated. Initial steps toward implementing a seeding program include consideration of the need for augmented precipitation, how it would be used and alternative approaches. A feasibility study is desirable and should include a clear statement of all objectives of the proposed project. A design study should include review of objectives vs. time, statements of program goals, alternative plans, and longer term aspects. The risks and costs must be estimated as thoroughly as are the benefits. (Moore-IVI)

NITROGEN AVAILABILITY FROM POTATO-PROCESSING WASTEWATER FOR GROWING CORN,
Agricultural Research Service, Kimberly, ID. Snake River Conservation Research Center.
J. H. Smith, and C. W. Hayden.
Journal of Environmental Quality, Vol. 13, No. 1, p 151-156, 1984. 10 Tab, 11 Ref.

Descriptors: *Nitrogen, *Potato-processing wastewater, *Corn, Sprinkler irrigation, Irrigation effects, Wastewater disposal, Water reuse, Corn yield, Wastewater irrigation, Caldwell, Idaho.

Irrigating with food-processing wastewater for growing crops is an established practice used by a large segment of the food processing industry. In many existing systems, emphasis has been placed on disposing of wastewater with maximum applications of both the wastewater and included plant nutrients. A line source sprinkler was used to irrigate corn (Zea mays L.) plots with potato (Solanum tuberosum L.)-processing wastewater in 1979, 1980, and 1981. Nitrogen applications ranged from about 4 to 600 kg/ha. Corn yields were measured for each row, the grain and stalks were analyzed for total N, and N uptake was calculated. The plots were split by years, one-third of the area was fertilized with wastewater 3 y, one-third 2 y, and one-third 1 y. This allowed evaluation of current and residual value of wastewater fertilization. Corn responded well to wastewater fertilization, with N applications in the wastewater increasing corn yields with increasing increments of N up to about 200 to 250 kg/ha annually, and corn grain yields ranged up to about 12 Mg/ha. Yield comparisons were made with plots fertilized with ammonium nitrate fertilizer. We determined that potato-processing wastewater N was almost equal to ammonium nitrate N for growing corn. Wastewater applications that will apply approximately 200 to 250 kg N/ha annually should be optimum for growing corn on this soil. Wastewater N from potato processing has good residual and carry-over for 1 y but under conditions of this experiment did not carry over for more than 1 y. Whether the excess N was lost from denitrification or leaching was not determined. (Murphy-IVI)

LAND CONSOLIDATION IN IRRIGATION PROJECTS,
International Bank for Reconstruction and Development, Washington, DC. East Asian and Pacific Projects Dept.
H. L. Plusquellec.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 1, p 99-110, March, 1983. 4 Fig, 2 Ref.

Descriptors: *Irrigation programs, *Rational layout, *Water distribution, *Land consolidation, Surface irrigation, Sprinkler irrigation, Irrigation efficiency, Crop yield, Farming, Developing countries.

A model for land consolidation and the layout of irrigation systems was developed in Morocco about 20 yr ago and has been used widely there ever since. Known as the 'rational layout' scheme, this approach facilitates modern farming activities and rotational water distribution in areas with diversified agriculture and small land parcels. Rational layout represents a fusion of two other approaches to irrigation layout which were tested individually with less success: (1) an agriculturist's approach emphasizing modern farming principles, particularly collective plowing; and (2) an engineering approach which provides a permanent consolidated on-farm irrigation network, including irrigation ditches, drainage channels and farm roads. The rational layout scheme is unique in dealing with the various factors that must be considered in regrouping separate small plots into consolidated areas for irrigation. These include irregular plot size, surface or sprinkler irrigation systems, crop diversification, crop rotation, and agricultural mechanization. Areas using this system have shown increased irrigation efficiency, higher yields and cropping intensity, and increased use of modern agricultural practice. (Author's abstract)

IRRIGATION WATER DELIVERY PERFORMANCE,
Agricultural Research Service, Phoenix, AZ. Water Conservation Lab.
A. J. Clemmens, and A. R. Dedrick.
Journal of Irrigation and Drainage Engineering, Vol. 110, No. 1, p 1-13, March, 1984. 5 Fig, 1 Tab, 15 Ref.

Descriptors: *Irrigation water, *Water delivery, *Colorado River Indian Reservation, *LaPaz county, *Arizona, Water conveyance, Water use, Flow rate, Variability.

Data were collected from sites on the Colorado River Indian Reservation, LaPaz county, Arizona, in 1980 and 1981. Twenty delivery sites within the irrigation district were monitored in order to determine the amount of variability in flow rate during each water delivery. The coefficient of variation (CV) of instantaneous (1/2 hour) flow rate values averaged for each turnout ranged from 0.04-0.29. CV was related to the location of the site within the delivery system. Time of year, flow rate, and crops grown did not appear to affect CV. On-farm water use is affected by the level of delivery flexi-

bility and the uniformity of water deliveries. Upgrading of farm irrigation systems may require improvements in delivery flexibility and uniformity. Increasing the delivery flexibility may result in less uniform deliveries, which may also reduce the operational conveyance efficiency of the delivery system unless the system is also upgraded. Delivery system performance can be improved by such structural measures as the addition of measuring devices, canal control devices, improved turnout sturctures, or reservoirs. Nonstructural (management) changes can have an equally important effect. A change of attitude is usually required by both water users and district personnel if effective improvement in system performance is to be attained. (Moore-IVI)

SUITABILITY OF REDUCED PRESSURE CENTER-PIVOTS,
Nebraska Univ., Lincoln. Dept. of Agricultural Engineering.
J. R. Gilley.
Journal of Irrigation and Drainage Engineering, Vol. 110, No. 1, p 22-34, March, 1984. 7 Fig, 5 Tab, 14 Ref.

Descriptors: *Irrigation, *Center pivot irrigation, *Reduced pressure, *Runoff, Soil properties, Sprinkler irrigation, Irrigation depth.

Reduced pressure center-pivot systems, using spray nozzles or low-pressure impact sprinklers, are becoming popular and many existing high pressure systems are being retrofitted with reduced pressure devices. Reduced pressure systems can be operated at pivot pressures approaching 130-200 kPa, resulting in considerable energy savings. Selection criteria are developed for reduced pressure center-pivot irrigation systems. The combined effects of the application rate characteristics of center-pivot irrigation systems and the soil intake family curves were analyzed to determine the maximum depth of water which could be applied per irrigation for various types of soils and sprinkler packages. The irrigation depths are used to determine guidelines for proper selection of reduced pressure center-pivot systems. The results can be used as a general guide to determine if a particular system may have a runoff problem under a given situation. The maximum irrigation depth which may be applied without any potential runoff may be too small for some systems to provide an acceptable irrigation amount, and therefore should not be used in that particular location. SURVEY OF STATE WATER CONSERVATION PROGRAMS IN THE U.S.,
Georgia Inst. of Tech., Atlanta. Coll. of Architecture.
T. N. Debo, and N. Rogers.
Water Resources Bulletin, Vol. 20, No. 1, p 67-74, February, 1984. 1 Fig, 1 Tab, 1 Append.

Descriptors: *Water conservation, *State jurisdiction, Legal aspects, Education, Drought.

Adequate water supplies are critical to the maintenance of a community's health and economic well-being. As the demand grows and communities actively compete with one another for a limited water supply, states are being called upon to help solve the problem. One solution being used in many areas is the development and implementation of a water conservation program. Using a mailed survey, state water conservation programs and some of the characteristics of the different programs were documented. Responses to the nationwide survey were obtained from all 50 states. The specific water conservation program elements on which information was received from the survey included laws and restricted use, community assistance, education, research, and other services. Eighteen of the 50 states indicated in the survey that they had some level of a water conservation program in operation. The need for state level programs was expressed by at least 36 states. Eighteen states indicated they have programs under development or study at the time of the survey. In addition to the states that are developing or have water conservation programs, seven states have emergency or drought water conservation programs. Seven other states have plans for emergency programs in addition to their operating programs. The 36 states which have either established a water conservation program, are developing programs, or are studying the issue should act as valuable resources for one another and the remaining states to meet the water supply needs of the future. INTRODUCING INFILTRATING IRRIGATION TECHNOLOGY.
Irrigation Journal, Vol. 33, No. 3, p 14-16, May/June, 1983. 4 Fig.

Descriptors: *Water supply development, *Irrigation, *Saline water, Infiltrating Irrigation Technology, Irrigation plans, Water supply.

An infiltrating irrigation technology (IIT) device is presented which prevents salt damage to soil. The IIT is designed to let the irrigation water abide in the soil by using the absorbing nature of soil. According to the IIT theory, the salt contained in irrigation water naturally concentrates around the emitter. Therefore, the moistened area within the soil can be automatically receiving desalted water. In tests where irrigation was performed with saline water incessantly for 11 days using IIT under a speed of 0.62 cc/min (about 990 cc/day), the IIT proved to be a simple structure capable of using water which had not been applicable as irrigation water prior to that time. 4. WATER QUANTITY MANAGEMENT AND CONTROL

4A. Control Of Water On The Surface

REPORT OF THE RIVER MASTER OF THE DELAWARE RIVER FOR THE PERIOD DECEMBER 1, 1981 - NOVEMBER 30, 1982,
Geological Survey, Trenton, NJ. Water Resources Div.
F. T. Schaefer, and R. E. Fish.
USGS Open-File Report 83-538, 1982. 91 p, 7 Fig, 19 Tab, 2 Ref.

Descriptors: *Delaware River, Diversion, Release, *Water management, Drought, *Reservoir yield, *Regulation, Supply, Inter-basin transfers, *River Master Report.

The Amended Decree of the Supreme Court of the United States in 1954 established the position of Delaware River Master to administer provisions of the decree relative to diversions from the Delaware by the City of New York and the State of New Jersey, and releases from reservoirs of the City of New York designed to maintain stipulated rates of flow in the river. Reports to the Court, not less frequently than annually, with copies to the Governors and the Mayor, were stipulated. Water-supply conditions at the beginning of the year were under a status of emergency resulting from drought, which had been declared by the Delaware River Basin Commission. With the filling of the reservoirs, the emergency was lifted April 27. Runoff of Delaware River at Montague, New Jersey, was 19 percent below median during the year as compared to 28 percent below median the previous year. By November, with reservoir storage again declining, reductions in both diversions and releases were imposed. To conserve supplies, reductions were effected on November 13 limiting New York City diversions at 680 mgd and New Jersey to 85 mgd, and the required discharge at Montague was targeted at 1,655 cfs. Water quality of the Delaware River and Estuary was monitored on a continuous basis at six sites for most of the year and on a monthly basis at ten sites to accurately locate the salt front. Highest chloride concentration observed at the Chester, PA, site was 870 mg/l November 4. (USGS)

TILLAGE SYSTEM AND RESIDUE COVER EFFECTS ON INFILTRATION IN NORTHWESTERN CORN BELT SOILS,
Agricultural Research Service, Morris, MN.
M. J. Lindstron, W. B. Voorhees, and C. A. Onstad.
Journal of Soil and Water Conservation, Vol. 39, No. 1, p 64-68, January-February, 1984. 4 Fig, 2 Tab, 19 Ref.

Descriptors: *Tillage, *Residue cover, *Infiltration, Rainfall-runoff relationships, Agricultural runoff, Runoff rates, Runoff volume, Soil physical properties, Hydraulic conductivity, Rainfall energy.

Some reports indicate that tillage systems leaving residue on the soil surface will reduce runoff and erosion. Other reports, however, indicate that surface residue does not always reduce runoff, particularly in no-till systems. The conflict in these reports indicates that other factors, in combination with surface residue, must influence infiltration rate and runoff potential. Simulated rainfall trials were conducted in wheel-tracked and nonwheel-tracked interrows for conventional, reduced, and no-till cropping systems immediately after planting during the first and tenth years of continuous corn. Results showed that (a) tractor wheel-traced interrows were vulnerable to runoff regardless of tillage system and (b) infiltration declined after runoff started. Runoff occurred quickly on the no-till, nonwheel-tracked interrow, indicating the presence of some infiltration restricting factor(s). Bulk density, penetrometer resistance, saturated hydraulic conductivity, and pore-size distribution were measured during the third crop year of continuous corn to determine soil physical properties that developed with tillage systems and the effect these properties had on infiltration. The no-till treatment-modified in this trial by cultivation during the previous growing season to form ridges - was characterized by a higher bulk density, greater penetrometer resistance, reduced saturated hydraulic conductivity, and a lower volume of macropores. The no-till treatment exhibited reduced infiltration. Surface crop residue effectively increased the rainfall energy required to start runoff under the reduced tillage system, but residue had no effect when soil surface conditions (no-till and wheel-tracked interrows) had developed that restricted water movement into the soil. PRACTICAL APPLICATIONS OF A SHADING MATERIAL FOR MACROPHYTE CONTROL IN WATERCOURSES,
Freshwater Biological Association, Wareham (England). River Lab.
F. H. Dawson, and H. B. Hallows.
Aquatic Botany, Vol. 17, No. 3/4, p 301-308, December, 1983. 2 Fig, 1 Tab, 10 Ref.

Descriptors: *Rooted aquatic plants, *Aquatic weed control, *Shading, Macrophytes, Ranunculus, Nasturtium, Apium, Elodea, Sparganuim, Phragmites.

Typar, a light-weight gas-permeable opaque spunbonded polypropylene was used for the control of rooted macrophytes in flowing waters in areas

normally subject to mechanical control. The material has a relatively high tensile strength and resistance to mechanical penetration; this black-colored light-weight grade reduced the passage of light by approximately 70%. Submerged macrophytes were more rapidly controlled than emergent ones, primarily because the build up of detritus on submersed material reduced the light penetration. The period required for control varied: Ranunculus penicillatus var. calcareus, 5-8 weeks; Nasturtium officinale and Apium nodiflorum, 6-9 weeks; Elodea spp., Sparganium erectum and Phragmites australis, 12 weeks. Shorter periods give partial control whereas extended periods require macrophytes to reinvade controlled sites. This technique, i.e., the planned cycle of movement of material during the plant growing season, is considered economically competitive with other methods and could be applied to a wide variety of sites currently being managed by techniques which stress the biological system. Shaded material may be aesthetically displeasing but it does avoid excessive or rapid stress typical of mechanical control and it does not contaminate the stream system. It is local in action, reliable in effect and can give firm control of rooted macrophytes without eradicating them. Shading material may be particularly suitable for sensitive areas such as nature preserves and special interest sites and also for areas in need of constant local plant control, such as gaging weirs and in fisheries. ARTIFICIAL RECHARGE IN THE NORTHERN PART OF CHINO GROUND-WATER BASIN, UPPER SANTA ANA VALLEY, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
J. H. Koehler.
USGS Water-Resources Investigations Report 82-4122, June, 1983. 23 p, 7 Fig, 4 Tab, 6 Ref.

Descriptors: Water resources, Hydrology, Geology, Drillers' logs, Precipitation, *Groundwater, *Artificial recharge, Infiltration rate, *California, Chino basin.

This study was made to help management design and implement a recharge-recapture system for State Water Project water in Chino Basin. Nine test holes were drilled in the study area. Analyses of data from these test holes and drillers' logs of water wells indicate the presence of clay deposits. The clay deposits cannot be correlated between holes which indicates that they are in the form of discontinuous beds or lenses. The existence and location of two ground-water barriers (Barrier 'J' and Red Hill Barrier) have been postulated in previous reports. Water-level data indicate that Barrier 'J' is probably not effectively stopping the movement of ground water. Data are insufficient to determine the effectiveness of the Red Hill barrier. Five existing recharge facilities in the study area were previously constructed to control floodflow. Infiltration tests were conducted at three of the facilities, and results of these tests indicate infiltration rates of 2.6 feet per day at Day Creek, 2.0 feet per day at East Etiwanda, and 1.3 feet per day at San Sevaine. A total of about 9,000 acre-feet of State Water Project water was recharged between June 1980 and July 1981. Rising water levels in wells indicate that recharge water is percolating down to the water table. (USGS)

GROUNDWATER MANAGEMENT PLANNING,
Disko (M.) Associates, Union, NJ.
M. Disko, D. Nusser, and E. Doheny.
Report, April 1978. 410 p, 66 Fig, 40 Tab.

Descriptors: *Groundwater management, *Potable water, *Permeability, *Water rights, *Groundwater inventory, Tourism, Drinking water, Domestic water, Surface-groundwater relations, Pumping tests, Legal aspects, Subsurface water, Recreation.

All of the potable water consumed in Orange County, New Jersey comes from groundwater. Increasing population and industrial development throughout the county, accompanied by the inevitable lowering of surface water quality, make the groundwater supplies all the more valuable. Industrial manufacturing and agriculture is at present of relatively minor importance in the county, while the largest influx of revenues is provided by the seasonal tourist industry, which is geared to bathers, boaters, fishermen and other sports enthusiasts. Ocean County is drained principally by east and southwest flowing consequent streams of the coastal drainage area. The streams exhibit an essentially uniform dentritic drainage pattern due to the relatively uniform nature of the underlying material. Calculations of permeability were performed for wells in the 208 Planning Area where the necessary pumping test data were available. Permeabilities ranged from 105 to 4,363 gpd/sq. ft., with an average value of approximately 1,900 gpd/sq. ft. This is somewhat higher than values determined in past studies. New Jersey law provides for the diversion of subsurface water on an allocation basis for both public and private uses. Certain wells have pump capacities less than 70 gpm, while the Lakehurst Naval Air Station and the Glidden-Durkee Company in Lakehurst divert groundwater in excess of 100,000 gpm without a permit because of 'grandfather rights'. No groundwater contamination is in the area that threatens water quality. (Garrison-Omniplan)

TUG HILL AQUIFER: PLANNING AND EDUCATIONAL NEEDS,
Cornell Univ., Ithaca, NY. Center for Environmental Research.
H. B. Hughes, and K. S. Porter.
Report, 1980. 40 p, 7 Fig, 1 Tab, 2 Ref, 2 Append.

Descriptors: *Aquifer management, *Aquifer characteristics, *Stream discharge, *Projections, *Pollutants, *Education, Saturation zone, Public participation, Long-term planning, Social participation, Regional development, Chemical wastes Citizen participation.

To identify and evaluate management strategies for the use and protection of the Tug Hill Aquifer in upstate New York, specific aims were developed including technical methods for planning and management, and the preparation and dissemination of readily usable information for local residents. The proposed steps to carry out these aims include an update of land use data, construction of a water budget for the area, drilling test wells, collecting samples for baseline quality, analyzing present and future risks with contaminant budgets, measuring gain loss streamflow, analyzing water for specific contaminants of concern, producing community education products, producing maps and reports about the saturated zone and interactions with streams, and producing a manual for evaluating situations of opportunity or potential threat. These steps could be done in four phases: (1) determining catchment of wells and maximum time of contaminant travel; (2) building a mathematical model for water and contaminants near the surface; (3) diagnosing existing problems, if any; and (4) examining the implications of present and future conditions. Because of the need to allow for any uncertainties involved in doing contaminant budgets for hazardous chemicals in consumer products, a planner might suggest modification to a plan for a major development in a well catchment of a water supply well. The educational aspect of the project can be handled using public meetings, field trips, a guidebook, and microcomputers. (Garrison-Omniplan)

REACTIONS OF HEAVY METALS AND OTHER MINERAL WATER QUALITY CONSTITUENTS WITH SOIL MATERIALS IN RAPID INFILTRATION GROUNDWATER RECHARGE SYSTEMS USING RECLAIMED WASTEWATERS,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
S. V. Mattigod, and P. F. Pratt.
Available from the National Technical Information Service, Springfield, VA 22161, as PB84 154251, Price codes: A03 for paper copy, A01 for microfiche. California Water Resources Center Completion Report, Univ. of California, Davis, November, 1983. 12 p, 7 Tab, 8 Ref, 1 Append. Project No. OWRT A-079-CAL (3).

Descriptors: *Reclaimed water, *Wastewater, *Wastewater renovation, *Groundwater recharge, *Reclaimed water, *Heavy metals, Water quality, Infiltration, Percolation, Soil chemistry, Soil properties, Superstition sand, San Emigdio soil.

Solutions containing Ca, Mg, K, Na, Pb, Ni, Cd, Cr, Cu, Zn, NH4, SO4, Cl, HCO3, PO4 at concentrations that are typically encountered in wastewaters were allowed to percolate through soil columns 15 cms in diameter and 200 cm deep in two soils; San Emigdio and Superstition sands with known physical and chemical properties were used in these experiments. The analysis of the percolating waters indicated that the trace metal concentrations were attenuated to the extent of non-detectability by atomic absorption spectrometry. The San Emigdio soil showed greater attenuation of PO4 and NH4 in comparison with Superstition sand. Speciation calculations by using GEOCHEM indicated that the major fractions of the trace metals were in cationic form and therefore would be adsorbed by the soil exchange complex. Simulations that include the presence of dissolved organics indicated that a major fraction of Cu, Ni, and Zn were complexed by the organic ligands. The speciation of Cd and Pb on the other hand were mainly influenced by the inorganic ligands. (Snyder-California)

NUMERICAL MODEL TO EVALUATE PROPOSED GROUND-WATER ALLOCATIONS IN SOUTHWEST KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
D. G. Jorgensen, H. F. Grubb, C. H. Baker, Jr., G. E. Hilmes, and E. D. Jenkins.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $5.75 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4095, 1982. 46 p, 14 Fig, 1 Tab, 8 Ref.

Descriptors: *Groundwater management, Computer model, *Water rights, *Kansas, Water allocation, Interactive programs.

A computer model was developed to assist the Southwest Kansas Groundwater Management District No. 3 in the evaluation of applications to appropriate ground water. The model calculated the drawdown due from a proposed well at all existing wells in the section of the proposed well and at all wells in the adjacent eight sections. The depletion expected in the 9-square-mile area due to all existing wells and the proposed well is computed and compared with allowable limits defined by the management district. An optional program permits the evaluation of allowable depletion for one or more townships. All options are designed to run interactively, thus allowing for immediate evaluation of proposed ground-water withdrawals. (USGS)

4C. Effects On Water Of Man's Non-Water Activities

POTENTIAL EFFECTS OF SURFACE COAL MINING ON THE HYDROLOGY OF THE SNIDER CREEK AREA, ROSEBUD AND ASHLAND COAL FIELDS, SOUTHEASTERN MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
M. R. Cannon.
Available from the Ofss, USGS, Box 25425, Fed. Ctr. Denver, CO 80225; Price: $4.00 paper copy, $3.50 microfiche. USGS Water-Resources Investigations Report 82-4051, February, 1983. 28 p, 3 Tab, 23 Ref.

Descriptors: *Coal mines, Hydrology, Groundwater, Wells, Data collection, Rosebud coal field, *Montana, *Mining impacts, Snider Creek, Ashland coal field.

The Snider Creek area of the Rosebud and Ashland coal fields contains strippable reserves of Federal coal that have been identified for potential lease sale. A hydrologic study has been conducted in the potential lease area to describe the existing hydrologic systems and to assess potential impacts of surface coal mining on local water resources. Hydrogeologic data collected from stock wells, observation wells, and drill holes indicate that shallow aquifers exist within the Tullock, Lebo Shale, and tongue River Members of the Fort Union Formation (Paleocene age) and within valley alluvium (Pleistocene and Holocene age). Most of the wells in the area are completed in the basal part of the Tongue River Member or in the upper part of the Lebo Shale Member and are used for watering of livestock. Small stock reservoirs are the primary source of surface water; Snider Creek and all other streams that originate in the area are ephemeral. The Terrett coal bed, the primary coal bed of the area, is located above the water table. Mining of the Terrett coal bed would destroy one stock well and several small reservoirs. Four other wells near the coal outcrop might be destroyed by mining. Alternative ground-water supplies are available to replace those lost by mining. Degradation of the quality of ground water, caused by the leaching of soluble salts from mine spoils, is not anticipated. (USGS)

MAN-INDUCED CHANNEL ADJUSTMENT IN TENNESSEE STREAMS,
Geological Survey, Nashville, TN. Water Resources Div.
C. H. Robbins, and A. Simon.
USGS Water-Resources Investigations Report 82-4098, 1983. 129 p, 71 Fig, 5 Tab, 38 Ref.

Descriptors: *Aggradation, *Alluvial rivers, *Degradation, *Specific gage, *Tennessee, Erosion, Stages, Flood plains, Bridges, Hydraulic design, Shear stress, Mathematical equations, Streams, Streambeds, Fluvial morphology, Slope adjustment, Knickpoint migration, Bed level lowering, *Channelization.

Channel modifications in Tennessee, particularly in the western part, have led to large-scale instabil ities in the channelized rivers and may have contributed to several bridge failures. These modifications, together with land-use practices, led to downcutting, headward erosion, downstream aggradation, accelerated scour, and bank instabilities. Changes in gradient by channel straightening caused more severe channel response than did dredging or clearing. Large-scale changes continue to occur in all the channelized rivers: the Obion River, its forks, and the South Fork Forked Deer River. However, the non-channelized Hatchie River in west Tennessee not only withstood the natural stresses imposed by the wet years of 1973 to 1975 but continues to exhibit characteristics of stability. Water-surface slope, the primary dependent variable, proved to be a sensitive and descriptive parameter useful in determining channel adjustment. Adjustments to man-induced increases in channel-slope are described by inverse exponential functions of the basic form $S=ae(-b(t))$; where 'S' is some function describing channel-slope, 't' is the number of years since completion of channel work, and 'a' and 'b' are coefficients. Response times for the attainment of 'equilibrium' channel slopes are a function of the magnitude and extent of the imposed modifications. The adjusted profile gradients attained by the streams following channelization are similar to the predisturbed profile gradients, where no alteration to channel length was made. Where the channels were straightened by constructing cut-offs, thus shortening channel length, then slope adjustments (reduction) proceed past the predisturbed profile gradients, to new profiles with lower gradients. (USGS)

EFFECTS OF URBAN DEVELOPMENT ON THE AQUIFERS OF THE MEMPHIS AREA, TENNESSEE,
Geological Survey, Nashville, TN. Water Resources Div.
D. D. Graham.
USGS Water-Resources Investigations Report 82-4024, 1982. 20 p, 6 Fig, 3 Tab, 21 Ref.

Descriptors: *Tennessee, *Water supply, *Groundwater, *Aquifers, Land subsidence, Groundwater pollution, Landfills, Waste disposal, Groundwater movement, Potentiometric level, Memphis area, Withdrawal.

Ground-water withdrawals from aquifers in the Memphis area average about 190 Mgal/d. Potential problems associated with increases in pumpage and urban development are lowered water levels, contamination of the aquifers, and land subsidence. Long-term water-level declines in the Memphis Sand, the principal artesian aquifer of the area, range from less than 0.1 ft per year near the outcrop area to about 1.8 ft per year near the center of pumping. A 1980 map of the potentiometric map surface shows that small cones of depression around major pumping centers are superimposed on a regional cone. Except for increased pumping lift, few problems are expected from water level declines in the Memphis Sand. At present, there is very little pumpage from other aquifers in the area--the alluvium, the fluvial deposits and the Fort Pillow Sand--and no long-term water level declines are expected unless pumpage is increased significantly. Low concentrations of leachates from waste-disposal sites in the area have been detected in the water table aquifers near these sites, but no indication of contamination of the underlying artesian aquifers has yet been found. Seasonal land-surface elevation changes of less than 0.03 ft have been recorded by an extensometer near the center of the major cone of depression of the Memphis Sand. These changes correlate with seasonal changes in artesian pressure in the Memphis Sand. Over the period of record no significant net change in land-surface elevation has been recorded. (USGS)

POTENTIAL EFFECTS OF SURFACE COAL MINING ON THE HYDROLOGY OF THE GREENLEAF-MILLER AREA, ASHLAND, COAL FIELD, SOUTHEASTERN MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
G. W. Levings.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $4.50 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4101, Feb. 1983. 31 p, 5 Fig, 5 Tab, 25 Ref.

Descriptors: Hydrology, Strip mines, *Water supply, *Groundwater, Powder River Basin, Ashland coal field, *Montana.

The Greenleaf-Miller area of the Ashland coal field contains reserves of Federal coal that have been identified for potential lease sale. A hydrologic study was conducted in the potential lease area in 1981 to describe the existing hydrologic system and to assess potential impacts of surface coal mining on local water resources. The hydrologic data collected from wells, test holes, and springs were used to identify aquifers in the alluvium (Pleistocene and Holocene age) and the Tongue River member of the Fort Union Formation (Paleocene age). Coal, clinker, and sandstone beds comprise the aquifers in the Tongue River Member. Most streams are ephemeral and flow only as a result of precipitation. The only perennial surface-water flow in the study area is along short reaches downstream from springs. A mine plan for the area is not available; thus, the location of mine cuts, direction and rate of the mine expansion, and duration of mining are unknown. The mining of the Sawyer and Knoblock coal beds in the Tonge River Member would effect ground-water flow in the area. Declines in the potentiometric surface would be caused by dewatering where the mine pits intersect the water table. Wells and springs would be removed in the mine area; however, deeper aquifers are available as replacement sources of water. The chemical quality of the ground water would change after moving through the spoils. The change would be an increase in the concentration of dissolved solids. (USGS)

EFFECTS OF AGRICULTURAL DRAINAGE ON UPLAND STREAMFLOW: CASE STUDIES IN MID-WALES,
Institute of Hydrology, Wallingford (England).
M. D. Newson, and M. Robinson.
Journal of Environmental Management, Vol. 17, No. 4, p 333-348, December, 1983. 7 Fig, 3 Tab, 18 Ref.

Descriptors: *Drainage, *Streamflow, *Land management, *Wales, Runoff, Flood control, Floods, Watercourses, Agricultural runoff, Agricultural hydrology.

Two small sites in mid-Wales were instrumented to investigate claims that the drainage of upland areas for agriculture can lead to an increased flood risk for areas downstream. Measurements at both sites indicated that the effect of the artificial drainage was to reduce the peak rates of outflow into the stream network. This reduction was achieved by a general lowering of the soil water table, providing both an increase in the available moisture storage at times of rainfall and encouraging the movement of water in deeper, less permeable, horizons of the soil. The incidence of waterlogging of surface layers was approximately cut in half, preventing poaching (structural damage of the soil through compaction by stock). While it seems that drainage of farmland would tend to moderate the flood risk downstream, caution must be used in extrapolating these results to specific situations. For example, delaying runoff from areas whose peak flows normally occurred before the catchment peak would tend to build up the overall peak discharge. Farm drainage schemes often require prior improvement of the main watercourses to provide sufficient freeboard for the drain outfalls to discharge freely. Such channel works tend to increase flow velocities and peak discharges and so will tend to counter the effect of slower runoff into the channel

network. This factor may be expected to become increasingly important as larger catchments are considered. (Baker-IVI)

EFFECTS OF CLEARCUTTING AND SITE PREPARATION ON STORMFLOW VOLUMES OF STREAMS IN PINUS ELLIOTTII FLATWOODS FORESTS,
Southeastern Forest Experiment Station, Gainesville, FL.
B. F. Swindel, C. J. Lassiter, and H. Riekerk.
Forest Ecology and Management, Vol. 5, No. 4, p 245-253, April, 1983. 3 Fig, 2 Tab, 9 Ref.

Descriptors: *Storm runoff, *Forest management, *Clearcutting, *Pines, *Florida, Cutting management, Logging, Streamflow, Flood peak, Runoff, Windrowing.

Operational-sized watersheds in pine flatwoods of the Lower Coastal Plain in north Florida were isolated and continuously monitored for 3 1/2 years. Recording flumes assessed quantity of runoff water. After 1 year of calibration monitoring, two of the three watersheds were harvested, site-prepared, and planted under distinct harvest and regeneration practices. Minimum practices, imposed on one watershed, consisted of manual shortwood harvest of pinelands, roller drum chopping of harvest residues and residual understory, bedding, and planting. Maximum practices, imposed on another, consisted of tree-length logging of pinelands with heavy equipment, extraction of lightwood stumps, burning and windrowing of logging residue and residual understory, harrowing, bedding, and planting. Both silvicultural systems increased stormflow volumes; but the maximum practices increased stormflow volumes more. Stormflow volumes apparently increased immediately following tree harvests. The increase persisted through site preparation, planting, and subsequently for 1 1/2 years without further detectable change. Based on this and two previous studies on the hydrologic response of flatwoods forests to silviculture, some conclusions were drawn. Peakflow rate is considered to be a sensitive parameter that may be detectably altered by silviculture, including clearcutting. Windrowing appears to be the most influential practice in increasing peakflow rates. Total surface water yield response is quite distinct depending on the silvicultural system employed. Practices that denude and level the soil surface and stream banks may produce a persistent increase in water yield. (Moore-IVI)

PRESCRIBED BURNING OF PINUS OOCARPA IN HONDURAS; I. EFFECTS ON SURFACE RUNOFF AND SEDIMENT LOSS,
Escuela Nacional de Ciencias Forestals, Comayagua (Honduras).
J. Hudson, M. Kellman, K. Sanmugadas, and C. Alvarado.
Forest Ecology and Management, Vol. 5, No. 4, p 269-281, April, 1983. 3 Fig, 2 Tab, 14 Ref.

Descriptors: *Prescribed burning, *Runoff, *Soil erosion, *Pines, *Honduras, Slope, Vegetation, Grasses, Forbs.

The effects of low-intensity prescribed burning on surface runoff and sediment loss were studied in a stand of oocarpa pine (Pine oocarpa Schiefe) in central Honduras. The effects of burning in two seasons were compared on small paired plots on 10 degree, 25 degree and 40 degree slopes. Over a period of almost 2 years, mean percent runoff was 1.73% on the control plots and 5.03% on the burned plots. Mean sediment loss during the same period was 80 kg/ha on the control plots and 1732 kg/ha on the burned plots. The relationship between slope and surface runoff and sediment loss was negative; the effect of slope being masked by variation of other site factors. Recovery from burning was rapid and is attributed to the rapid rate of recovery of the ground vegetation of grasses and forbs which are adapted to frequent burning. Surface runoff and sediment loss on control plots were very low and the increases caused by burning are considered an acceptable alternative to the exposure of the overstory and site to the high risk of wildfires in accumulated fuels. Greater runoff and sediment loss were recorded on the plots buring in February than on those burned in June. As the period November to mid-February offers the greatest number of days with weather conditions suitable for low-intensity prescribed burning, it is concluded that burning for hazard reduction should be conducted as early as possible in this period, in November and December, to permit greater recovery of the ground vegetation before the heavy rains of May and early June. REDUCED-RANK PREDICTION MODEL OF STREAM-CHANNEL SIZE RESPONSE TO TRADITIONAL AGRICULTURAL LAND-USE PRACTICES IN SOUTHWESTERN NIGERIA,
Benin Univ., Benin City (Nigeria). Dept. of Geography.
F. O. Odemerho.
Journal of Hydrology, Vol. 70, No. 1-4, p 85-100, 1984. 9 Tab, 28 Ref.

Descriptors: *Land use, *Channel morphology, *Channel size, *Nigeria, Channel erosion, Fallowing, Farming, Overland flow, Environmental effects.

Stream-channel morphologic responses are found to be related to different parameters measuring traditional agricultural land-use patterns and practices in 50 small headwater basins in southwest Nigeria. The problem of intercorrelations among these parameters made it initially difficult to establish their precise channel enlargement effects and to calibrate an impact prediction model. Through factor analysis of the 22 land-use and morphometric parameters, six factors identified as measures of traditional land-use practice, farm size, planting activities, shortened fallow, relief and overland flow, were found to account for 86% of the variance in the data. The factor-defining variables are length of cropping period, areas in short fallow, farm-plot size, length of farm preparation relief ratio and overland flow. In a multiple regression analysis, only the first three variables were found to be statistically significant in explaining stream-channel morphologic responses. Thus, areas in short fallows, average farm size and length of cropping period adequately described those aspects of the traditional farming practices that effect basin hydrologic and channel responses. Since these variables were orthogonally derived, they formed the basis for the evaluation of the channel impact status of traditional land-use activities. The duplication of information and effects in the original 22-variable full-rank model were removed while utilizing the three-factor reduced model. (Author's abstract)

4D. Watershed Protection

STRAW RESIDUE TO CONTROL FURROW EROSION ON SLOPING, IRRIGATED CROPLAND,
Agricultural Research Service, Kimberly, ID. Snake River Conservation Research Center.
R. D. Berg.
Journal of Soil and Water Conservation, Vol. 39, No. 1, p 58-60, January-February, 1984. 1 Fig, 4 Tab, 4 Ref.

Descriptors: *Erosion control, *Farm management, *Straw, *Idaho, *Irrigation, Crop yield, Sedimentation, Silt, Soil conservation.

Many fields in southern Idaho have a relatively flat slope at the upper end and a steep slope toward the middle or lower end of the field. During irrigation, flow velocity increases on the steeper sloping sections of furrows, and soil erosion increases greatly. Small amounts of straw placed uniformly in steeply sloping portions of irrigation furrows reduced soil erosion and sedimentation on three fields with an erodible silt loam soil. Erosion was eliminated during the first irrigation on two fields in the straw-treated plots and markedly reduced during subsequent irrigations on these plots and on the third field. The reduction ranged from 30 to 100% in straw-treated furrows compared to furrows without straw. Straw treatment also increased infiltration and lateral water movement significantly, and crop yields rose 7 to 16%. Placing straw in the furrows below the critical-slope areas resulted in the trapping of too much sediment. Furrows filled with sediment, resulting in inadequate irrigation of downslope portions of the field. (Baker-IVI)

WATERSHED RESPONSES TO CONSERVATION MEASURES,
Central Soil and Water Conservation Research and Training Inst., Dehra Dun (India).
G. Sastry, and V. V. D. Narayana.
Journal of Irrigation and Drainage Engineering, Vol. 110, No. 1, p 14-21, March, 1984. 3 Fig, 2 Tab, 6 Ref.

Descriptors: *Water conservation, *Watershed management, *Doon Valley, *India, Forest watersheds, Agricultural watersheds, Runoff, Soil conservation, Check dams, Soil loss, Land use, Grazing.

In Doon Valley, India, when a natural forest watershed open to grazing is deforested and cultivated, volume and peak rates of runoff were higher by 15% and 72%, respectively. When the agricultural watershed is treated with soil and water conservation measures (construction of small field levees or bunds), the peak rate and volume of runoff are reduced by 86% and 62%, respectively, of the corresponding values when it was a natural forest watershed and the corresponding reduction in soil loss was 94%. When another comparable natural forest watershed is provided with brushwood check dams at appropriate locations, although no appreciable reduction in peak rate of runoff was observed, soil loss was reduced by 54%. 5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

WATER POLLUTION: A VIEW FROM ECOLOGY,
McGill Univ., Montreal (Quebec). Inst. of Oceanography.
G. Sabatini, and B. M. Marcotte.
Marine Pollution Bulletin, Vol. 14, No. 7, p 254-256, 1983. 1 Tab, 15 Ref.

Descriptors: *Bioassay, *Water pollution effects, Industrial wastes, Environmental effects, Pollutant identification, Trout, Diatoms, Marine bacteria.

The results of various methods typically used by governments to assess the environmental impact of potential pollutants do not give comparable results. It is argued that the cause is not the assessment techniques themselves, but rather the paradigm of ecology from which they spring. Three bioassays are examined: LC-50, EC-50, and CI-50. The potentially toxic pollutant tested with the three bioassays was a heavy metal effluent from a plating industry containing 1.5 ppm Cr and 26.3 ppm Ni. Bioassay species used included the trout Salmo gairdnerii, the marine diatom Thalassiosira pseudonana and the marine bacterium Photobacterium phosphoreum. Three entirely different results were obtained with the three different techniques used. (Baker-IVI)

ENUMERATION OF THE BACTERIAL CONTAMINATION OF BIVALVES IN MONITORING THE MARINE BACTERIAL POLLUTION,
Brest Univ., Quimper (France). Inst. Univ. de Technologie.
A. Plusquellec, M. Beucher, and Y. Legal.
Marine Pollution Bulletin, Vol. 14, No. 7, p 260-263, 1983. 3 Fig, 3 Tab, 13 Ref.

Descriptors: *Enumeration, *Bacteria, *Contamination, *Bivalves, *Marine pollution, Shellfish, Coliforms, Streptococci, Water pollution, Detection limits, Bacterial analysis, Bioindicators, Fate of pollutants.

Marine organisms such as shellfish are capable of filtering large amounts of sea water and of retaining pathogenic bacteria. This property constitutes a way for evaluating the level of bacteria contamination in sea water. The enumeration of bacterial contamination was based on current fecal indicators. The sensitivity of mussels to concentrate bacteria is important and can be useful for detecting low levels of contamination which would otherwise be poorly evaluated by a direct analysis of water. The concentration factor appears to be more important for streptococci than for coliforms. This result could be the consequence of a differential absorption or a selective trapping of the two kinds of bacteria by the bivalves according to the dimensions of the microorganisms. The comparison between the level of bacteria in mussels and in the surrounding water shows that the contamination of mussels partially reflects that of the water at the same time. Different results would perhaps have been found if the analysis had been based on shellfish meat after the intervalvar water had been withdrawn. Despite some limitations, the use of shellfish as concentrating material appears to improve the bacterial enumeration results both in accuracy and consistency. (Murphy-IVI)

PREDICTING THE BIOACCUMULATION OF ORGANIC COMPOUNDS IN MARINE ORGANISMS USING OCTANOL/WATER PARTITION COEFFICIENTS,
Southern California Coastal Water Research Project Authority, Long Beach.
R. W. Gossett, D. A. Brown, and D. R. Young.
Marine Pollution Bulletin, Vol. 14, No. 10, p 387-392, 1983. 3 Tab, 22 Ref. NOAA grant NA80RAD00040.

Descriptors: *Prediction, *Bioaccumulation, *Organic compounds, *Octanol/water partition coefficients, Sediments, Aquatic fauna, Wastewater disposal, Wastewater management, Wastewater composition.

With the establishment of EPA's Priority Pollutant list, a growing number of wastewaters are now being analyzed for approximately 120 organic compounds. With the increasing number of organic compounds being discharged and the relatively high cost of analysis, it seems prudent to devise a means of assigning priorities as to which of these compounds should be routinely mentioned. One such approach is the utilization of the organic solubility of a compound as a predictive tool for its bioaccumulation by exposed organisms (n-octanol/water partition coefficient). Sediments and animals collected from near the discharge zone of the Los Angeles County wastewater treatment plant were analyzed for 27 selected organic compounds that had been identified in the effluent. The sediment and tissue concentrations of these organic compounds were positively correlated with each other and with the n-octanol/water partition coefficient but these were negatively correlated with the effluent concentration. The n-octanol/water partition coefficients should be used to predict which organics have the potential to bioaccumulate and therefore cause biological effects. (Murphy-IVI)

DETERMINATION OF DISSOLVED ALUMINUM IN WATER SAMPLES,
Geological Survey, Reston, VA. Water Resources Div.
A. A. Afifi.
USGS Water-Resources Investigations Report 82-4018, 1983. 13 p, 5 Fig, 2 Tab.

Descriptors: Chelation, Spectrophotometric analysis, Dissolved aluminum, Moneric aluminum, Adsorption, *Pollutant identification, Methyl isobutyl ketone extract, Standard addition technique, *Aluminum, *Water analysis.

A technique has been modified for determination of a wide range of concentrations of dissolved aluminum (Al) in water and has been tested. In this technique, aluminum is complexed with 8-hydroxyquinoline at pH 8.3 to minimize interferences, then extracted with methyl isobutyl ketone (MIBK). The extract is analyzed colorimetrically at 395 nm. This technique is used to analyze two forms of monomeric Al, nonlabile (organic complexes) and labile (free, Al, Al sulfate, fluoride and hydroxide complexes). A detection limit 2 ug/L is possible with 25-ml samples and 10-ml extracts. The detection limit can be decreased by increasing the volume of the sample and (or) decreasing the volume of the methyl isobutyl ketone extract. The analytical uncertainty of this method is approximately + or - 5 percent. The standard addition technique provides a recovery test for this technique and ensures precision in samples of low Al concentrations. The average percentage recovery of the added Al plus the amount originally present was 99 percent. Data obtained from analyses of filtered standard solutions indicated that Al is adsorbed on various types of filters. However, the relationship between Al concentrations and adsorption remains linear. A test on standard solutions also indicated that Al is not adsorbed on nitric acid-washed polyethylene and polypropylene bottle wells. (USGS)

USE OF A MIXED ALGAL CULTURE TO CHARACTERIZE INDUSTRIAL WASTEWATERS,
Uppsala Univ. (Sweden). Inst. of Physiological Botany.
A. Claesson.
Ecotoxicology and Environmental Safety, Vol. 8, No. 1, p 80-96, February, 1984. 9 Fig, 4 Tab, 12 Ref.

Descriptors: *Algae, *Industrial wastewater, Polyvinylchloride, Textile mill wastes, Chemical wastes, Mine wastes, Pulp wastes, Oil wastes, Algal growth, Bioindicator, Water pollution effects.

There is a great need for the capability to predict the effects of complex wastewater effluents from industrial processes on the natural environment. To be able to increase the value of the predictions, specifically for the recipient, it is necessary to study the influence of an effluent on the living organisms. A mixture of five freshwater algae was cultivated with additions of wastewater samples from chemical, mining, polyvinylchloride, textile, paper mill, and oil refinery industries. Two water samples from chemical industries and one from an oil refinery stimulated the algal growth in a nutrient-poor medium, while growth in other samples, including a nutrient-rich medium, was inhibited in several different ways. For eight of the water samples a delayed growth of 2-4 days was noted. Decreased growth rate and lowered maximal biomass occurred in seven of the samples. The photosynthetic capacity of the algal cells was measured by using in vivo fluorescence of chlorophyll a. These quick measurements mostly agreed with those of the growth rates. When the species composition of the mixed algal culture was investigated, large differences in sensitivities between the different species were found. Stimulation or inhibition were observed in the same sample for different species but also for the same species at different concentrations. To use a mixed algal culture is one attempt to increase the value of prognosis for the fate of substances, products, or industrial wastewaters when discharged into recipients. By exposing algae to constant concentrations of a test sample (flow-through experiments), and by keeping the environmental conditions as equal as possible to the actual effluent situation, more accurate predictions for the recipient situation should be possible. (Murphy-IVI)

RAPID-CELL CULTURE ASSAY OF WATER QUALITY,
Oklahoma State Univ., Stillwater. School of Biological Sciences.
S. R. VanDoren, M. S. Hall, L. B. Frazier, and F. R. Leach.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 2, p 220-226, February, 1984. 1 Fig, 1 Tab, 7 Ref.

Descriptors: *Cultures, *Water quality, *Bioassay, HeLa cells, Monitoring, Toxicity, Thymidine, Pollutants.

A cell culture screen was developed to determine water quality of environmental samples. The assay uses HeLa cells growing on microcarrier beads and a 4 hr thymidine incorporation as a screen for water toxicity. Advantages of the system are: the use of a small volume of water in the test; the ability to do the test and have the final result within a 24 hr period; the use of a large number of cells which eliminates the complications produced by using a few organisms in a bioassay; and the capability of using other biosysnthetic processes to assess toxicity. The use of the assay is demonstrated with two types of environmental samples, one a typical oil refinery effluent and the other a sample of water from the Tar Creek area of Oklahoma which serves as the principal drainage system of the Picher field, one of the most productive lead-zinc mining districts in the United States. USE OF FISH GILL AND LIVER TISSUE TO MONITOR ZINC POLLUTION,
Washington State Univ., Pullman. Dept. of Civil and Environmental Engineering.
J. G. Saltes, and G. C. Bailey.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 2, p 233-237, February, 1984. 1 Fig, 1 Tab, 21 Ref.

Descriptors: *Zinc, *Trout, *Water quality, *Monitoring, Spokane River, Washington, Biological magnification, Fish.

Zinc bioconcentration in 13 rainbow trout and 5 brook trout was determined to understand whether zinc concentrations in gill and liver tissue of the wild salmonids had decreased with the decline in ambient concentrations. The mean and range of zinc concentration in gill and liver tissues of the 1980-81 fish was 1000 (382-1634) and 395 (155-749) micrograms/g, respectively. The mean bioconcentration factors were 9708X for gill and 3835X for liver tissue. It was expected that the zinc concentration of liver tissue of Spokane River fish would reflect the lower ambient concentrations. The fact that this did not occur suggests that there are other unknown factors which account for this discrepancy in tissue concentrations of zinc and zinc exposure for the Spokane River fish. The use of fish tissue as an indicator of metal concentration in an aquatic system may not be appropriate for a metal such as zinc which is homeostatically controlled. Investigators are urged to refrain from using fish as biomonitors of metal pollution until fish response to metal stress can be properly interpreted. (Baker-IVI)

IRON AND HYDROGEN SULFIDE INTERFERENCE IN THE ANALYSIS OF SOLUBLE

REACTIVE PHOSPHORUS IN ANOXIC WATERS,
McGill Univ., Montreal (Quebec). Dept. of Biology.
G. Nurnberg.
Water Research, Vol. 18, No. 3, p 369-377, 1984. 9 Fig, 4 Tab, 40 Ref.

Descriptors: *Water analysis, *Phosphorus, Hydrogen sulfide, Water quality control, Hypolimnion, Chemical analysis, Anoxic water, Iron, Calcium.

Anoxic water from eight lakes containing various amounts of ferrous iron, hydrogen sulfide, calcium and total phosphorus was analyzed for soluble reactive phosphorus (SRP). Hydrogen sulfide concentrations higher than 1 mg/l and ferrous iron concentration above 0.20 mg/l produced interferences in the SRP analysis on many occasions. Interfering concentrations of these materials are present in anoxic water from a large number of lakes, groundwater springs and ocean basins. Ferrous iron is not problematic to the analysis if the sample is kept anoxic before and during filtration. Vigorous aeration is obligatory if hydrogen sulfide is present. For water from the anoxic hypolimnia of the eight lakes a modified analysis of total (unfiltered) reactive phosphorus (TRP) yields on average only 2% lower phosphorus concentrations than SRP analysis. TRP hence can replace the complicated SRP in anoxic water analysis. (Baker-IVI)

GROWTH RESPONSE IN FISH CHRONIC AND EARLY LIFE STAGE TOXICITY TESTS: A CRITICAL REVIEW,
Procter and Gamble Co., Cincinnati, OH. Environmental Safety Dept.
D. M. Woltering.
Aquatic Toxicology, Vol. 5, No. 1, p 1-21, February, 1984. 1 Fig, 4 Tab, 120 Ref.

Descriptors: *Toxicity, *Testing procedures, *Water pollution effects, *Fish, Metals, Pesticides, Organic compounds, Detergents, Inorganic compounds, Effluents, Growth stages.

The utility of the standard fish chronic toxicity endpoints to chemical hazards evaluations was examined through analysis of toxicity data from 25 years of fish life cycle chronic, partial chronic and early life stage tests. Particular emphasis was placed on the growth response. The 173 tests evaluated included exposure to metals, pesticides, unclassified organics, inorganic compounds, detergents and complex effluents. Survival of fry was significantly reduced in 57% of all tests at the lowest effect concentration. Growth of fry was reduced in 36% and egg hatching in 19% of tests. Fry survival and growth were very often correlated as equally sensitive, but fry growth was the single most sensitive response in only 14% of the tests. As presently used, the growth response could be deleted from routine applications of the fish early life stage test. The net result would be a significant reduction in the duration and cost of screening tests with no appreciable impact on estimating the maximum acceptable toxicant concentration (MATC) for chemical hazard assessments. Whether or not to include growth (or reproduction) as a routine endpoint in fish chronic toxicity tests is ultimately a question of what additional sensitivity or information is gained or could be with some modification, and how the time and money should be spent to screen new and expanded-use chemicals and effluents. The available data base suggests that the additional time and expense of the standard growth response in fish early life stage tests are unwarranted for routine chemical hazard assessments. (Baker-IVI)

BEHAVIOURAL BIOASSAY FOR IMPAIRED SEA-WATER QUALITY USING THE PLANTIGRADES OF THE COMMON MUSSEL MYTILUS EDULUS L.: THE RESPONSE TO COPPER,
Sheffield Univ. (England). Dept. of Zoology.
N. M. H. Sheffrin, N. R. J. Fieller, and E. E. Williams.
Aquatic Toxicology, Vol. 5, No. 1, p 77-91, 1984. 6 Fig, 5 Tab, 37 Ref.

Descriptors: *Bioassay, *Copper, *Mussels, *Behavior, Effects of pollutants, Plantigrades, Mytilus, Seawater.

A bioassay is presented which is based upon the ecologically significant behavioral responses of crawling and byssal attachment of the plantigrades of the common mussel for copper-impaired sea water. Potentiometric stripping analysis has been used to quantify the total and electrochemically labile species of copper. The threshold of sensitivity for the bioresponse lies between 13 ppb total, 8 ppb labile and 25 ppb total, 15 ppb labile copper, for a bioassay of 1 hr duration. There is an example of hormesis for the bioresponse of the number of plantigrades that crawl for levels of copper at and below 13 ppb total, 8 ppb labile metal. The effects of light and gravity as directional cues and the effect of animal size and density in the bioassay have also been considered. The test organism is available for most of the year and is economically and ecologically important. Individuals are of similar age/size and from the same area. The bioassay is easy to learn, cheap to run, short in duration and meets the normal statistical requirements. (Baker-IVI)
W84-03743

AUSTRALIAN FRESHWATER MUSSEL VELESUNIO AMBIGUUS (PHILIPPI) AS A BIOLOGICAL MONITOR FOR ZINC, IRON AND MANGANESE,
Adelaide Univ. (Australia). Dept. of Zoology.
P. J. Millington, and K. F. Walker.
Australian Journal of Marine and Freshwater Research, Vol. 34, No. 6, p 873-892, 1983. 10 Fig, 7 Tab, 38 Ref.

Descriptors: *Pollutant identification, *Bioindicators, *Mussels, Zinc, Iron, Manganese, Heavy metals, Velesunio, Australia, River Murray.

The possible use of the hybrid mussel V. ambiguus as a biological monitor of zinc was explored in the River Murray. A high variation in zinc content was found among individuals and between populations. Part of the variation was systematic, associated with body weight and age. However, a larger part remained statistically unexplained. Further, while V. ambiguus readily accumulated zinc, depuration was slow. At zinc concentrations of 210 mg/l and above, mussels avoided taking up zinc by significantly curtailing siphoning, movement and valve opening. At zinc levels above 20 mg/l, lethal level, most deaths occurred in the post-exposure periods immediately after 96-, 176- and 336-hr toxicity tests. The estimated 336 hr LC50 was 66 mg/l with 95% confidence limits 55 and 77 mg/l. Exposure of caged mussels in the zinc-contaminated Molonglo River, New South Wales suggests that V. ambiguus is not suitable as a species to monitor variations in zinc loads between sites, and does not accurately reflect environmental fluctuations of zinc, iron, or manganese, although it may have potential for materials other than heavy metals. (Baker-IVI)

MOLECULAR PHOTOLUMINESCENCE SPECTROMETRY WITH HYDRIDE GENERATION FOR DETERMINATION OF TRACE AMOUNTS OF ANTIMONY AND ARSENIC,
National Research Inst. for Pollution and Resources, Kawaguchi (Japan).
H. Tao, A. Miyazaki, K. Bansho, and Y. Umezaki.
Analytical Chemistry, Vol. 56, No. 2, p 181-185, February, 1984. 6 Fig, 3 Tab, 20 Ref.

Descriptors: *Pollutant identification, *Antimony, *Arsenic, *Spectrometry, Molecular photoluminescence spectrometry, Hydrides, Heavy metals.

Molecular photoluminescence spectrometry is a very sensitive and selective method for the determination of some hydrides and has been used for the determination of antimony and arsenic. Both elements were generated as hydrides and irradiated with ultraviolet light. The broad continuous emission bands were observed in the ranges about 240-750 nm and 220-720 nm, and the detection limits were 0.6 ng and 9.0 ng for Sb and As, respectively. Some characteristics of the photoluminescence phenomenon were made clear from spectroscopic observations. After the interference study, the method was successfully applied to the determination of antimony in river water and seawater. The advantages of this method include wide dynamic range and good selectivity plus a low and stable background level. (Baker-IVI)
W84-03752

DETERMINATION OF TRACE ANIONS IN WATER BY MULTIDIMENSIONAL ION CHROMATOGRAPHY,
Environmental Research Lab., Athens, GA.
T. B. Hoover, and G. D. Yager.
Analytical Chemistry, Vol. 56, No. 2, p 221-225, February, 1984. 6 Fig, 3 Tab, 18 Ref.

Descriptors: *Pollutant identification, *Water analysis, *Ion chromatography, Selenium, Arsenic, Selenates, Senenites, Arsenates, Chlorides, Nitrates, Sulfates, Drinking water, Water quality control, Chromatography.

Selenate, selenite, and arsenate ions were separated from the major anions chloride, nitrate, and sulfate in drinking water, surface water, and groundwater souces by collecting a selected portion of the ion chromatograph, after suppression, on a concentrator column and reinjecting at the original chromatographic conditions. Statistical detection limits varied from 0.02 to 1.2 micrograms of trace element depending on the minor components to be separated and on the water matrix but independent of initial sample size from 2 to 10 ml. The maximum reliably separated molar ratio was 1300 for sulfate/selenate in well water. Carbonate-bicarbonate eluent compositions were optimized for each trace ion. The technique is not applicable to anions of weak electrolytes that are not retained by the concentrator, e.g., fluoride, cyanide, or arsenite. (Baker-IVI)
W84-03753

DETERMINATION OF LOW LEVELS OF BROMIDE IN FRESH WATER AFTER CHROMATOGRAPHIC ENRICHMENT,
Uppsala Univ. (Sweden). Dept. of Analytical Chemistry.
U. Lundstrom, A. Olin, and F. Nydahl.
Talanta, Vol. 31, No. 1, p 45-48, January, 1984. 5 Tab, 8 Ref.

Descriptors: *Bromide, *Fresh water, *Chromatographic enrichment, Sodium perchlorate, Chloride, Sweden.

A method has been developed for the determination of bromide in fresh water. The analyte is enriched on the anion-exchanger Dowex 1 x 8, which exhibits a considerably greater affinity for bromide than for the major anions in fresh water. Sodium perchlorate is used as eluent and an enrichment factor of about 100 can be achieved. The eluted bromide is oxidized with peroxodisulfate to bromate, which is determined iodometrically by a previously published spectrophotometric method. The enrichment in the presence of the major components of fresh water has been studied. Only bicarbonate has been found to interfere, but this interference can be avoided by acidifying the sample with hydrochloric acid. The recovery from synthetic fresh water with ionic concentrations corresponding to 0.005 equivalent/l and spiked with bromide was 100% at bromide concentrations larger than 50 n M (4 microg/l) and about 90% at 10 nM. The detection limit is 1.5 nM and the limit of determination 5 nM for 1-liter samples. (Author's abstract)
W84-03802

DIATOMS AS INDICATORS OF THE RATE OF LAKE ACIDIFICATION,

Brock Univ., St. Catharines (Ontario). Dept. of Biological Sciences.
M. Dickman, S. Dixit, J. Fortescue, B. Barlow, and J. Terasmae.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 375-386, January, 1984. 7 Fig, 1 Tab, 21 Ref.

Descriptors: *Diatoms, *Bioindicators, *Lake acidification, Hydrogen ion concentration, Sediments, Water pollution effects, Acid rain, History, Lakes, Acid water.

Autecological studies of diatoms as pH indicators have opened the way to estimating a lake's past pH on the basis of its diatom species composition and relative abundance. Estimating the rate of lake acidification from its sediment subfossil diatoms is possible when these subfossils can be identified and accurately enumerated in the surface sediments of 20 to 30 lakes. Once this is done the diatoms down the length of the sediment core of one or more of these lakes can be enumerated and the pH inferred at each depth. This technique holds considerable promise in assessing the temporal impact of acid precipitation for acid-sensitive lakes. When log values were regressed against observed pH for 28 lakes located north of Lake Superior, a significant ($P < 0.01$) correlation ($r = 0.89$) resulted. Down-core diatom stratigraphy for one of these lakes indicated that its pH had dropped from 6.2 to 5.2 over the last 2 yr while a second lake had dropped from a pH of 7.1 to 5.2 over the last 30 yr. The diatom inferred pH technique, when carefully calibratd in the study area in which it is used has proved to be a valuable tool in estimating the rate of lake acidification. (Murphy-IVI)

IDENTIFICATION OF CHLORINATED NITROBENZENE RESIDUES IN MISSISSIPPI RIVER FISH,
Food and Drug Administration, Washington, DC. Div. of Chemical Technology.
M. P. Yurawecz, and B. J. Puma.
Journal Association of Official Analytical Chemists, Vol. 66, No. 6, p 1345-1352, November, 1983. 2 Fig, 3 Tab, 10 Ref.

Descriptors: *Chlorinated nitrobenzene, *Mississippi River, *Fish, Industrial wastes, Bioindicators, Pesticides, Organochlorine, Organophosphorus,.

FDA monitoring programs for pesticide and industrial chemical residues in foods have included analyses of selected food samples, mainly of domestic fresh-water fish, for residues of electron-capturing industrial chemicals. These residues are recovered in the 6% ethyl ethel-petroleum ether eluate of the Florisil cleanup procedure, but are too volatile for electron capture gas chromatography analysis at the operating conditions recommended. Residues of lower chlorinated nitrobenzenes have been found at levels up to about 1 ppm in 8 samples of Mississippi River fish. Electron capture gas chromatography (EC/GC) was used for determination after extraction and cleanup using a procedure based on the AOAC multiresidue method for organochlorine and organophosphorus pesticides in nonfatty foods. The residues found included 2-, 3-, and 4-chloronitrobenzene and 2,3- and 3,4-dichloronitrobenzene, identify was confirmed by GC/mass spectrometry. GC retention times for 15 monochloro-through pentachloro-substituted nitrobenzene congeners were determined with OV-101 and mixed OV-101 + OV-210 columns at 130 degrees C. In studies of the nonfatty food extraction and cleanup procedures of the AOAC method, recoveries of 15 chlorinated nitrobenzenes from spiked fish samples ranged from 68 to 116%. GC of cleaned up fish extract aliquots equivalent to 20 mg sample allowed quantitation of individual congeners at levels of about 0.025 and 0.005 ppm with H-3 and Ni-63 EC detectors, respectively. The contamination of Mississippi River fish with chlorinated nitrobenzenes appears to be localized in a 150 mile section of the river extending from St. Louis, MO, to Cape Girardeau, MO; no chlorinated nitrobenzenes (< 0.005 ppm) were detected in Mississippi River fish caught above or below this region of the river or in fish from the lower Missouri River, which joins the Mississippi River near St. Louis. (Murphy-IVI)

DETERMINATION OF SULPHATE IN NATURAL WATER BY FLOW-INJECTION ANALYSIS,
Okayama Univ., Kurashiki (Japan). Inst. for Agricultural and Biological Sciences.
S. Nakashima, M. Yagi, M. Zenki, M. Doi, and K. Toei.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 1, p 29-31, 1984. 3 Fig, 1 Tab, 4 Ref.

Descriptors: *Sulfate, *Natural waters, *Flow-injection analysis, Cations, Ions, Japan.

Sulfate was determined in natural water samples by flow-injection analysis using dimethylsulfonazo-III as reagent. The interference by Ca was eliminated by a cation-exchanger column inserted directly after the sample injection valve. In order to ensure high sensitivity and reproducibility it was necessary to saturate the carrier solution with barium sulfate and to fill the reaction coil with ethanol-water (1:1) when not in use. Standard deviations were 0.94-1.2% for 6-10 mg/l sulfate. The limit of detection was about 0.2 mg/l. The calibration graph was linear up to 14 mg/l. Mg(2+), NH4(+), Na(+), K(+), Cl(-), NO3(-), PO4(3-), HCO3(-) and SiO3(2-) did not interfere in the normally occurring concentrations. (Author's abstract)

TRIBUTYLTIN DETECTION AT TRACE LEVELS IN WATER AND SEDIMENTS USING GC WITH FLAME-PHOTOMETRIC DETECTION AND GC-MS,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
M. D. Mueller.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 1, p 32-36, 1984. 3 Fig, 2 Tab, 13 Ref.

Descriptors: *Tributyltin, *Trace levels, Sediments, Water analysis, Gas chromatography.

A sensitive and specific method for the determination of low levels of tributyltin (TBT) in water and sediments is presented. The procedure is based on the conversion of tributyltin compounds to tributylmethyltin (TBMeT) and analysis using GC with flame photometric detection (GC-FPD) and GC-MS. Detection limits of less than 1 ppt for water and 0.5 ppb for sediment are achieved. River and lake water and lake sediments analyzed show tributyltin to be present in the low ppt- and ppb-range, respectively. (Author's abstract)
W84-03899

SPECTROPHOTOMETRIC DETERMINATION OF NITRITE PRODUCED BY FLOW-ELECTROLYSIS OF NITRATE,
Fukui Univ. (Japan). Dept. of Chemistry.
R. Nakata.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 2, p 115-117, 1984. 6 Fig, 1 Tab, 12 Ref.
Japanese Ministry of Education, Science and Culture grant 57740288.

Descriptors: *Spectrophotometry, *Nitrite, Electrolysis, Ions, Natural waters, nitrate, Copper, Cadmium.

The electrocatalytic reduction of nitrate to nitrite with a carbon column electrode in the presence of Cu(2+) and Cd(2+) was investigated in a flow system. Electrogenerated nitrite was mixed with color-producing reagents and detected colorimetrically. In acetate and phosphate buffer solutions, the reduction of nitrate to nitrite or further reduction of nitrite was monitored by scanning the electrode potential. In phosphate buffer solutions, the yield of nitrite went up to a maximum in the presence of Cu(2+) and Cd(2+) at above -1.1 V. The electrocatalytic reduction method was applied to the determination of nitrate in river water instead of the conventional Cu-coated Cd column. (Author's abstract)

INDIRECT TRACE DETERMINATION OF NTA IN NATURAL WATERS BY DIFFERENT PULSE ANODIC STRIPPING VOLTAMMETRY,
Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. fuer Angewandte Physikalische Chemie.
A. Voulgaropoulos, P. Valenta, and H. W. Nurnberg.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 3-4, p 367-371, 1984. 2 Fig, 4 Tab, 16 Ref.

Descriptors: *Nitrilotriacetic acid, *Natural waters, Measuring instruments, Voltammetry, Bismuth, Cadmium, Copper, Lead, Zinc, Iron.

Nitrilotriacetic acid (NTA) appears to be the most suitable substitute for sodium tripolyphosphate to prevent the eutrophication of natural waters. Bismuth(III) is added in excess in the water sample to NTA and EDTA to form inert stable complexes at pH 2. The uncomplexed Bi(III) is then deposited into a hanging mercury drop electrode at a potential of -0.15 V vs. SCE and subsequently stripped anodically in the differential pulse mode. The peak current of uncomplexed Bi(III) is recorded. By a second deposition at -0.35 V vs. SCE Bi(III) from Bi(3+) and Bi-NTA is deposited. The concentrations of NTA and EDTA in the sample are determined from the concentration of added Bi(III) and the voltammetrically determined Bi(III) at these two potentials by the standard addition method. Cd, Cu, Pb, and Zn do not interfere. Fe(III) has to be reduced by ascorbic acid or hydroxylamine before the determination. Cu(II) in concentrations larger than 40 microg/l has to be removed by preelectrolysis. In samples with chloride contents above 0.05 M the stripping step has to be performed after medium exchange to a perchloric acid solution of pH 2. For a deposition time of 2 min the determination limit is approximately 0.2 microg/l NTA and 0.1 microg/l EDTA. The relative standard deviation for NTA concentrations at 2 or 10 microg/l lies at 10 or 1.3%, respectively. Good accuracy is established by finding within 2% the levels adjusted when water samples are spiked with a standard solutions of NTA or EDTA. (Murphy-IVI)

FRESHWATER MOLLUSCS AS ACCUMULATION INDICATORS FOR MONITORING HEAVY METAL POLLUTION,
Universitaet des Saarlandes, Saarbruecken (Germany, F.R.). Lehrstuhl fuer Biogeographie.
L. Zadory.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 3-4, p 375-379, 1984. 6 Fig, 2 Tab.

Descriptors: *Mollusks, *Bioindicators, *Heavy metals, Water pollution, Behavior, Synergistic effects, Cadmium, Lead, Zinc, Saar River, Federal Republic of Germany.

For monitoring heavy metal pollution of streams in urban and industrial areas residue analyses were undertaken in different aquatic invertebrates with

special regard to the freshwater mollusks Bithynia tentaculata, Physa acuta, Radix peregra and Dreissena polymorpha to define the heavy metal residues in shell and soft body parts in natural populations. To control the distribution and dynamics of the heavy metals, the accumulation and elimination behavior is determined after experimental contamination tests with cadmium, lead and zinc and their complexes for synergisms on standardized populations under laboratory conditions. Due to a strong accumulation of these organisms they appear to be well suited for monitoring programs. Experimental studies show, that zinc and lead absorbed with the food accumulate in the hemolymph, the food muscle and the protein gland. The different rates of accumulation depend however among others on the different physiological variables as well as on population specific strategies. Furthermore, different mechanisms result in a rivalry among the heavy metals for uptake. (Author's abstract)

NITRATE IN DRINKING WATER OF WINE-GROWING AREAS - AN ION-CHROMATOGRAPHIC STUDY (NITRAT IM TRINKWASSER VON WEINBAUGEBIETEN - EINE IONEN-CHROMATOGRAPHISCHE STUDIE),
Goettingen Univ. (Germany, F.R.). Inst. fuer Anorganische Chemie.
T. Darimont, G. Schulze, and M. Sonneborn.
Fresenius Zeischrift fur Analytische Chemie, Vol. 317, No. 3-4, p 400-406, 1984. 7 Fig, 2 Tab, 51 Ref.

Descriptors: *Nitrate, *Drinking water, Ion chromatography, Farm wastes, Fertilizers, Wine orchards, Water pollution, Oberrhein, Main, Neckar, Federal Republic of Germany.

Wine-growing uses extremely high doses of nitrogenous fertilizer which can influence the quality of drinking water when washed out. To quantify the problem of burdening, drinking water was sampled from taps at 254 sites covering the wine-growing areas of Oberrhein, Main and Neckar. These samples were examined for their content of nitrate by means of ion-chromatography. 13% of the samples exceed the maximal concentration admissible and 42% are above guide levels. For the regions of Wurzburg, Wurttembergisch Unterland and Kaiserstuhl-Tuniberg-Markgraflerland which are particularly loaded with nitrate it can be proved that artificial fertilizers do indeed influence the quality of drinking water. In these cases a dependence of nitrate concentration in drinking water on the local situation of the water catchment places - in view of areas used for wine-production is given. A nitrate register for drinking water was established; it shows that parts of the population, who are particularly concerned, are additionally nitrate-burdened through drinking water by a factor of approximately four in comparison with other foods. A critical examination of purely immission-covering possibilities for the reduction of nitrate burdening leads to the necessity of regulations for limiting the emissions. (Murphy-IVI)

COMPARISON OF CONTINUOUS-FLOW (CFA) AND FLOW-INJECTION (FIA) TECHNIQUES FOR THE PHOTOMETRIC DETERMINATION OF TRACES OF ALUMINIUM IN WATER AND SOIL SAMPLES (VERGLEICH VON CONTINUOUS-FLOW-UND FLOW-INJECTION-ANALYSENTECHNIKEN ZUR PHOTOMETRISCHEN BESTIMMUNG VON ALUMINIUMSPUREN IN WASSERN UND BODEN),
Goettingen Univ. (Germany, F.R.). Inst. fuer Anorganische Chemie.
D. Zoltzer, and G. Schwedt.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 3-4, p 422-426, 1984. 9 Fig, 3 Tab, 2 Ref.

Descriptors: *Continuous flow, *Flow injection, Comparison studies, Aluminum, Water analysis, Soil analysis.

The determination of aluminum is carried out by means of Chromazurol S. Interferences by iron(III) are eliminated by reduction with ascorbic acid. FIA shows more symmetric signals than CFA. By FIA also higher sample frequencies and better reproducibility are obtainable. Only Teflon tubes should be used for the analytical systems because of the adsorption of Al on glass surfaces. Detection limits are about 10 ng/ml of Al. In case of soil solutions and water samples the evaluation has to be performed according to the standard addition method as considerable matrix effects are caused by the organic substances. Only kinetically labile aluminum is determinable. Therefore, comparisons with atomic absorption determinations are presented. Correlations between pH-values of the soil solutions and the part of photometrically determinable aluminum are recognizable. (Author's abstract)

CHLOROPHYLL A TROPHIC STATUS CLASSIFICATION SYSTEM FOR SOUTH AFRICAN IMPOUNDMENTS,
Rhodes Univ., Grahamstown (South Africa). Dept. of Plant Sciences.
R. D. Walmsley.
Journal of Environmental Quality, Vol. 13, No. 1, p 97-104, 1984. 5 Fig, 3 Tab, 30 Ref.

Descriptors: *Chlorophyll a, *Trophic level, *Lake classification, *Reservoirs, Eutrophication, Water management, Algal blooms, Bioindicator, South Africa.

The use of chlorophyll a as an index of trophic status is based on the fact that it is normally the most abundant and important pigment in phytopankton cells; thus, measurements provide a convenient estimate of the phytoplankton biomass in a water body. Chlorophyll a data from 24 South African impoundments were examined with the objective of developing a trophic status classification system. For the combined data set, standard deviation of the mean annual chlorophyll a concentration displayed an almost 1:1 linear relationship to the mean, indicating a wide annual variation in chlorophyll a for most impoundments. There appeared to be no common seasonal pattern to the occurrence of chlorophyll a maxima and minima, leading to the conclusion that trophic status was best described by a statistical parameter based on annual data (notably the mean value). Statistically significant empirical formulae that relate both the maximum value and the frequency of occurrence of specific chlorophyll a ranges to the mean annual value were established, and their potential use in the assessment of trophic status and impoundment management is described. APPLICATION OF SOME BENTHIC INDICES FOR QUALITY EVALUATION OF WATER HIGHLY POLLUTED WITH MUNICIPAL SEWAGE,
Polish Academy of Sciences, Warsaw. Dept. of Ecological Bioenergetics.
M. Kaniewska-Prus, and A. Kidawa.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 3, p 263-269, 1983. 1 Fig, 2 Tab, 21 Ref.

Descriptors: *Water pollution, *Pollutant identification, *Municipal wastes, *Vistula River, *Warsaw, *Poland, Benthic environment, Chemical analysis, Wastewater pollution.

Several commonly used benthic indices describing the degree of water pollution were calculated for four sites of polysaprobic section of the Vistula River below Warsaw, Poland. No significant differences were found in values of these indices between sites. All indices for the four sites showed typical values for highly polluted waters. The lack of change along the 25 km stretch between the first and last site indicate that self purification is not occurring to any significant degree. No significant correlations were found between values of these factors and the chemical properties of the water. The average Chandler's score turned out to be the best for evaluating waters strongly polluted with municipal sewage. It was the least sensitive to water level changes in the river and to seasonal changes in macrobenthos numbers. (Baker-IVI)

ORGANIC CONTAMINANTS IN THE AQUATIC ENVIRONMENT; IV. ANALYTICAL TECHNIQUES,
Imperial Coll. of Science and Technology, London (England). Public Health Engineering Lab.
A. E. McIntyre, and J. N. Lester.
The Science of the Total Environment, Vol. 27, No. 2/3, p 201-230, April, 1983. 196 Ref. Science and Engineering Research Council Grant GR/B/18263.

Descriptors: *Organic compounds, *Pollutant identification, *Analytical methods, Chromatography, Wastewater analysis, Water analysis, Drinking water, Spectrometry, Literature reviews.

Methods currently available for the determination of organic micropollutants in water and wastewater are evaluated in this review. The groups of compounds considered are those which appear in both the EEC Blacklist and Greylist and the U.S. EPA Priority Pollutant list. These include specifically, polynuclear aromatic hydrocarbons, phlychlorinated biphenyls, organochlorine insecticides, phthalic acid esters, chlorophenols, phenols, organophosphorus compounds and other selected compounds of concern. General measures of organic pollution are considered, together with a range of chromatographic and instrumental methods for the analysis of specific groups of pollutants. The most widely used techniques for the measurement of specific compounds are gas liquid chromatography and high performance liquid chromatography. Mass spectrometry and combined gas liquid chromatography/mass spectrometry are the most definitive analytical methods. Solvent extraction procedures are the most suitable for non-volatile organic substances, and gas purging or stripping techniques are favored for the isolation of volatile compounds. Sample purification or clean-up procedures, including column and thin layer chromatography, are of particular importance when waste water samples are to be analyzed, owing to the relatively high concentrations of extraneous materials which have to be removed prior to analysis. (Baker-IVI)

POLLUTION INDICATORS AND POTENTIAL PATHOGENIC MICROORGANISMS IN ESTUARINE RECREATIONAL WATERS,
Nova Scotia Research Foundation, Dartmouth.
W. J. Robertson.
Canadian Journal of Public Health, Vol. 75, No. 1, p 19-24, January/February, 1984. 50 Ref.

Descriptors: *Bioindicators, *Pathogenic bacteria, *Estuaries, *Recreation, Water quality, Pathogens, Fecal coliform, Coliforms, Bacteria, Vibrio parahaemolyticus, Pseudomonas aeruginosa, Salmonella, Candida albicans, Canada.

The quality of marine recreational waters is now assessed using fecal coliforms, the recognized indicator of fecal contamination. It is assumed that the possibility of infections from water-borne pathogens increases as densities of fecal coliform increase. Fecal streptococci are also used as supplementary indicators. However, these indicators possess certain traits which limit their applicability. Within the last few years relatively easy techniques for enumerating the more common water-borne pathogens themselves have been developed, eg. Candida albicans, Pseudomonas aeruginosa, Salmonella and Vibrio spp. Studies are now underway to determine whether their densities correlate well with the presence of fecal indicators, in marine recreational waters. In estuaries the potential pathogen Vibrio parahaemolyticus appears to hold promise as a complementary indicator of the presence of sewage and other potential pathogens. (Author's abstract)

BACTERIAL INDICATORS OF RECREATIONAL WATER QUALITY,
Health Effects Research Lab., Cincinnati, OH.
A. P. Dufour.
Canadian Journal of Public Health, Vol. 75, No. 1, p 49-56, January/February, 1984.

Descriptors: *Bacteria, *Bioindicators, Water quality, Recreation, Escherichia coli, Enterococci, Coliforms, Fecal coliforms, Human pathology, Gastroenteritis, Comparison studies.

The currently recommeded bacterial indicator for measuring the quality of recreational waters in the United States is the fecal coliform group. Correlation analysis was performed on the swimming-associated gastroenteritis rates and the corresponding geometric mean densities of each indicator from multiple beaches and study units. The correlation coefficient was used as the measure of the 'strength' of the relationship between each indicator of water quality and swimming-associated gastroenteritis. The results of the marine and freshwater studies indicate that one bacterial indicator (enterococci) meets most of the ideal characteristics. Most important is the fact that the density of this indicator correlated well with gastrointestinal disease associated with swimming. The regression line of swimming-associated gastrointestinal illness rates on enterococci density indicates that the illness rate approaches zero before the indicator density reaches one. E. coli density showed a strong relationship to health risk in freshwater, but not in seawater whereas fecal coliform density was not related to swimming-associated gastroenteritis in either aquatic environment. Although none of the indicators examined could fulfill all of the suggested characteristics, enterococci were able to meet more of them than E. coli or fecal coliforms. The epidemiologic method does not require establishing pathogen to indicator relationships since only illness incidence is measured. (Murphy-IVI)

SIMULTANEOUS DETERMINATION OF DISSOLVED ORGANIC CARBON AND PHOSPHORUS IN WATERS USING FLAME IONIZATION AND PHOTOMETRIC DETECTORS,
Government Industrial Research Inst., Tosu (Japan).
K. Nakajima.
Water Resources, Vol. 18, No. 5, p 555-559, 1984. 4 Fig, 3 Tab, 16 Ref.

Descriptors: *Simultaneous determination, *Flame ionization, *Photometry, Dissolved organic carbon, Dissolved phosphorus, Organic carbon, Phosphorus, Water quality.

An apparatus with flame ionization and photometric detectors was assembled for the simultaneous determination of dissolved organic carbon (DOC) and phosphorus (DP) in waters. The optimum operating conditions were described. The long-term precision (relative standard deviation) is 5.8% for DOC and 5.2% for DP. The detection limits are 0.09 microg/ml for DOC and 0.03 microg/ml for DP. The responses for various DOC and DP compounds agreed almost with those obtained by combustion-infrared and persulfate digestion-colorimetric methods, respectively. DOC and DP in several water samples were determined by this method and other methods, and the results obtained by those methods were discussed. (Author's abstract)
W84-04022

ATOMIC ABSORPTION SPECTROMETRIC DETERMINATION OF ARSENITE IN WATER SAMPLES BY GRAPHITE FURNACE AFTER EXTRACTION WITH AMMONIUM SEC-BUTYLDITHIOPHOSPHATE,
Texas A and M Univ., College Station. Dept. of Chemistry.
D. Chakraborti, K. J. Irgolic, and F. Adams.
Journal Association of Official Analytical Chemists, Vol. 67, No. 2, p 277-280, March-April, 1984. 2 Fig, 3 Tab, 20 Ref.

Descriptors: *Arsenite, Water analysis, Atomic absorption spectrophotometry.

Arsenite-but not arsenate, methylarsonic acid, or dimethylarsinic acid-is extracted from water samples by 5 mL of a 0.01M hexane solution of sec-dibutylthiophosphate. A 10 microL aliquot of the extract is injected into an atomic absorption spectrometer with a graphic furnace for the determination of arsenic. The calibration curve is linear to 1500 ng As. Quantities of arsenic as low as 100 ng As (0.2 ppb As when contained in 500 mL) can be confidently determined. The method was tested with natural river water and synthetic river water. The relative standard deviations associated with the recoveries of arsenite from natural water and synthetic river water spiked with arsenite range from 4.8 to 8.0%. Ten to 15 arsenite determinations can be completed in 1 h. (Author's abstract)
W84-04032

SAMPLING STRATEGY FOR RIVER POLLUTANT TRANSPORT,
Corps of Engineers, Buffalo, NY. Buffalo District.
S. M. Yaksich, and F. H. Verhoff.
Journal of Environmental Engineering, Vol. 109, No. 1, p 219-231, February, 1983. 3 Fig, 5 Tab, 7 Ref, 1 Append.

Descriptors: *Sampling strategy, *River flow, *Pollutant transport, Event response rivers, Stable response rivers, Suspended sediments, Phosphorus, High flow.

Estimates of the amount of pollutants which are carried by rivers from land sources to receiving water bodies are calculated from measurements of river flow rate and pollutant concentration. River flow can be measured frequently, but pollutant concentration will usually be sampled infrequently during the period of transport. A strategy is developed for sampling the pollutant concentration so that the errors in the transport estimates are minimal. Two types of rivers exist: event response rivers where suspended sediment concentrations and sediment adsorbed parameters increase with increasing flow; and stable response rivers where suspended sediment and adsorbed parameter concentrations do not increase with increasing flow. Each type of river requires its own sampling strategy. High flow events must be sampled on event response rivers to obtain reliable suspended sediment and total phosphorus flux estimates. The best method to calculate the flux with this data is an interval method. If these events are not sampled, fluxes will be underestimated by 15%-30%. Event sampling is not important for event response rivers which are impacted by point sources. For stable response rivers and parameters which do not change with flow, event sampling is not required. ANALYSIS OF TETRAHYDROTHIOPHENE IN WATER BY HEADSPACE HIGH-RESOLUTION GAS CHROMATOGRAPHY-MASS SPECTROMETRY,
Istituto di Ricerche Farmacologiche Mario Negri, Milan (Italy). Lab. of Environmental Pharmacology and Toxicology.
G. Carlucci, L. Airoldi, and R. Fanelli.
Journal of Chromatography, Vol. 287, No. 2, p 425-428, April, 1984.

Descriptors: *Tetrahydrothiophene, Sulfur compounds, Water pollution, Leachates, Gas chromatography.

Tetrahydrothiophene (THT) is widely used as a warning odorant for odorless fuel, city and natural gases and recently also for herbicides. Headspace gas chromotography was developed to monitor THT contamination of soil and spring-waters surrounding an area where a container had been incorrectly disposed. The procedure is highly sensitive to quantitate THT in water. The method appears to be useful for detecting water contamination by THT at levels as low as 10 ng/ml. (Murphy-IVI)
W84-04052

DETERMINATION OF TRACE LEVELS OF HEAVY METALS IN WATERS BY EXTRACTION WITH AMMONIUM TETRAMETHYLENEDITHIOCARBAMATE AND HEXAMETHYLENEAMMONIUM HEXAMETHYLENEDITHIOCARBAMATE INTO XYLENE FOLLOWED BY INDUCTIVELY-COUPLED PLASMA EMISSION SPECTROMETRY,
National Research Inst. for Pollution and Resources, Ibarkai (Japan).
H. Tao, A. Miyazaki, K. Bansho, and Y. Umezaki.
Analytica Chimica Acta, Vol. 156, p 159-168, 1984. 2 Fig, 5 Tab, 15 Ref.

Descriptors: *Pollutant identification, *Trace metals, *Metals, *Water analysis, Heavy metals, Spectrometry, Plasma emission spectrometry, Extraction, Sea water, Rivers.

The usefulness of extraction with ammonium tetramethylenedithiocarbamate (APDC)/hexamethyleneammonium hexamethylenedithiocarbamate (HMAHMDC)/xylene extraction system for the determination of ng/ml levels of metals in natural waters is demonstrated. Determinations of cadmium, copper, chromium, cobalt, iron, manganese, molybdenum, nickel, lead, vanadium, and zinc are described in river and sea water using inductively-coupled plasma emission spectrometry following the extraction step. The main advantages of the method are the simultaneous extraction of the metals in a single extract and simultaneous multi-element measurements by direct introduction of the organic phase into the plasma, without back-extraction or evaporation of the extract which is liable to increase contamination and losses by adsorption or evaporation. The limits of detection of the method range from 0.017 ng/ml (cadmium) to 0.5 ng/ml (lead). Nitric acid and ammonia solution were super-special grade and HMAHMDC was used without purification. If these reagents are purified, the blank will be decreased and better detection limits will be achieved. With 100-fold concentration factors, calibration graphs are linear up to 30 ng/ml or more. (Baker-IVI)

ATOMIC ABSORPTION SPECTROMETRIC DETERMINATION OF ARSENIC AND SELENIUM IN MINERAL WATERS BY ELECTROTHERMAL ATOMIZATION,
Ljubljana Univ. (Yugoslavia). Dept. of Chemistry and Chemical Technology.
V. Hudnik, and S. Gomiscek.
Analytica Chimica Acta, Vol. 157, No. 1, p 135-142, February, 1984. 6 Fig, 4 Tab, 21 Ref.

Descriptors: *Pollutant identification, Water analysis, Arsenic, Selenium, Minerals, Electrothermal atomization, Atomic absorption spectrometry, Spectrometry, Mineral water, Slovenia, Yugoslavia.

The determination of arsenic and selenium by electrothermal atomic absorption spectrometry is complicated by interferences because of the uncontrollable volatility of arsenic and selenium compounds, especially in complex inorganic and organic matrices. Mineral waters contain alkali metals, alkaline-earth metals, sulfate, chloride, and hydrogen carbonate ios in high and changeable concentrations, whereas the concentrations of arsenic and selenium are normally very low. Arsenic and selenium are separated from the macrocomponents by co-precipitation in hydrated iron (III) oxide. The precipitate is dissolved in 0.2 M sulfuric acid for injection. The detection limits are 0.2 and 0.5 micrograms/l for arsenic and selenium, respectively. The proposed method was used in the analysis of some mineral waters from Slovenia (Yugoslavia). (Baker-IVI)
W84-04060

SEPARATION OF TELLURIUM(IV) FROM WATER AND SEA WATER BY FLOTATION WITH HYDRATED IRON(III) OXIDE,
Okayama Univ., Kurashiki (Japan). Inst. for Agricultural and Biological Sciences.
S. Nakashima, and M. Yagi.
Analytica Chimica Acta, Vol. 157, No. 1, p 187-191, February, 1984. 1 Tab, 28 Ref.

Descriptors: *Pollutant identification, *Trace elements, *Tellurium, Atomic absorption spectrometry, Spectrometry, Flotation, Separation, Water analysis, Seawater.

A flotation separation method is described for determining sub-microgram levels of tellurium(IV) from 1 liter samples of water and sea water. Tellurium(IV) is coprecipitated with hydrated iron(III) oxide at pH 8-9. The precipitate is floated with the aid of surfactant solutions and small nitrogen bubbles, separated and dissolved in dilute hydrochloric acid. Tellurium is then converted to hydrogen telluride with sodium tetrahydroborate and measured by atomic absorption spectrometry. Recovery of added tellurium (0.4 and 0.8 micro g/l) was about 83%. The time required for the preconcentration is 30 min per sample, including 15 min stirring. The atomic absorption measurement of hydrogen telluride is rapid and sensitive. (Baker-IVI)

CALIBRATION AND APPLICATION OF QUAL-II TO THE LOWER WINOOSKI RIVER,
Massachusetts Univ., Amherst. Dept. of Environmental Engineering.
J. Van Benschoten, and W. W. Walker, Jr.
Water Resources Bulletin, Vol. 20, No. 1, p 109-117, February, 1984. 5 Fig, 2 Tab, 17 Ref.

Descriptors: *Water quality, *Computer models, *QUAL-II, *Lower Winooski River, *Vermont, Simulation, Phosphorus, Algae, Dissolved oxygen, Nitrogen compounds, Nutrients, Dam effects.

A modified version of the QUAL-II water quality simulation model is calibrated and applied to the Lower Winooski River, Vermont. The Winooski River flows westerly through the Green Mountains to Lake Champlain. In constrast to the upper basin, which is predominantly rural, the final 32 km, the Lower Winooski has a population of about 90,000. Waste discharges from seven municipalities and one industry enter the Lower Winooski. There are two dams on the Lower Winooski for peak power generation. Several structural modifications are made in the model to improve water quality simulations in rivers impacted by algal growth; these include the addition of organic nitrogen and organic phosphorus compartments and provision for algal uptake of ammonia and/or nitrate nitrogen. The model is interfaced with statistical programs which facilitate tabulation, display, and analysis of observed and predicted concentrations. The model is calibrated and tested against data from two intensive water quality surveys. In applying the revised QUAL-II model to the Lower Winooski River, good agreement is evident between observed and predicted water quality constituents. From a water quality management standpoint, use of the model has helped in defining the importance of algae and point-source phosphorus inputs as factors influencing the Lower Winooski's dissolved oxygen regime. ENUMERATION OF BACTEROIDES FRAGILIS GROUP ORGANISMS FROM SEWAGE AND NATURAL WATERS,
University of Wales Inst. of Science and Technology, Cardiff. Dept. of Applied Biology.
K. Allsop, and D. J. Stickler.
Journal of Applied Bacteriology, Vol. 56, No. 1, p 15-24, February, 1984. 8 Tab, 30 Ref.

Descriptors: *Bacteroides, *Bacterial analysis, *Water analysis, *Wastewater analysis, Feces, Indicator organisms, Coliforms, Membrane filtration.

The Bacteroides fragilis group (BFG) contains obligately anaerobic, Gram negative, non-motile, non-sporing bacteria. These species, the most numerous bacteria in human feces, are also known to occur in the intestinal tract of some warm blooded animals. Their presence in human feces in numbers approximately 100-fold greater than those of Escherichia coli suggests that Bacteroides spp. might be an alternative to coliform organisms as indicators of fecal contamination of water. A membrane filtration technique has been developed for the enumeration of BFG organisms from sewage and natural waters. The method used Wilkins and Chalgren agar medium supplemented with gentamicin, penicillin, aesculin and ferric ammonium citrate. Membrane filters with 0.22 micro m pores were significantly more efficient than those with 0.45 micro m pores in the isolation of BFG. A preliminary incubation period of 4 h at 30 C prior to 44 h at 37 C yielded significantly higher numbers of BFG than direct incubation at 37 C for 48 h. (Moore-IVI)

INDIRECT DETERMINATION OF CYANIDE IN WATER BY ATOMIC-ABSORPTION SPECTROPHOTOMETRY,
Shanghai Normal Univ. (China). Dept. of Chemistry.
B.-X. Xu, T.-M. Xu, and Y.-Z. Fang.
Talanta, Vol. 31, No. 2, p 141-143, February, 1984. 2 Fig, 3 Tab, 11 Ref.

Descriptors: *Cyanide, *Atomic absorption spectrophotometry, Lead, Anions, Industrial wastewater, Huang Pu River, China.

The standard method for determining trace cyanide in water is colorimetry, but it involves preseparation and use of a carcinogenic reagent (benzidine). An indirect method for determination of trace cyanide in water by atomic-absorption spectrophotometry is described. Cyanide forms a stable complex anion with Pd in alkaline solution. This complex anion can form an ion-association complex with tetra-alkylammonium ions which can be extracted into n-butyl alcohol with an efficiency higher than 90%. The extract can be analysed directly for palladium (and hence indirectly for cyanide) by flame atomic-absorption spectrophotometry. The detection limit for cyanide by this method is 0.1 microg/ml in the n-butyl alcohol extract. Beer's law is obeyed for 0.13-9 microg of CN(-) per ml of n-butyl alcohol. Several foreign ions do not interfere. (Murphy-IVI)

INVESTIGATIONS OF THE ECOTOXICOLOGICAL EFFECT OF A HERBICIDE IN AN AQUATIC MODEL ECOSYSTEM; II. FOOD CHAIN SIGNIFICANCE AND PESTICIDE BALANCE (UNTERSUCHUNGEN ZUR OKOTOXIKOLOGISCHEN WIRKUNG EINES HERBIZIDS IN EINEM AQUATISCHEN MODELLOKOSYSTEM; II. NAHRUNGSKETTENPROBLEME UND SCHADSTOFFBILANZIERUNG),
Technische Univ., Berlin (Germany, F.R.). Inst. fuer Technischen Umweltechutz.
V. G. Gunkel.
Archiv fur Hydrobiologie, Vol. 1, p 130-168, Stuttgart, January, 1984. 16 Fig, 6 Tab, 60 Ref.

Descriptors: *Herbicides, *Toxicity, *Ecosystems, Atrazine, S-triazine, Bioaccumulation, Phytoplankton, Benthic fauna, Fish, Fate of pollutants, Food chains.

Herbicides are currently extensively used throughout developing countries. Although it is known what effects herbicides have on the specific target species, the general effects to the ecosystem is not widely studied. To determine the bioaccumulation of the herbicide (atrazine, s-triazine), a small pond was investigated during a vegetation period. The herbicide residues were determined in organisms at different trophic levels (phytoplankton, macrophytes, zooplankton, and fishes). High bioconcentration factors occur in phytoplankton during periods of small phytoplankton biomasses. Organisms of high trophic levels only reach small bioconcentration factors, and no food-chain effect can be observed under consideration of benthic and pelagic consumers. The phytoplankton accumulates atrazine to a varying level, ranging from 27 up to 1200. The level of the atrazine residue is not closely correlated with the phytoplankton species. High bioconcentration factors occur only in small phytoplankton biomasses. Daphnia pulicaria (Cladocera), a filtering zooplankton organism, accumulates less atrazine than phytoplankton; bioconcentration factors are less than 16. In water-free, dried bottom which consists mainly of organic material, concentration factors of 20 to 45 are observed. Larvae of sediment-eating Chironomus possess atrazine residues smaller than those found in the sediment with bioconcentration factors of 1.4 to 4.8. Fishes as final consumers of the experimental system possess only small bioconcentration factors, less than 9. Most of the herbicide is dissolved in the water with other losses to plants, animals, the sediment, the air and outflow. At the end of the experiment atrazine is distributed between the compartments of the pond system - water, sediment, atmosphere, phytoplankton, and zooplankton in the ratio 11400:660:5:2:1. SEASONAL CHANGES IN THE CONCENTRATION AND COLOUR OF HUMIC SUBSTANCES IN SOME AQUATIC ENVIRONMENTS,
Laval Univ., Quebec. Dept. of Soil Science.
S. A. Visser.
Freshwater Biology, Vol. 14, No. 1, p 79-87, February, 1984. 5 Fig, 3 Tab, 37 Ref.

Descriptors: *Concentration, *Color, *Humic acids, Aquatic environment, Organic matter, Fulvic acids, Precambrian shield, Quebec.

Over 40% of the organic matter present in natural waters consists of complex heterogenous yellow or brown acidic polymers collectively known as humic matter. Between February and September 1974, concentrations of fulvic and humic acids in waters from a cryoboreal region of the Precambrian Shield in Quebec varied between 0.5-6.1 mg/l and 0.1-6.5 mg/l respectively. Whereas the fulvic acids usually remained relatively constant during this period, humic acids showed appreciable increases. The number and weight average molecular weights of the fulvic acids (approximately 5000 and approximately 22,000 daltons respectively) were lower than those of the humic acids (approximately 20,000 and approximately 75,000 respectively). The average molecular weight of the aquatic humic matter often decreased during late summer and early autumn. During spring floods the molecular weight of fulvic acids increased and that of humic acids declined. Because the aquatic humic acids were more intensely colored than fulvic acids, they contributed more than 30% of the color of the water even though they accounted for only 15% of the concentration of humic matter. The color intensity of both fulvic and humic acids generally appeared to increase during the latter part of the summer, when there was normally a decrease in the value of the color quotient (E4/E6 ratio), indicating the accumulation in the waters of more humified material. DISSOLVED HEAVY METALS IN A LACUSTRINE MINE TAILINGS DEPOSIT-BUTTLE LAKE, BRITISH COLUMBIA,
British Columbia Univ., Vancouver. Dept. of Oceanography.
T. F. Pedersen.
Marine Pollution Bulletin, Vol. 14, No. 7, p 249-254, 1983. 2 Fig, 2 Tab, 10 Ref. Natural Sciences and Engineering Research Council of Canada grant UO139.

Descriptors: *Heavy metals, *Mine wastes, *Lacustrine wastes, *Buttle Lake, *British Columbia, Zinc, Copper, Cadmium, Lakes, Open-pit mining, Mine drainage, Pollution load, Sedimentation.

The degree of post-depositional (diagenetic) reactivity of submerged mine tailings in fresh water in Buttle Lake, British Columbia, is assessed by inves-

tigating the distribution of Zn, Cu, Cd, Mn and Fe in interstitial water profiles collected from the upper meter of the tailings deposit and from proximal natural sediments. These dissolved Zn, Cu and Cd concentrations indicate that the tailings are not releasing heavy metals to the overlying lake water at present, and there is no evidence to suggest that significant oxidation is occurring in the deposit. The lake waters are enriched in metals from surface drainage, however, while pore waters in natural sediments are heavy-metal-depleted. Diffusion into the natural sediments therefore tends to buffer the lacustrine metal load, but only to a very limited extent. Modern open-pit mining operations often generate large quantities of mill tailings. Terrestrial disposal of this waste is expensive and may have serious environmental consequences, including surface water contamination from acidic drainage enriched in leached heavy metals. Submarine disposal, in contrast, is relatively inexpensive and has often been justified on the grounds that tailings have low chemical reactivity in marine or lacustrine waters. As a result coastal and inland waters in many areas of the world are being used increasingly as tailings disposal sites. However, recent field and laboratory studies have demonstrated that under certain conditions, tailings do release dissolved metals upon exposure to seawater. (Murphy-IVI)

LEVELS OF ORGANOCHLORINE COMPOUNDS IN AN INLAND SEAL POPULATION IN EASTERN FINLAND,
Joensuu Univ. (Finland). Dept. of Biology.
E. Helle, H. Hyvarinen, H. Pyysalo, and K. Wickstrom.
Marine Pollution Bulletin, Vol. 14, No. 7, p 256-260, 1983. 2 Fig, 5 Tab, 17 Ref.

Descriptors: *Organochlorine compounds, *Seal populations, *Finland, Saimaa seals, Polychlorinated biphenyls, DDT, Chlordane, Chlorophenol, Population exposure, Ecological effects, Water pollution effects, Bioaccumulation, Lake Saimaa.

The Saimaa seal population has decreased rapidly in recent decades and the population is now estimated to be only 100-odd individuals. Until now the possible role of environmental toxins in the reduction of the Saimaa seal population has remained undetermined. Fourteen Saimaa ringed seals (Phoca hispida saimensis) were studied for PCB, DDT, chlordane and chlorophenol compounds in blubber, liver, muscle, heart and kidney in Lake Saimaa, eastern Finland, in 1977-1981. Both PCBs and total DDT increased on average from a good 5 mg/kg in extractable fat of blubber in a new-born to a good 65 mg/kg in sexually mature specimens, the maximum being 93 and 104 mg/kg respectively. Concentrations of PCBs and tDDT in blubber and liver were most clearly dependent on the age and weight of the seal. Chlordanes were found in all 14 specimens (mean 0.59 mg/kg in blubber), trichlorophenol in one, tetrachlorophenol in two and pentachlorophenol in all three specimens studied. Although some of the Saimaa seals had reached quite high levels of both PCBs and tDDT, the present results do not indicate that the steady decrease of the Saimaa seal population during the last two decades would have been caused by these toxins, at least not in isolation. (Murphy-IVI)

HEAVY METALS IN MARINE NEMATODES: UPTAKE, TISSUE DISTRIBUTION AND LOSS OF COPPER AND ZINC,
Newcastle upon Tyne Univ. (England). Dept. of Zoology.
R. Howell.
Marine Pollution Bulletin, Vol. 14, No. 7, p 263-268, 1983. 3 Fig, 2 Tab, 18 Ref.

Descriptors: *Heavy metals, *Nematodes, *Tissue analysis, *Copper, *Zinc, Bioindicators, Hypodermis, Cuticle, Fate of pollutants, Budle Bay, Blyth estuary, Estuaries, Bioaccumulation, Seawater, England.

The uptake and loss of copper and zinc was studied in two species of marine nematode from a non-polluted site and in one species from a polluted site. Copper and zinc concentrations were measured during and after accumulation from seawater in six different tissues of the nematodes. The rapid uptake and loss of both copper and zinc by the cuticle of all three groups suggests that the primary event is surface adsorption. The role of the 'other tissues' is difficult to assess. This group included the hypodermis which is known to be highly metabolically active and as well as secreting the cuticle is thought to be the site of many physiological processes in the body. As such it represents a highly specific target for toxicants of the heavy metal type, which are known to interfere with a wide variety of enzymes and cellular systems. (Murphy-IVI)

OLD CANNERY WASTES, A POTENTIAL SOURCE OF TRACE METALS IN THE MARINE ENVIRONMENT,
Northwest Consultant Oceanographers, Inc., Seattle, WA.
L. C. Loehr, and E. E. Collias.
Marine Pollution Bulletin, Vol. 14, No. 10, p 392-394, 1983. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Trace metals, *Cannery wastes, *Marine environment, Lead, Zinc, Mussels, California, Monterey Bay, Cypress Point, Cannery Row, Wastewater outfall, Bioaccumulation, Fate of pollutants, Wastewater pollution.

High levels of lead and zinc have been measured in the California Mussel Mytilus californianus taken from southern Monterey Bay as part of the California State Mussel Watch program. The levels of lead and zinc increase steadily from Cypress Point towards Cannery Row. The California State Water Resources Control Board (which funded but did not conduct the State Mussel Watch) has attributed the high levels to heavy metals contributed by sewage. The state mussel watch data reports have not considered the historic canning wastes from more than 30 canneries along Cannery Row as a possible source of trace metals. Leachates from old cannery wastes may be a major source of lead and zinc in mussels in southern Monterey Bay and must be considered in assessing any data from the State Mussel Watch program. TOTAL MERCURY, METHYL MERCURY AND SULPHIDE IN RIVER CARRON SEDIMENTS,
Leicester Polytechnic (England). School of Chemistry.
P. J. Craig, and P. A. Moreton.
Marine Pollution Bulletin, Vol. 14, No. 11, p 408-411, 1983. 2 Fig, 1 Tab, 8 Ref.

Descriptors: *Mercury, *Methyl mercury, *Sulfide, *Carron River, *Sediments, Wastewater disposal, Fate of pollutants, Estuaries, Scotland.

Methyl mercury levels are controlled more by the sulfide content in sediments than by factors such as total mercury levels or organic content. Total mercury, methyl mercury and sulfide contents of River Carron sediments (Lothian, Scotland) have been determined. Total mercury concentrations are comparable to other mercury polluted estuaries in the UK, but the methyl mercury values for low-sulfide Carron sediments are generally higher. The methyl mercury levels are initially in direct proportion to the sulfide concentrations of the sediments but beyond sulfide concentrations of 1.8 mg/g the methyl mercury levels decline sharply. (Murphy-IVI)

AERIAL FLUX OF PARTICULATE HYDROCARBONS TO THE CHESAPEAKE BAY ESTUARY,
Old Dominion Univ., Norfolk, VA. Dept. of Oceanography.
D. B. Webber.
Marine Pollution Bulletin, Vol. 14, No. 11, p 416-421, 1983. 2 Fig, 1 Tab, 47 Ref. EPA grant X00322501.

Descriptors: *Particulate matter, *Hydrocarbons, *Chesapeake Bay, *Estuaries, Deposition, Municipal wastewater, Water pollution, Air pollution effects, Fate of pollutants, Air pollution.

To delineate the magnitude of the atmospheric input of high molecular weight hydrocarbons, deposition rates were measured over a 15 month period at four stations in south-eastern Virginia surrounding the lower Chesapeake Bay. A nearly linear trend of atmospheric particulate deposition was recorded. Deposition rates at the urban station (195 microg/sq m/day) were approximately three times greater than those recorded for nonurban and coastal locations (mean value 69 microg/sq m/day). The increased levels at the urban location were attributed to localized source inputs. Anthropogenic hydrocarbons accounted for approximately 50% of the total deposition at all stations. Significant biogenic inputs were indicated by the odd/even n-alkane distribution. A minimum flux to the water surface, based on mean nonurban deposition rates (24 mg/yr), indicated an annual particulate hydrocarbon flux of +275 metric tons. Little information is available for the comparison of additional source inputs; however, the data reported here indicate that the aerial deposition of hydrocarbons is of the same order of magnitude as the input from municipal wastewater facilities and accidental discharge and is a potentially signficant source of hydrocarbon pollution to the Chesapeake Bay Estuary. TRACE METAL DISTRIBUTIONS IN SAINT JOHN HARBOUR SEDIMENTS,
Department of Fisheries and Oceans, St. Andrews (New Brunswick).
S. Ray, and S. D. MacKnight.
Marine Pollution Bulletin, Vol. 15, No. 1, p 12-18, January, 1984. 8 Fig, 4 Tab, 15 Ref.

Descriptors: *Trace metals, *Saint John Harbor, *Sediments, Sedimentation, Dredging, Estuaries, Distribution, New Brunswick, Canada, Anthropogenic input.

The Saint John River has the largest estuary in the Province of New Brunswick, Canada. Its harbor is extensively used during the whole year and requires regular maintenance dredging. The open-water disposal site for the dredged material is situated off Black Point. The concentration and areal distribution of selected trace metals (Cu, Zn, Pb, Cd, Mo, Ni, Mn and Hg) in surficial sediments of Saint John Harbor, were studied to determine the extent of anthropogenic input and to estimate the effects of dumping dredged material in the outer harbor. Hg and Cd are of special concern, since the disposal of dredge material containing these two elements is regulated under the Ocean Dumping Control Act. The concentrations of all metals are low: Cu 16, Zn 53, Pb 24, Cd 0.16, Mo 3, Ni 16, Mn 296 and Hg 0.04 microg/g. Hg and Cd levels in sediment are well below the permissible limits of 0.75 and 0.6 microg/g, respectively, set by the Ocean Dumping Control Act. The mean concentrations of trace elements are similar to the low mean values in the unpolluted Bay of Fundy. There is an overall decline in concentrations of metals in the sediments from the inner to the outer harbor. Comparison of the metal levels in the sediments from different areas within the harbor indicate that there is a detectable anthropogenic input in the Courtenay Bay area. Trace metal levels at the dumpsite are significantly lower than in the Courtenay Bay area, where the bulk of the dredged material originates. (Murphy-IVI)

SURFACE-WATER QUALITY IN THE CAMPBELL CREEK BASIN, ANCHORAGE, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
T. P. Brabets, and L. A. Wittenberg.
USGS Water-Resources Investigations Report 83-4096, 1983. 28 p, 20 Fig, 12 Tab, 11 Ref.

Descriptors: *Urban hydrology, *Water quality, Urban runoff, Streamflow, *Alaska, Anchorage, Campbell Creek basin.

Four streams in the Campbell Creek Basin were sampled during different flow conditions for an 18-month period. North Fork Campbell and South Fork Campbell Creeks drain areas virtually undisturbed by man's activities. The other two streams, Little Campbell Creek and the main stem Campbell Creek, drain areas that have been urbanized. The water from South Fork Campbell and North Fork Campbell Creeks is of good quality and does not adversely affect the water quality of the main stem Campbell Creek. Little Campbell Creek, which has been affected by urbanization, impacts the water quality of Campbell Creek during low-land snowmelt periods when discharges from South Fork Campbell and North Fork Campbell Creeks are small. High concentrations of suspended sediment in Campbell Creek may be contributed by Little Campbell Creek. Fecal-coliform bacteria concentrations are highest at Little Campbell Creek and probably account for most of the high coliform concentrations at Campbell Creek. (USGS)

SOUTH JEFFERSON STREAM QUALITY ASSESSMENT PROGRAM,
Clarkson Coll. of Technology, Potsdam, NY. Dept. of Civil and Environmental Engineering.
J. V. DePinto.
Report, Temporary State Commission on Tug Hill, Watertown, N.Y., November, 1977. 19 p, 1 Fig, 4 Tab, 2 Ref.

Descriptors: *Water quality, *Stream pollution, *Chemical analysis, *Stream profiles, *Water sampling, *Bacterial analysis, Stream biota, Watersheds, Large watersheds, Streamflow, Eutrophication, Nutrients, Land use, Acidity, Acid streams, Water temperature, Alkalinity, Dissolved oxygen, Biological oxygen demand, Dissolved solids, Suspended solids, Phosphorus, Coliforms, Ammonia, Nitrogen, Nitrates.

This program was designed to provide an educational experience for a group of supervised Jefferson County High School students and to obtain specific data which will allow relationships to be seen between the Lake Ontario eastern coastal zone and upland watersheds on Tug Hill. The program will also serve as a benchmark for future studies by providing information by which to gauge future water quality, and the information is available to local towns. The students performed both qualitative observation of some of the important streams and periodic quantitative analysis of stream water quality by laboratory testing of water samples collected at nine sites. The following parameters were tested: pH, alkalinity, temperature, dissolved oxygen, BOD5, suspended and dissolved solids, ammonia-nitrogen, nitrate-nitrogen, total phosphorus, and total coliform. Stream flow was estimated, too. The overall water quality of the South Jefferson County streams sampled in the study is good, and, discounting the presence of toxic substances, these streams should support a healthy, diverse aquatic community. In general, the downstream water quality appears to be slightly lower (increase in BOD5, solids, and total phosphorus). The nutrient loadings to Lake Ontario are such that the nearshore bays receiving these nutrients might eventually suffer the effects of eutrophication. The major land use impact on stream water quality appears to be the effect of the village of Adams on Sandy Creek. (Fazio-Omniplan)

ADDENDUM TO THE SURFACE WATER QUALITY REPORT,
Disko (M.) Associates, Union, NJ.
M. Disko, and T. Marturano.
Report, September 1981. 344 p, 73 Fig, 103 Tab.

Descriptors: *Surface water, *Surface-groundwater relations, *Computers, *Computer programs, *Water quality data, *Stream profiles, Stream discharge, Streams, Catchment areas, Wastewater disposal, Water quality, Dissolved solids, Data analysis.

The preliminary report in 1978 contained an analysis of only five of 21 parameters actually measured, because of a time constraint imposed by problems with the state's STORET computer system. Since there was not statistical analysis of the data available, the preliminary report contained only information pertaining to the percentage of time each station violated a state standard. Analyses in the report should not be correlated with results in the 1978 report because numerous data corrections as well as three months of additional testing changed the statistical averages. Instead of using STORET's analytical capabilities, a more flexible program, Statistical Analysis Systems, was used to analyze the data. Twelve of the fifty-seven stations have been designated as trout maintenance waters. There is an increase in the dissolved oxygen standard from five to six mg/l. Other standards at the time of the sampling were turbidity, pH, fecal coliform, total dissolved solids, and total phosphorus. Since Ocean County soils are naturally acidic, the average pH of the area is well below the 6.5 standard. The total dissolved solids standard for these water is 133 percent of the background value. The water quality in Crosswicks Creek was found to be one of the poorest in the county. Almost every parameter recorded its highest concentration at this station, sometimes several times larger than the county average. In general, it appears that poorer water quality is in the north and western parts of the county. (Garrison-Omniplan)

VARIABILITY OF SURFACE RECHARGE AND ITS EFFECTS ON GROUNDWATER IN SUFFOLK COUNTY, LONG ISLAND,
Cornell Univ., Ithaca, NY. Center for Environmental Research.
W. H. Brutsaert, and T. S. Steenhuis.
Available from the National Technical Information Service, Springfield, VA 22161, as PB84 154376, Price codes: A02 for paper copy, A01 for microfiche. Completion Report, September, 1983. 9 p, 4 Fig, 4 Ref. Project No. OWRT A-095-NY (1), Contract/Grant No. 14-34-0001-2134.

Descriptors: Groundwater pollution, Infiltration, Spatial variability, Unsaturated flow, Long Island, Porous media flow, Path of pollutants, *New York, Suffolk County, Groundwater recharge, Soil contamination.

The overall objective was to gain more insight in the variability of downward movement of water, which is the main carrier agent of pollutants in the soil. The study focused on Eastern Long Island where conditions of groundwater pollution are especially severe. For this purpose the infiltration properties of a Haven loam were determined in the laboratory by means of a newly-designed vertical capillary rise apparatus on 180 disturbed field samples of topsoil and subsoil. The experimental data were first processed by means of several concise formulations for sorption; measured and determined for each sample were rate of wetting front advance, three forms of sorptivity and four diffusivities. Subsequently a geostatistical analysis was performed and applied to the subsoil sorptivity data. The understanding gained in this project will be incorporated in predictive modeling techniques for the transport of toxic chemicals to the groundwater.

VIRUS MOVEMENT IN SOIL DURING SATURATED AND UNSATURATED FLOW,
Agricultural Research Service, Durant, OK. Water Quality and Watershed Research Lab.
J. C. Lance, and C. P. Gerba.
Applied and Environmental Microbiology, Vol. 47, No. 2, p 335-337, February, 1984. 1 Fig, 3 Tab, 13 Ref. EPA project R-805,292.

Descriptors: *Viruses, *Soil water, *Saturated flow, *Unsaturated flow, Soil columns, Wastewater disposal, Water reuse, Poliovirus, Soil absorption capacity.

Virus movement in soils has received much attention because land application of wastewater offers a unique opportunity to turn the wastewater into a valuable water resource while minimizing the pollution of surface water. Virus movement in soil during saturated and unsaturated flow was compared by adding poliovirus to sewage water and applying the water at different rates to a 250-cm-long soil column equipped with ceramic samplers at different depths. Movement of viruses during unsaturated flow of sewage through soil columns was much less than during saturated flow. Viruses did not move below the 40-cm level when sewage water was applied at less than the maximum infiltration rate; virus penetration in columns flooded with sewage was at lease 160 cm. Therefore, virus movement in soils irrigated with sewage should be less than in flooded groundwater recharge basins or in saturated soil columns. Management of land treatment systems to provide unsaturated flow through the soil should minimize the depth of virus penetration. Differences in virus movement during saturated and unsaturated flow must be considered in the development of any model used to simulate virus movement in soils. (Murphy-IVI)

PENETRATION OF DIFFERENT HUMAN PATHOGENIC VIRUSES INTO SAND COLUMNS PERCOLATED WITH DISTILLED WATER, GROUNDWATER, OR WASTEWATER,
Bundesgesundheitsamt, Berlin (Germany, F.R.). Inst. fuer Wasser-, Boden- und Lufthygiene.
H. Dizer, A. Nasser, and J. M. Lopez.
Applied and Environmental Microbiology, Vol. 47, No. 2, p 409-415, February, 1984. 7 Fig, 22 Ref.

Descriptors: *Viruses, *Sand columns, *Percolating water, *Distilled water, *Groundwater, *Wastewater, Water reuse, Decontamination, Drinking water, Adsorption, Tertiary effluent, Groundwater recharge, Infiltration, Percolation rate.

Thanks to the adsorption processes in aquifers and to the metabolism of their microflora, groundwater, if contaminated, has the tendency to regenerate itself. This makes an underground recharge of tertiary treated wastewater an ideal last step before the wastewater is reused. The adsorption of several enteroviruses and rotavirus SA11 to sand from an aquifer in the Federal Republic of Germany was estimated in sand-filled columns loaded with ca. 107 PFU and run at a velocity of 2.5 m/day for 12 h. After either distilled water, groundwater, secondary effluent, or tertiary effluent was percolated, the sand core was slowly extruded out of the column and cut in 1-cm slices. The slices were eluted with nutrient broth, and the amount of viruses in the broth was estimated. The best adsorption was promoted by groundwater and tertiary effluent, followed by distilled water and secondary effluent. Similar experiments, carried out at different percolation rates, indicated that a 50-day

underground stay of recharged water probably suffices to eliminate viruses in the groundwater-recharged tertiary effluent. However, when viruses and sand were incubated in the presence of the surfactants sodium dodecyl sulfate, nonyl phenol, dodigen 226, or alkylbenzylsulfonate, the adsorption of the viruses was substantially diminished. Experiments in the presence of nonyl phenol seem to indicate that hydrophobic interactions are involved in the adsorption of viruses to sand. (Murphy-IVI)

DISTRIBUTION FUNCTION OF HEAVY METALS IN RIVER SEDIMENT,
Nippon Inst. of Tech., Saitama. Applied Statistics Lab.
H. Nishida, and M. Miyai.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 2, p 212-219, February, 1984. 2 Fig, 2 Tab, 5 Ref.

Descriptors: *Heavy metals, *Fate of pollutants, *Sediments, Japan, Copper, Chromium, Zinc, Lead, Cadmium, Nickel, Distribution.

Random samples of unpolluted upstream and downstream sediments were obtained at 10 points from the right to left banks of each of 92 rivers in Japan. The upstream sediments were taken at unpolluted places and those downstream were taken about 1 km from the river mouth. The quantities of heavy metals soluble in hydrochloric acid were measured. In order to decide the distribution function of each heavy metal, its AIC was calculated. The AIC is a statistical decision procedure for model fitting. Each heavy metal of river sediment derived from a single source was found to be distributed lognormally. (Baker-IVI)

RESIDUES OF 4-CHLORO-1-(2,4-DICHLOROPHENOXY)-2-METHOXYBENZENE (TRICLOSAN METHYL) IN AQUATIC BIOTA,
Tokyo Metropolitan Research Lab. of Public Health (Japan).
T. Miyazaki, T. Yamagishi, and M. Matsumoto.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 2, p 227-232, February, 1984. 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Fate of pollutants, *Fish, *Organic compounds, Triclosan methyl, Fish, Oysters, Clams, Mussels, Tama River, Tokyo Bay, Japan.

A total of 14 samples (10 fish and four shellfish) was collected at 11 sampling locations in the Tama River and Tokyo Bay (Japan) during September to October 1981. Triclosan methyl was found in 13 of the 14 samples, detected in all freshwater fish, and ranged from 1-38 ppb. Triclosan methyl is a methyl ether deriviative of triclosan, a broad spectrum antibacterial agent used widely in varied products such as deodorant, surgical scrub preparations, and medicated cosmetics. The concentrations in the fish samples increased downstream. Triclosan methyl residue was also found in shellfish taken from Keihinjima along Tokyo Bay with short necked clams having 3 ppb; thin shelled surf clams, 13 ppb; oysters, 13 ppb and blue mussel, 20 ppb. COOLING WATER SUPPLY DISPOSAL IN COASTAL AQUIFER,
Dames and Moore, Honolulu, HI.
M. R. Fujioka, and A. K. Runchal.
Journal of Energy Engineering (ASCE), Vol. 109, No. 2, p 88-102, June, 1983. 10 Fig, 2 Tab, 9 Ref.

Descriptors: *Cooling water, *Disposal wells, *Coastal aquifer, Coupled fluid flow, Heat transport, Mass transport, Groundwater, Water reuse, Mathematical models, Geohydrology, Permeability coefficient.

The analysis of cooling water supply and thermal effluent disposal within a coastal aquifer requires the solution of the coupled transport equations for groundwater, heat, and mass transfer. A general numerical model for these requirements was applied to assess feasibility of simultaneous cooling water supply and effluent disposal by wells. Hydraulic conductivities were calibrated using groundwater heads and flux data. Existing conditions, a Ghyben-Herzberg lens in dynamic equilibrium, were modeled, and served as initial conditions for subsequent analysis. Various injection and supply well configurations were modeled and feasible configurations were identified. A number of conclusions were developed regarding flow velocities, cross-circulation flow, hydraulic interchange with the adjacent ocean, heat removal mechanisms, effects on the fresh water lens, and ocean bottom heating. STUDY OF THE POLLUTION POTENTIAL OF LAND-SPREAD SEPTAGE,
Oregon State Univ. Extension Service, Corvallis.
J. A. Moore, and G.R. Beehler.
Journal of Environmental Health, Vol. 46, No. 4, p 171-175, January/February, 1984. 1 Fig, 1 Tab, 14 Ref.

Descriptors: *Land disposal, *Groundwater pollution, *Septage, Nitrates, Coliforms, Soil properties, Hydraulic loading.

There are two possible health hazards associated with the land spreading of septage: pathogenic and chemical contamination of surface and groundwaters. Seven plots which had not previously been treated with septage were treated with two types of domestic septage application. Four plots, receiving no more than 3,000 gal/day were intermittently loaded receiving 174,000, 169,000, 32,000 and 39,000 gallons of septage during the three year study. This represented a total nitrogen application equivalent to 2,400, 1,100, 630 and 290 lbs N/acre. Spreading nitrogen at a rate of 10,000 lbs/acre or 90 acre inch of septage over an 11 week period resulted in no evidence of penetration of fecal coliform organisms to the shallow (3 m) water table. The nitrate nitrogen increased slightly in one of the four monitoring wells, and all values were below 10 mg/l. Neither slug loading up to 4 gal/sq foot or steady intermittent loadings (up to 3,000 gal per plot/day) of septage harmed the shallow groundwater. Fecal coliform counts and nitrate nitrogen levels show the tremendous treatment capability of the sandy soil. Finer textured soils should provide a better filter and further reduce the movement of organisms and nitrate. The capacity of the soil filter can be exceeded, resulting in contamination of the groundwater. Application rate of septage should be limited depending on the characteristics of the receiver soil, so that hydraulic loading would provide unsaturated flow through the profile, allowing adequate treatment. VIRUSES IN GROUNDWATER BENEATH SEWAGE IRRIGATED CROPLAND,
Minnesota Univ., St. Paul. Coll. of Veterinary Medicine.
S. M. Goyal, B. H. Keswick, and C. P. Gerba.
Water Research, Vol. 18, No. 3, p 299-302, 1984. 6 Tab, 14 Ref.

Descriptors: *Viruses, *Wastewater irrigation, *Groundwater pollution, Wells, Spray irrigation, Land disposal, Wastewater disposal, Irrigation, Coliforms, Coxsackievirus, Water reuse, Chlorination.

The occurrence of enteric viruses in groundwater and soil was examined beneath three different sites where slow rate sewage irrigation of cropland is practiced. One site was in Lubbock, Texas where a sewage treatment plant supplies 57,000 cu m/day of secondarily treated effluent to a privately owned 3000 acre farm where the effluent is applied by flood or spray irrigation. Location two was in San Angelo, Texas where secondarily treated effluent is applied to a 640 acre farm by flood irrigation. Location three was in Muskegon, Michigan, where sewage at a rate of 105,000 cu m/day is aerated and stored in two 850 acre lagoons. The effluent is then applied to the 11,000 acre farm by 54 center-pivot spray arms at rates of up to 10 cm per week. Enteric viruses were isolated from wells beneath all sites. The lowest frequency of isolation was from wells beneath the one site practicing chlorination before application by spray irrigation. Viruses were detected in wells as deep as 27.5 m. (Baker-IVI)

STUDIES ON VINYL CHLORIDE MIGRATING INTO DRINKING WATER FROM POLYVINYL CHLORIDE PIPE AND REACTION BETWEEN VINYL CHLORIDE AND CHLORINE,
National Inst. of Hygienic Sciences, Tokyo (Japan).
M. Ando, and Y. Sayato.
Water Research, Vol. 18, No. 3, p 315-318, 1984. 9 Fig, 1 Tab, 6 Ref.

Descriptors: *Water pollution sources, *Vinyl chloride, *Pipes, *Drinking water, *Polyvinyl chloride, Pipe liners, Migration, Chemical reactions, Chlorine, Chloroacetaldehyde, Chloroacetic acid, Hydrogen ion concentration, Water conveyance.

Actual conditions under which vinyl chloride monomer (VCM) migrates into water from polyvinyl chloride (PVC) pipes and the reaction of VCM with chlorine in water are considered. In one study method, migration of VCM into water from PVC pipes was examined by sealing water in sections of PVC pipe. In the second method a few pieces of PVC pipe were sealed with water in a serum vial. Migration of VCM into water from PVC pipes could only be detected by using an apparatus that prevented volatilization of VCM and increased the surface area of the pipe wall in contact with the water. The amount of VCM which could undergo action of the chlorine in the water decreased markedly with the age of the pipes and when the pH was lowered. VCM occurred in the water and was converted to chloroacetaldehyde, chloroacetic acid and other compounds through its reaction with chlorine. The amounts of these reactants varied with the pH of the solution. (Baker-IVI)

HEAVY METALS IN THE SURFICIAL SEDIMENTS OF FONTANA LAKE, NORTH CAROLINA,
Clemson Univ., SC. Dept. of Environmental Systems Engineering.
A. R. Abernathy, G. L. Larson, and R. C. Mathews, Jr.
Water Research, Vol. 18, No. 3, p 351-354, 1984. 1 Fig, 2 Tab, 19 Ref.

Descriptors: *Heavy metals, *Lake sediments, *Fontana Lake, *North Carolina, Lakes, Sediments, Zinc, Copper, Mercury, Aluminum, Manganese, Iron, Magnesium, Minerals.

Samples of sediment were collected in the main body of Fontana Lake and near the mouths of its major tributaries. Analyses were conducted for magnesium, iron, aluminum, manganese, zinc, copper, and mercury. While the drainage area of the reservoir is primarily forested and rural without major industrial developments, manganese, copper and zinc were present in concentrations similar to areas receiving industrial pollution. Chemical analyses of pyritic materials in the watershed showed relatively high concentrations of many of the same metals. Therefore, inputs of metal compounds may be expected from lake or reservoir drainage basins with mineralized deposits. Accumulations of these metals in the sediments may pose a biological risk in the future. This may be especially important should the lake or reservoir acidity increase owing to impacts from acid precipitation upon the soft water system. (Baker-IVI)

CONTAMINATION OF AN UNCONFINED SAND AQUIFER BY WASTE PULP LIQUOR: A CASE STUDY,

Waterloo Univ. (Ontario). Dept. of Earth Sciences.
W. D. Robertson, J. F. Barker, Y. LeBeau, and S. Marcoux.
Ground Water, Vol. 22, No. 2, p 191-197, March-April, 1984. 6 Fig, 1 Tab, 5 Ref.

Descriptors: *Groundwater pollution, *Unconfined aquifers, Aquifers, Path of pollutants, Pulp and paper industry, Industrial wastes, Waste disposal, Sulfates, Chlorides, Sodium, Plumes, Lignin, Tannin.

A zone of contaminated groundwater has been identified in an unconfined sand aquifer adjacent to a pit near the town of La Tuque, Quebec into which spent pulp liquor was intermittently discharged from 1970 to 1979. The installation of multilevel piezometers has provided a cost-effective method for three-dimensional mapping and sampling of the plume in the sand. The contaminated groundwater is characterized by elevated concentrations of Na (3,000 mg/l), Cl (590 mg/l), alkalinity (2,700 mg/l), total organic carbon (2,000 mg/l), COD (10,800 mg/l), BOD (2,000 mg/l) tannin and lignin (780 mg/l), and lower sulfate (1 mg/l) compared to groundwater in the area. Contaminants such as Na(+), Cl(-), tannin and lignin appear to migrate at a rate close to the average linear groundwater velocity. Hydrodynamic dispersion has caused vertical and horizontal spreading of the contaminants and significant dilution especially near the leading edge of the plume. Other major contaminants such as sulfates and high pH are substantially attenuated, probably in part by microbially mediated processes. Some organic components also appear to be attenuated, but high concentrations of less biodegradable substances such as tannin and lignin, persist along the flow path. (Baker-IVI)

FATE AND EFFECT OF (14C)FENVALERATE IN A TIDAL MARSH SEDIMENT ECOSYSTEM MODEL,
Maryland Univ., College Park. Dept. of Entomology.
J. A. Caplan, A. R. Isensee, and J. O. Nelson.
Journal of Agricultural and Food Chemistry, Vol. 23, No. 1, p 166-171, January/February, 1984. 7 Fig, 3 Tab, 17 Ref.

Descriptors: *Pesticides, *Fenvalerate, *Tidal marshes, Fate of pollutants, Sediments, Leaching, Microorganisms, Water pollution effects, Salt marshes.

A model salt marsh ecosystem was developed and used to evaluate the fate and effect of a pesticide under simulated salt marsh conditions. Fenvalerate was used as a reference pesticide. Fenvalerate is a pyrethroid insecticide that has great potential for control of a wide range of insect pests in agriculture. Two dosages (0.2 and 1.0 ppm) of C-14 labeled fenvalerate were uniformly applied to the sediment. Additionally, a third treatment (1.0 ppm) was applied to the top centimeter of a 3-cm column to monitor the vertical movement of the compound (plus metabolites). No adverse effects of C-14 fenvalerate on heterotrophic microorganisms were observed after 7 days at any treatment level, as measured by plate counts and substrate degradation assays (starch, cellulose, and protein). The half-lives of C-14 fenvalerate in the 0.2- and 1.0 ppm noncolumn treatments were 6.3 and 8.9 days, respectively. The lower half-life (3.2 days) observed in the 1.0 ppm column treatment was attributed to a higher leaching rate in that treatment. TLC analysis of sediment extracts revealed the presence of three identifiable metabolites in all treatments after 4 days of incubation. (Baker-IVI)

ORIGINS OF SOME ARSENIFEROUS GROUNDWATERS IN NOVA SCOTIA AND NEW BRUNSWICK, CANADA,
National Hydrology Research Inst., Ottawa (Ontario).
D. J. Bottomley.
Journal of Hydrology, Vol. 69, No. 1-4, p 223-257, February, 1984. 16 Fig, 5 Tab, 70 Ref.

Descriptors: *Arsenic, *Groundwater, *Nova Scotia, *New Brunswick, Groundwater pollution, Mine wastes, Gold, Ferric oxyhydroxides, Hydrogeology, Chemical properties, Geochemistry.

The presence of arsenic in drinking-water supplies is a cause for concern since its potential toxicity, mutagenicity and carcinogenicity to man is still poorly understood and very controversial. Arsenic is relatively mobile under a broad range of pH-Eh conditions typical of groundwaters with the result that where arseniferous minerals are present in the subsurface, aresenic contamination of groundwaters has frequently be reported. Arsenic-contaminated groundwaters occur in regions of New Brunswick underlain by the Carboniferous volcanic tuff of the Harvey Formation, and in Nova Scotia where bedrock is comprised of early Paleozoic metasedimentary formations of the Meguma Group. At Harvey, N.B., aresenic is present in dispersed iron oxide aggregations in the tuff, whereas in the Meguma rocks arsenic is concentrated in arsenopyrite commonly present in quartz veins that were once mined for their gold content. The arsenic-contaminated groundwaters range in age from less than 10 yr. to greater than 100,000 yr. and are found both under oxidizing and reducing conditions. While the arsenic contamination in both areas is ultimately attributable to oxidation of arseniferous minerals, geochemical analyses of the aquifer materials in a former gold mining district of Nova Scotia suggest contamination of young groundwater may occur through exchange reactions with 'unsupported' extractable arsenic associated with ferric oxyhydroxides. The source of this extractable arsenic was likely infiltrated runoff that had been in contact with mine waste rock. (Murphy-IVI)

RESIDENCE TIME: APPLICATION TO SMALL BOAT BASINS,
Rosenstiel School of Marine and Atmospheric Science, Miami, FL.
J. van de Kreeke.
Journal of Waterway, Port, Coastal and Ocean Engineering, Vol. 109, No. 4, p 416-428, November, 1983. 4 Fig, 5 Ref.

Descriptors: *Residence time, *Boat basins, Water pollution, Marine environment, Recreation wastes, Boating, Marinas, Water circulation, Mathematical equations, Tidal hydraulics.

To assure that concentrations of pollutants remain below critical levels, the pollutant input has to be small and the rate at which the water in the boat basin is exchanged has to be large. Using a continuous exchange model, analytical expressions for the transit time distribution function and the age distribution function are derived for a basin having a constant volume. The residence time for instantaneous as well as continuous dye injections equals the volume of the basin divided by the rate at which new water is added to the basin. Using the tidal prism model it is shown that the normalized residence time for an instantaneous dye injection is a function of three dimensionless parameters. These parameters are: (1) The average basin volume divided by the volume of new water returning on the flood; (2) the fraction of the flood volume (= tidal prism) that is new water; and (3) the phase of the tide at which the dye is injected. For a continuous dye injection, the normalized residence time is a function of the first two parameters only. Numerical computations show that, to a first approximation, the residence times equal the average basin volume divided by the volume of new water entering during flood with secondary effects introduced by the other parameters. LANDFILL LEACHATE MIGRATION THROUGH SHALLOW UNCONFINED AQUIFERS,
Massachusetts Univ., Amherst. Dept. of Civil Engineering.
D. W. Ostendorf, R. R. Noss, and D. O. Lederer.
Water Resources Research, Vol. 20, No. 2, p 291-296, February, 1984. 1 Fig, 4 Tab, 22 Ref.

Descriptors: *Landfills, *Leachates, *Aquifers, Model studies, Transport, Groundwater pollution, Water pollution sources, Kinetics, Adsorption.

The transport of a simple reactive contaminant through a landfill and an initially pure, underlying shallow, one-dimensional unconfined aquifer has been modeled. The aquifer has a plane, sloping bottom with steady hydraulic conditions. Absence of dispersion and downgradient dilution were assumed. The user population and a presumedly constant contaminant loading factor determine the pollution input to the groundwater system. The near field response is modeled as a single linear reservoir whose output comprises the far field source term at the downgradient edge of the landfill. The far field analysis yields a method of characteristics solution valid in the vicinity of the source location with frame speeds modified by recharge, head loss, bottom slope, and linear adsorption, and concentrations reflecting first order reaction kinetics. The near and far field models are calibrated and tested against conservative chloride and first order reactive bicarbonate data at the Babylon, New York landfill with accurate and physically plausible results. SOLUTE REDISTRIBUTION DURING NORMAL FREEZING,
Iowa Univ., Iowa City.
W. K. S. Leung, and G. R. Carmichael.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 141-150, January, 1984. 8 Fig, 1 Tab, 6 Ref.

Descriptors: *Path of pollutants, *Model studies, *Freezing, *Solutes, Mathematical models, Burton-Slichter film theory, Films, Snowmelt, Ice.

In northern areas where snow precipitation is abundant in winter time, 50 to 80% of the pollutants accumulated in the snowpack are released when the first 30% melts. The very first meltwater may have concentrations 5 times the values found in the bulk. A thorough understanding of snow and ice pack chemistry and melting is necessary to predict the chemical composition and delivery rates of meltwater aquatic systems. An investigation of segregation of solutes and their transport properties in ice layers is reported and techniques for estimating solute redistribution resulting from normal freezing processes are presented. Mathematical models used in metallurgy to describe solute partitioning are applied to solute distribution in ice crystals. The method can be used to estimate distribution coefficients from experimental data. Under the assumptions of this model the solute concentration in the solid is linearly dependent on the solute concentration in the liquid and the distribution coefficient is concentration independent and constant. However, predicted distribution coefficients varied with the fraction frozen. The deviation of experimental results from normal freezing theory is consistent with the Burton-Slichter film theory model. (Baker-IVI)

SULPHATE AND NITRATE RELATED TO ACIDITY IN RAINWATER,
Central Energy Generating Board, Ratcliffe-on-Soar (England). Scientific Services Dept.
A. Martin.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 271-277, January, 1984.

Descriptors: *Acid rain, *Sulfates, *Nitrates, Water pollution sources, Monitoring, Acidity, Sampling, Europe, Hydrogen ion concentration.

Sulfate and nitrate concentrations in rainwater were shown to vary systematically with the acidi-

ties of the samples from certain rural sites from Europe and the U.S. Major differences were found between strong- and weakly-acid rainwaters. The mean non-sea sulfate to H(+) ratios in the weakest acid class correlate significantly with the annual SO2 in air for the 8 sites in Europe whereas those in the strongest acid class do not. The mean ratios of nitrate to H(+) show a similar pattern to the ratios of sulfate to H(+), but the weakly acid values are only about 0.33 as large. Weakly acid samples could modify on standing and therefore special care is needed in attempts to use them to identify sources. Some differences are noted between samples from Europe and from the Northeastern United States, possible due to the differences in the types of collectors used. In terms of possible effects, rainwater sampled by open collectors for the period over which effects may develop, and modifying as they will, might be an adequate simulation of rain on some types of surfaces. Only strong acid cloud and rainwaters, sampled as events (or daily) in ways that minimize changes in the solutions, are likely to be relevant to their initial composition. Weak acid samples, or mixtures of strong and weak acid samples, should only be used for that purpose with the utmost care. (Baker-IVI)

MOVEMENT OF PHORATE UNDER CONSTANT AND VARIABLE SURFACE WATER FLUX IN INITIALLY DRY AND MOIST SOILS,
Haryana Agricultural Univ., Hissar (India). Dept. of Entomology.
G. Singh, I. S. Dahiya, and Z. Singh.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 439-446, January, 1984. 4 Fig, 2 Tab, 16 Ref.

Descriptors: *Insecticides, *Leaching, Phorate, Organic compounds, Soil properties, Soil water, Surface water.

Agricultural chemicals applied to the soil surface are susceptible to transport through the soil profile with the flowing soil water when water infiltration occurs as a consequence of rainfall or irrigation. The distribution of phorate was studied in three texturally different soils under constant and variable surface flux of water. Phorate distribution profiles and leaching curves showed that the insecticide was displaced more efficiently and its concentration peak formed at deeper depth with constant than with variable water flux in sandy loam soils irrespective of initial soil water content. Phorate distribution profiles, however, were independent of the methods of water application in clay soil because of its extremely low permeability. Phorate distribution was considerably dependent on the initial soil water content. The greater the initial soil water content, the greater was the penetration of phorate. (Baker-IVI)

DISSOLVED NITROGEN SUPERSATURATION OF A HEATED EFFLUENT,
Delaware Univ., Newark. School of Life and Health Sciences.
D. A. Neumann, E. L. Melisky, and W. J. Wachter, Jr.
Water, Air, and Soil Pollution, Vol. 22, No. 1-4, p 1-13, January, 1984. 5 Fig, 3 Tab, 17 Ref.

Descriptors: *Dissolved nitrogen, *Supersaturation, *Heated water, *Effluents, Electric powerplants, Nitrogen, Water pollution effects, Cooling water, Water temperature, Thermal pollution, Fishkill, Erie, Pennsylvania.

Electric power generation constitutes one of the largest industrial uses of water in the United States. Presented is an empirical assessment of the dynamics of dissolved gas supersaturation in the effluent of a steam electric generating station in response to observations of mass mortalities among fish overwintering in a heated effluent. Surface water samples were collected from the intake, discharge, and heated plume of a fossil-fueled electric generating station from January 1974 through September 1976. Dissolved N2 concentrations were determined manometrically for each sample and the percent saturation of each was calculated. Intake N2 levels were near saturation throughout the sampling period while discharge N2 values consistently exceeded saturation, often ranging from 110% to 120% saturation. Saturation levels based on N2 analysis and on polarographic measurement O2 did not differ significantly. Discharge saturation levels were predictable from a three variable equation which considered the rise in cooling water temperature (delta T), percent N2 saturation at the intake, and cooling water flow rate. Other parameters associated with cooling system operation were not significantly related to the discharge N2 level. First-order regression analysis indicated that discharge saturation levels could be readily estimated from delta T measurements. Seasonal variation in supersaturation levels at the discharge was related to the interaction of the delta T and the intake temperature. Supersaturation occurred throughout the heated effluent; levels decreased with increasing distance from the discharge. Dissipation of supersaturated conditions in the plume resulted from cooling and was predictable. (Murphy-IVI)

BULK DEPOSITION OF METALS IN TULSA, OKLAHOMA,
Oklahoma State Univ., Stillwater. Dept. of Civil Engineering.
M. B. Tata, and M. H. Bates.
Water, Air, and Soil Pollution, Vol. 22, No. 1, p 15-26, January, 1984. 6 Fig, 3 Tab, 27 Ref.

Descriptors: *Metals, *Deposition, *Arkansas River, *Tulsa, *Oklahoma, *Precipitation, Cadmium, Chromium, Lead, Nickel, Zinc, Heavy metals, Water pollution sources.

A low water dam is being constructed on the Arkansas river near downtown Tulsa, Oklahoma and it is feared that the quiescent pool which will be formed could be a sink for toxic heavy metals. Samples of bulk precipitation (wet and dry fallout) were collected at six sites adjacent to the Arkansas River in Tulsa over an 11 month period and analyzed by flameless atomic absorbtion spectrophotometry for cadmium, nickel, chromium, lead, and zinc. Metal deposition was fairly constant from site to site and appeared to be proportional to the amount of precipitation collected. Zinc was by far the largest contributing metal at 497 mg/sq m/yr, followed by Pb, Cr, Ni and Cd at 25.5, 25.7, 7.02, and 0.95 mg/sq m/yr, respectively. Concentration data vaired greatly over the collection period. The average volume-weighted concentrations in micrograms per liter were CD-2.1, Cr-57.0, Ni-15.6, Pb-56.6, and Zn-1100. (Baker-IVI)

BENZ(A)PYRENE INPUT AND OCCURRENCE IN A MARINE AREA AFFECTED BY REFINERY EFFLUENT,
Marine Pollution Lab., Charlottenlund (Denmark).
K. Jensen.
Water, Air, and Soil Pollution, Vol. 22, No. 1, January, 1984. 3 Fig, 5 Tab, 10 Ref.

Descriptors: *Organic compounds, *Benz(a)pyrene, *Kalundborg Fjord, *Denmark, Oil wastes, Industrial wastes, Water pollution sources, Sediments, Degradation, Advection, Fate of pollutants.

The load of benz(a)pyrene (BaP) in Kalundborg Fjord, a marine coastal area in the vicinity of a town and an oil refinery was estimated. An oil refinery discharges 1,500,000 cu m/yr of wastewater into the inlet. The levels of the compound in refinery effluent, municipal wastewater, urban run-off, rivers, and atmospheric fall-out have been determined. Three major routes are assumed to account for the removal of BaP from the water body of Kalundborg Fjord. These include degeneration in the water, sedimentation and advective water exchange. The major problem to estimating the removal of BaP from the water body is to estimate the standing stock of BaP. The degradation rate is very slow. At one station in the fjord the sedimentation rate of dry matter has been determined at 740 g/sq m/yr. If the BaP content of the sedimentated materials equals the level in the surface sediment at this particular station, 41 micro g/kg, the sedimentation would be 30.3 micro g/sq m/yr. The remaining part of BaP, approximately 1 kg, is removed by advective water transport. (Baker-IVI)

BACTERIAL POLLUTION OF GROUNDWATER: A REVIEW,
Oregon State Univ., Corvallis. Dept. of Agricultural Engineering.
S. R. Crane, and J. A. Moore.
Water, Air, and Soil Pollution, Vol. 22, No. 1, p 67-83, January, 1984. 2 Fig, 4 Tab, 83 Ref.

Descriptors: *Bacteria, *Groundwater pollution, Wastewater Disposal, Wastewater pollution, Reviews, Soil contamination, Soil classification, Soil physical properties, Soil water, Wastewater management, Infiltration.

Contamination of groundwater resources from bacterial laden wastewater and effluents poses a great threat to potability and use of these water sources. Future planning, development and management schemes must consider this topic to avoid costly and sometimes untested corrective actions. Major factors affecting the quantity and velocity at which bacteria are able to migrate through soil can be classified as (1) soil factors including particle size distribution, structure, clay content, pore size distribution and moisture regime, and (2) biological factors responsible for bacterial die-off including pH, temperature, moisture content, and nutrient supply. Past bacterial pollution problems have been shown to be localized and restricted to wells utilizing near-surface waters. The following problem areas exist and must be given special consideration in planning and development: (1) use of septic disposal systems in unsuitable soils; (2) drainage water from wastewater application areas utilizing artificial drainage systems; (3) waste application in areas underlain by fractured crystalline rock or channelized bedrock; and (4) bacterial contamination induced over great distances by groundwater pumping. WATER QUALITY AT AND ADJACENT TO THE SOUTH DADE COUNTY SOLID-WASTE DISPOSAL FACILITY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
D. J. McKenzie.
Available from the Ofss, USGS, Lakewood, CO 80225; Price: $5.25 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 83-4003, 1983. 37 p, 8 Fig, 8 Tab, 23 Ref.

Descriptors: *Water quality, Landfill, Leachate, *Limestone aquifer, Organic decomposition, Solid waste, *Biscayne aquifer, Biscayne Bay, *Florida, *Nitrification, Chloride indicator, Ammonia tracer, Ammonia migration, Alkalinity.

A water-quality reconnaissance was conducted at the south Dade County solid-waste landfill near Goulds, Florida, from December 1977 through August 1978. The landfill is located directly on the unconfined Biscayne aquifer, which, in the study area, is affected by saltwater intrusion. Water samples collected from six monitor well sites at two depths and four surface-water sites were analyzed to determine the chemical, physical, and biological conditions of the ground water and surface water of the study area. Results indicated that water quality beneath the landfill was highly variable with location and depth. Leachate was generally more evident in the shallow wells and during the dry-season sampling, but was greatly diluted and dispersed in the deep wells and during the wet season. High concentrations of contaminants were generated primarily in areas of the landfill with the most recent waste deposits. Chloride (limited to the shallow wells and the dry season), alkalinity, ammonia, iron, manganese, lead, phosphorus, and organic nitrogen indicate leachate contamination of the aquifer. Water-quality characteristics in the

surface waters were generally only slightly above background levels. (USGS)

HYDROLOGIC INFORMATION FOR LAND-USE PLANNING, BADGER ROAD AREA, FAIRBANKS, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
A. P. Krumhardt.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $2.25 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigations Report 82-4087, 1982. 14 p, 5 Fig, 3 Tab, 8 Ref.

Descriptors: Public health, Arsenic, Nitrate, Iron, Hardness, Water table, Groundwater movement, Water-level fluctuations, Fairbanks, *Alaska, Groundwater, Water wells, Water quality, Water levels.

The relatively flat Badger Road area near Fairbanks occupies part of the alluvial plain of the Chena and Tanana Rivers and is underlain by scattered areas of permafrost. The water table of the high-transmissivity aquifer that underlies the area is generally shallower than 15 feet, fluctuates seasonally about 2 feet, and slopes northwesterly, the direction of ground-water flow. Private domestic-supply wells obtain water from the upper part of the aquifer. Septic systems used to dispose of waste water are installed at or only slightly above the water table in the same aquifer. Analyses of samples from 16 observation wells in undeveloped parts of the study area and from 33 domestic wells indicated that water quality has not been significantly degraded by on-site waste disposal. Three samples had detectable but minor contamination by fecal coliform bacteria. Anomalous values of chloride and ammonia in one third of the domestic wells may indicate incipient degradation of ground-water quality by septic-tank effluent. (USGS)

Available from the Ofss, USGS, Lakewood, CO 80225, Price: $16.50 in paper copy, $4.00 in microfiche. USGS Water-Resources Investigations Report 82-4002, 1983. 93 p, 44 Fig, 4 Tab, 22 Ref.

Descriptors: *Hydrogeology, *Glacial drift, *Groundwater, Aquifers, Water supply, Groundwater movement, Water pollution, *Path of pollutants, Organic compounds, Wurtsmith Air Force Base, Iosco County, *Michigan.

A sand and gravel aquifer about 65 feet thick underlies Wurtsmith Air Force Base in northeastern lower Michigan. The water table ranges in depth from 10 feet to 25 feet below land surface. Mathematical models indicate that ground-water flow ranges from 0.8 feet per day in the eastern part of the Base to 0.3 feet per day in the western part. Trichlorethylene leaked from a buried storage tank in the southeastern part of the Base and moved northeastward in a plume, contaminating Base water-supply wells. Concentrations exceed 1,000 micrograms per liter in the most highly contaminated part of the plume. Purge pumping removed some of the trichloroethylene and seems to have arrested its eastward movement. Pumping of additional purge wells could increase the rate of removal. (USGS)

POLLUTION STUDIES ON NIGERIAN RIVERS: THE ONSET OF LEAD POLLUTION OF SURFACE WATERS IN IBADAN,
Ibadan Univ. (Nigeria). Dept. of Chemistry.
C. Mombeshora, O. Osibanjo, and S. O. Ajayi.
Environment International, Vol. 9, No. 2, p 81-84, 1983. 4 Tab, 7 Ref.

Descriptors: *Nigeria, *Ibadan, *Lead, Water pollution, Agodi Lake, Oba Lake, Ogunpa Stream, Ona River, Lake of the International Institute of Tropical Agriculture, Traffic density.

Lead levels in the waters and sediments of the lake of the International Institute of Tropical Agriculture, Agodi Lake, Oba Lake, at three stations on Ogunpa stream, and at three stations on Ona River were measured from October 1977 to June 1978, using the combined APDC-MIBK-flame atomic absorption spectrophotometry technique. The lead levels recorded ranged from 0.2 to 46 microg/L for the aqueous phases; however, the levels in the sediments were much higher, ranging from about 18 to 85 mg/kg (dry weights). Although there is nothing alarming about these levels, the levels of lead in water bodies located in areas with high traffic density were consistently higher than levels for comparable waters in low traffic density areas. Similarly, lead levels were significantly higher in the fresh sediments of water bodies in areas with high traffic density, clearly indicating the onset of lead pollution for those high traffic density areas. OIL POLLUTION STUDIES IN THE NILE RIVER. 1. SURVEY OF OIL AND GREASE IN NILE WATER,
National Research Centre, Cairo (Egypt). Water Pollution Control Lab.
A. S. Moursy.
Environment International, Vol. 9, No. 2, p 107-111, 1983. 1 Fig, 4 Tab, 14 Ref.

Descriptors: *Oil pollution, *Ships, *Nile River, *Egypt, Seasonal variations, Vaporization, Water quality control, Water analysis, Powerplants, Lake Nasser, Harbors.

A survey of oil and grease along the Nile River indicated the presence of variable concentrations of these pollutants. Five segments were identified along the Nile River: the Aswan, Assiut, Cairo, Demietta and Rossetta segments. Some stations along the Nile are more polluted than others. These are located mostly at Lake Nasser Port (Aswan segment); oil distribution centers and ship waiting areas (Assiut segment); boat docks, a ship yard, and an electric power station (Cairo segment); and at factory areas (Rossetta segment). The level of oil and grease decreased significantly when moving downstream. The dilution effects result in a lower level of the pollutants in these waters. Furthermore, various chemical, physical, and biological processes that are known to degrade or destroy oil in water undoubtedly contributed to the general decrease in the pollutant concentrations observed. The level of oil and grease along the river was also lower in summer than in winter and spring which may be attributed to the decrease of activities and increase of vaporization processes. ASSESSMENT OF EL-SALAAM UNDERGROUND WATER FOR POULTRY USE,
National Research Centre, Cairo (Egypt). Water Pollution Control Lab.
H. T. El-Zanfaly, M. R. Lasheen, M. M. El-Abagy, S. A. El-Hawaary, and M. I. Badawy.
Environment International, Vol. 9, No. 4, p 313-317, 1983. 1 Fig, 2 Tab, 23 Ref.

Descriptors: *Water quality, *Bacteria, *Groundwater, *Egypt, El-Salaam, Wells, Water pollution sources, Fecal coliforms, Acidity, Sulfates, Alkalinity, Coliforms, Pesticides.

Water quality was investigated in 13 wells in El-Salaam, near Cairo. The wells were dug specifically to provide water for a company specializing in broiler poultry production. The water was analyzed for the following bacteriological parameters: total bacterial counts, total coliforms, fecal coliforms, fecal streptococci, aerobic spore formers, and total counts for Clostridium per 100 mL. Chemical parameters such as pH, sulfate, alkalinity, hardness, and pesticides indicate that the water is unacceptable for poultry production. Bacteriological testing revealed the same conclusion. Wastewater in an open drain is entering the groundwater. This wastewater contains tremendous concentrations of untreated discharges and represents a significant source of water pollution. (Baker-IVI)

INTERACTIONS BETWEEN DISSOLVED AND SOLID METAL SPECIES IN INLAND WATERS (WECHSELWIRKUNGEN ZWISCHEN GELOSTEN UND FESTEN METALLSPEZIES IN BINNENGEWASSERN),
Technische Univ., Hamburg (Germany, F.R.). Arbeitsbereich Umweltschutztechnik.
U. Forstner.
Fresenius Zeitschrift fur Analytische Chemie, No. 3-4, p 359-360, 1984. 20 Ref.

Descriptors: *Heavy metals, *Inland waters, Hydrologic properties, Chemical properties, Hydrologic cycle, Sediments, Particle size.

Intense industrialization in the Federal Republic of Germany has led to high concentrations of metals. In particular toxic levels of Hg is of high concern. Heavy metal interactions don't always form agglomerations in water but in the case where there is intense quantities of heavy metals a situation can occur where these metals coalesce. Heavy metal sorption reactions on mineral substrates like FeOOH, SiO2 or Al2O3 have sorption in water with 1-1.5 pH from 0 to 100%. The combination of heavy metals and extensive high pH in fresh water increases the potential for agglomeration of the heavy metals with sediment load. Particle size also dictates the potential for mineralization. (Murphy-IVI)

W. Spickermann, and G. Stork.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 317, No. 3-4, p 361-365, 1984. 2 Fig, 3 Tab, 6 Ref.

Descriptors: *Sediments, *Mercury, Factor analysis, Ion exchange, Lahn River, Marburg, Federal Republic of Germany, Organic compounds.

A study was made on the mercury contents of sediments from the river Lahn and three tributary rivers in the area of Marburg. The contents of carbon and the weight percentage of the grain size fraction < 63 microm were determined. The degrees of contamination were compared and the effect of the input of a purification plant was examined. The sediments of the Lahn, which do not belong to the direct area of influence of a purification plant, as well as the sediments of the three tributary rivers are only weakly contaminated. Factor analysis was applied to achieve a data reduction. It suggests that the bonding of mercury to the sediments is caused mainly by organic substances. Adsorption or ion-exchange are of minor importance. (Murphy-IVI)

SURFACE RUNOFF WATER QUALITY COMPARISONS BETWEEN UNIMPROVED PASTURE AND WOODLAND,

Science and Education Administration, Coshocton, OH. North Appalachian Experimental Watershed.
L. B. Owens, W. M. Edwards, and R. W. Van Keuren.

Journal of Environmental Quality, Vol. 12, No. 4, p 518-522, 1983. 2 Fig, 5 Tab, 23 Ref. EPA grant R-804631.

Descriptors: *Surface runoff, *Water quality, Comparison studies, Pastures, Woodlands, Chemical properties, Sediment transport, Organic compounds, Input-output analysis.

The influence of pasturing on surface runoff water quality was studied on a 26-ha, unimproved pasture watershed in eastcentral Ohio. Data were collected for 2 y with no cattle in the pasture and for 3 y with summer grazing by a 17-cow beef cattle herd. Because of springs and seep areas in the pasture, a small stream (accessible to the cattle) in the watershed flowed permanently. Samples of storm runoff were collected with a rotating vane sampler. The concentrations of most of the measured chemical parameters (NO3-N, mineral N, organic N, total P, K, Ca, Mg, Na, S, Cl, HCO3, total organic C, salts) in the storm discharge water were low and changed very little as a result of grazing. The weighted annual NO3-N concentrations for the ungrazed period and grazed period were 0.5 and 0.7 mg/L, respectively. A 17.7-ha, wooded watershed that contained no pastured areas and received no agricultural chemical limits, had concentrations of chemical parameters in surface discharge that were greater than or equal to those from the unimproved pasture during the grazing period. Nutrient transport during storm runoff from the unimproved pasture was greater during the 3-y period with summer grazing than during the 2-y, ungrazed period. This largely resulted from increased precipitation and subsequent increased surface runoff during the 3-y period. The transport levels from the pasture during the 3-y period were similar to or less than the transport levels from the wooded watershed during the same period. The increase in sediment transport from the pastured areas was more than could be attributed solely to the increased surface runoff. (Author's abstract)

AZINPHOSMETHYL AND FENVALERATE RUNOFF LOSS FROM A SUGARCANE-INSECT IPM SYSTEM,

Louisiana Agricultural Experiment Station, Baton Rouge.
S. Smith, T. E. Reagan, J. L. Flynn, and G. H. Willis.

Journal of Environmental Quality, Vol. 12, No. 4, p 534-537, 1983. 2 Tab, 19 Ref.

Descriptors: *Azinphosmethyl, *Fenvalerate, *Runoff loss, Runoff volume, Sugarcane, Insecticides, Aquatic habitats, Ecological effects.

Agriculture in the lower Mississippi River Valley greatly depends on the use of pesticides to help control severe weed and insect pest infestations and increase crop yields. Azinphosmethyl and fenvalerate were applied to sugarcane (Saccharum officinarum L.) runoff plots at rates of 0.84 and 0.22 kg/ha, respectively, 4 times each year in 1980 and 1981 as part of an insect integrated pest management (IPM) system research evaluation for season-long control of the primary sugar-cane insect pest, the sugarcane borer. Runoff samples (water + sediment) were collected within 8 ha after each storm and analyzed by gas chromatography. In 1980, runoff losses of azinphosmethyl and fenvalerate were 0.08 and 0.02%, respectively, of the amount applied. Runoff in 1981 was about twice that in 1980, partially accounting for larger insecticide runoff losses measured, 0.55 and 0.56% of that applied for azinphosmethyl and fenvalerate, respectively. The larger 1981 losses also were attributed to shorter time intervals between insecticide applications and runoff events. Azinphosmethyl concentrations in runoff do not appear to be harmful to surrounding aquatic habitats, whereas fenvalerate concentrations might present problems, particularly if applied at 0.22 kg/ha rates. NUTRIENT CYCLING IN AN AGRICULTURAL WATERSHED: I. PHREATIC MOVEMENT,

Agricultural Research Service, Tifton, GA. Southeast Watershed Research Center.
R. R. Lowrance, R. L. Todd, and L. E. Asmussen.

Journal of Environmental Quality, Vol. 13, No. 1, p 22-27, 1984. 3 Fig, 3 Tab, 18 Ref. NSF grants DEB 78-10841 and DEB 82-07210.

Descriptors: *Cycling nutrients, *Agricultural watershed, *Groundwater movement, Runoff, Subsurface runoff, Riparian ecosystem, Riparian vegetation, Nitrate, Phosphorus, Calcium, Magnesium, Potasium, Chloride, Sulfate, Sinks, Nutrient removal, Biological filters.

Much of the runoff from agricultural fields in the southeastern Coastal Plain is carried to a stream channel system in a shallow phreatic aquifer. This subsurface runoff often passes through a band of riparian forest before becoming streamflow. It is hypothesized that the riparian ecosystem acts as a nutrient sink and reduces the concentrations and loads of nutrients in the shallow aquifer before the nutrients reach the stream channel. Concentrations and loads (kg/sq m) of NO3-N, NH4-N, organic N, dissolved molydate-reactive P, total P, Ca, Mg, K, Cl, and SO4-S were measured in shallow phreatic wells at 37 locations on an agricultural watershed near Tifton, Ga. Total water volume moving off the watershed in subsurface flow was < 1% of streamflow with corresponding small amounts of nutrients. Nitrate-N, Ca, and Mg had significantly higher concentrations in field wells than in forest or streamside wells. Concentrations of Cl were not reduced as water moved from field to forest. Processes within the riparian zone apparently converted primarily inorganic N from fields (76% NO3-N, 6% NH4-N, 18% organic N) into primarily organic N in streamside wells (10% NO3-N, 14% NH4-N, and 76% organic N). Concentration differences between field and forest wells indicated the riparian forest's ability to act as a sink for NO3-N, Ca, Mg, K, and SO4-S. Due to their role as nutrient sinks, riparian forests are important in maintaining stream water quality on agricultural watersheds. (Author's abstract)

ATMOSPHERIC DEPOSITION AND ROOF-CATCHMENT CISTERN WATER QUALITY,

Pennsylvania State Univ., University Park. School of Forest Resources.
E. S. Young, Jr., and W. E. Sharpe.

Journal of Environmental Quality, Vol. 13, No. 1, p 38-43, 1984. 1 Fig, 4 Tab, 16 Ref.

Descriptors: *Roof-catchment cistern, *Water quality, Air pollution, Water pollution sources, Acid rain, Heavy metals, Water quality standards, Lead, Copper, Cadmium, Toxic metals, Clarion county, Indiana county, Pennsylvania.

Roof-catchment cistern systems consist mainly of a roof that functions as an impervious catchment for collecting precipitation and a storage tank, or cistern. The water is pumped from the cistern through a system of pipes to points of use within the house. The water quality in 40 roof-catchment cistern systems in rural Clarion and Indiana Counties, Pa. was studied to determine the impact of atmospheric deposition. Roof-catchment cisterns are open to atmospheric contaminants such as the toxic metals Pb and Cd, and corrosive acid components present in acid precipitation. Bulk precipitation samples failed to meet the drinking water standard for Pb on several occasions and were consistently quite corrosive. Mean Pb, Cd, and Cu concentrations were well below drinking water limits for all cistern water samples. Cistern water was corrosive in all but a few cases, as indicated by the Langelier saturation index, although not as corrosive as the bulk precipitation due to the dissolution of CaCO, from cistern walls and floors. Vinyl-lined cisterns contained water nearly as corrosive as the incoming precipitation. Seventy percent of the systems on one or more occasions exhibited cistern bottom sediment/water Pb or Cd concentrations that exceeded the drinking water limits. This indicated that metals deposited on roof catchments were accumulating at the bottom of the cisterns. Standing tap water samples exhibited high Pb and Cu concentrations. Nine of the forty systems studied produced standing tap water Pb concentrations that averaged above the drinking water standard. The mean Pb, Cd, and Cu concentrations of running tap water samples all fell below the drinking water standards. Atmospheric deposition of Pb and its infusion into tap water as a corrosion product pose a significant health threat to users of roof-catchment cistern systems in western Pennsylvania. (Murphy-IVI)

DISSIPATION OF PICLORAM IN STORM RUNOFF,

Agricultural Research Service, Temple, TX.
H. S. Mayeux, Jr., C. W. Richardson, R. W. Bovey, E. Burnett, and M. G. Merkle.

Journal of Environmental Quality, Vol. 13, No. 1, p 44-49, 1984. 5 Fig, 3 Tab, 19 Ref.

Descriptors: *Picloram, *Storm runoff, Nonpoint pollution sources, Herbicides, Watersheds, Riesel, Texas.

Picloram is currently used to control woody plants and herbacious weeds on rangelands. Its effectiveness is partially attributed to its greater persistence, compared with other herbicides, a characteristic which limits its use on cropped land. The extent of progressive decrease in concentration of the herbicide picloram (4-amino-3,5,6-trichloropicolinic acid) in intermittent streamflow was determined during runoff-producing storms. Maximum concentrations of picloram were 48 and 250 mg/cu m in initial runoff water leaving a sprayed 8-ha area in 1978 and 1979. Concentration decreased with distance from the treated area in proportion to the size of adjacent, untreated watershed subunits, which contributed runoff water to streamflow. Picloram concentrations usually decreased with each successive runoff event; an exception occurred when unusually large quantities of runoff (8.7 cm) diluted concentrations to levels less than those observed in the succeeding event (1.4 cm runoff). About 6% of the applied picloram left the treated area during a period of 1 month when conditions were especially conducive to transport of the herbicide in surface runoff water. Rapid dilution of picloram was observed after direct introduction of the herbicide near the upper end of a larger stream during rising stage of flow. Maximum concentrations at 90, 1170, and 5400 m downstream from the point of introduction of 1270 g of picloram were 13 720, 470, and 5 mg/cu m, respectively. The calculated quantity of picloram which was detected at the 5400-m sampling point in streamflow was only 0.13% of that introduced. Mixing of water during streamflow and additions of uncontaminated water along the channel apparently reduced picloram concentration to below that detectable by gas chromatography. (Murphy-IVI)
W84-03937

ALGAL AVAILABILITY OF PHOSPHORUS IN SUSPENDED STREAM SEDIMENTS OF VARYING PARTICLE SIZE,

Purdue Univ., Lafayette, IN. Dept. of Agronomy.
R. A. Dorich, D. W. Nelson, and L. E. Sommers.

Journal of Environmental Quality, Vol. 13, No. 1, p 82-86, 1984. 4 Tab, 23 Ref. EPA grant G00533501.

Descriptors: *Algae, *Phosphorus, *Streams, *Suspended sediments, *Particle size, Agricultural watersheds, Inorganic phosphorus, Eutrophication, Bioassay, Algal growth.

Phosphorus limits algal growth in many aquatic systems and inputs of P into such systems have caused algal blooms and associated water quality problems. The availability of sediment P to algae was evaluated in several water stable aggregate-size fractions of suspended stream sediments collected from an agricultural watershed in northeastern Indiana. Sediments were collected during a

storm event, separated into the < 2, 2 to 20, 20 to 53, 53 to 212, and > 212 microm size fractions, sterilized by gamma irradiation, and incubated for 2 weeks with algae. Algal-available P (Paa) was determined by measuring decreases in the NaOH- and HCl-extractable inorganic P (Pi) fractions in sediment during the incubation period. The initial concentrations of P in the NaOH- and HCl-extractable Pi fractions were not related to aggregate size. All aggregate-size fractions had similar Paa concentrations. Nearly equal proportions of sediment Pi (avg 79%) and total P (avg 43%) in aggregate fractions were available to algae, possibly resulting from the similar distribution of primary particle sizes in all aggregate-size fractions. More than 93% of Paa originated in the NaOH-extractable P fraction. Samples that were affected by septic effluents tended to be higher in certain sediment P parameters (e.g., NaOH-extractable Pi, total Pi, total P, and Paa concentrations) than samples containing suspended sediment derived from cropland. This study suggests that runoff models may not need to account for the detachment and transport of aggregate-size classes to predict the movement of algal-available P from cropland to surface waters. FACTORS AFFECTING PHOSPHORUS LOSSES FROM CULTIVATED ORGANIC SOILS,
North Carolina State Univ. at Raleigh.
C. Cogger, and J. M. Duxbury.
Journal of Environmental Quality, Vol. 13, No. 1, p 111-114, 1984. 4 Fig, 4 Tab, 22 Ref.

Descriptors: *Phosphorus, *Soil organic matter, Leaching, Water quality, Soil horizons, Aluminum, Iron, Fertilization, Nonpoint pollution sources, Phosphorus absorption, Fertilization, Histosols, New York.

Organic soils play an important role in agricultural production, but their potential as nonpoint sources of pollution through nutrient leaching is also important. Leaching losses of P from organic soils can have a marked effect on water quality. Factors affecting leaching loss of P from cultivated organic soils in western New York State (Carlisle and Palms series) and ways to reduce these losses were investigated. The behavior of P in organic soils from eight sites with annual leaching losses ranging from < 1 to > 30 kg/ha/y was compared. Inorganic, organic, and total P; P extracted by soil test procedures; percent mineral matter; depth of organic horizons; leaching and adsorption of P; release of P during incubation; and total extractable Al and Fe were compared. Phosphorus balance was estimated using field and laboratory data, and cropping and fertilization history. Aluminum, iron and adsorption equilibria were the best predictors of field leaching losses from these soils. While P loss from these soils is controlled by adsorption reactions, the best way to reduce the loss is through fertilizer management. (Murphy-IVI)

ATRAZINE AND SIMAZINE MOVEMENT TO WYE RIVER ESTUARY,
Agricultural Research Service, Beltsville, MD. Soil Nitrogen and Environmental Chemistry Lab.
D. E. Glotfelty, A. W. Taylor, A. R. Isensee, J. Jersey, and S. Glenn.
Journal of Environmental Quality, Vol. 13, No. 1, p 115-121, 1984. 5 Fig, 3 Tab, 29 Ref.

Descriptors: *Atrazine, *Simazine, *Wye River, *Estuaries, Runoff, Agricultural runoff, Agricultural watersheds, Herbicides, Water pollution sources, Fate of pollutants, Chesapeake Bay.

The Wye River, a tributary of Chesapeake Bay, is a shallow, well-mixed estuary surrounded by an agricultural watershed, a large portion of which is planted in corn (Zea mays L.). A 3-y study of the movement of atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine) and simazine (2-chloro-4,6-bis (ethylamino)-s-triazine) showed that the total amount of herbicide reaching the estuary depended upon the quality applied in the watershed and the timing of runoff with respect to application dates. In a year in which significant runoff occurred within 2 weeks of application, 2 to 3% of the atrazine moved to the estuary. In other years with less runoff, or runoff delayed longer after application, much smaller quantities reached the estuary. Simazine loading was one-tenth that of atrazine. Once in the estuary, atrazine and simazine remained in solution, diluted in a conservative manner with estuarine water, and dissipated with a 10- to 30- d half-life. The maximum measured concentration of atrazine was near 15 microg/L but average concentration at peak loading was < 3 microg/L. Thus, although the Wye River has a high percentage of watershed land planted to corn, herbicide concentrations rarely approached those producing minor effects on submerged aquatic vegetation. PASTURE RUNOFF WATER QUALITY FROM APPLICATION OF INORGANIC AND ORGANIC NITROGEN SOURCES,
Clemson Univ., SC. Dept. of Agricultural Engineering.
R. V. McLeod, and R. O. Hegg.
Journal of Environmental Quality, Vol. 13, No. 1, p 122-126, 1984. 7 Fig, 4 Tab, 12 Ref.

Descriptors: *Agricultural runoff, *Water quality, *Nitrogen, Nitrogen compounds, Water pollution sources, Fertilization, Waste disposal, Municipal wastewater, Manure, Water pollution, Fertilizer, Ammonium nitrate.

After an organic waste has been applied to a soil, some of the waste may be transported by rainfall runoff, snowmelt, or irrigation runoff into surface waters. Surface runoff water quality from a fescue pasture receiving surface application of organic wastes and commercial fertilizer was evaluated at Clemson University (Clemson, S.C.). Dairy manure, poultry manure, and municipal sludge were the organic wastes used in this experiment. Ammonium nitrate was the commercial fertilizer. The organic wastes and commercial fertilizer were applied at the rate of 112 kg N/ha to eight plots during four different periods. Due to an extremely dry year, runoff events were produced by irrigation. The runoff water was collected and samples were analyzed for pH, total P, total suspended solids, total Kjeldahl N, NH4-N, NO3-N, and chemical oxygen demand. The nutrient concentrations in surface runoff were more dependent on the number of rainfalls since application of the fertilizer than on the quantity of rainfall or runoff. The concentrations of potential pollutants from surface-applied organic wastes or commercial fertilizer were reduced by between 80 and 55% after two runoff events. The NO3-N concentration in the surface runoff from the plots receiving the commercial fertilizer exceeded the permissible public water supply standard during the first runoff event. The overall nutrient loss in the runoff was found to be minimal (< 4% of total Kjeldahl N and chemical oxygen demand and < 2.5% of total P). (Murphy-IVI)

BRYOZOANS-POSSIBLE INDICATORS OF ENVIRONMENTAL QUALITY IN BEAR CREEK, MISSISSIPPI,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
C. M. Cooper, and J. W. Burris.
Journal of Environmental Quality, Vol. 13, No. 1, p 127-130, 1984. 1 Fig, 1 Tab, 13 Ref.

Descriptors: *Bryozoans, *Bioindicators, *Bear Creek, *Mississippi, Aquatic ecosystem, Agricultural watersheds, Water quality, Suspended sediments, Sedimentation rates, Habitat, Water pollution effects, Hydrogen ion concentration.

Bryozoans do not indicate pollution by their presence, but some species have been considered pollution indicators by their absence. Collections of samples of water and substrate materials from lakes and stream sections of Bear Creek, Miss., were studied to determine the species of Bryozoa present in different habitats of an aquatic ecosystem with an intensively cultivated flatland watershed (440 km2). Bear Creek (83 km long), a tributary of the Yazoo River in the Mississippi River alluvial delta, is actually a series of six riverine lakes connected by a sluggishly flowing stream. The watershed also includes several other oxbow lakes connected to the stream only during periods of high discharge. Water quality as characterized by total and suspended sediments, deposited sediments, pH, and coliforms deteriorated in a downstream direction. Four species of the sessile colonial invertebrate were indigenous to the three lakes in the system having the lowest total solids, sedimentation rates, and pH. These included Plumatella fruticosa (Allman), Lophopus crystallinus (Pallas), Fredericella sultana (Blumenbach), and Pectinatella magnifica (Leidy). Absence of bryozoans, especially environmentally sensitive Pectinatella magnifica, in downstream areas correlated with degradation of downstream habitat and increased total solids. Selective habitation of these invertebrates in the Bear Creek stream system indicates the possible use of these organisms as environmental indicators of habitat quality. (Murphy-IVI)

DISSOLVED MINERAL SALTS DERIVED FROM MANCOS SHALE,
Kentucky Agricultural Experiment Station, Lexington. Dept. of Agronomy.
V. P. Evangelou, L. D. Whittig, and K. K. Tanji.
Journal of Environmental Quality, Vol. 13, No. 1, p 146-150, 1984. 1 Fig, 4 Tab, 9 Ref. OWRT project B-201-CAL, WRC project UCAL-WRC-W-582; OWRT grant P.L. 95-467.

Descriptors: *Mancos Shale, *Salinity, Gypsum, Alkaline earth carbonates, Mica, Kaolin, Smectite, Mica-vermiculite, Water pollution sources, Fate of pollutants, Cation exchange, Colorado River basin.

The Mancos shale, a sedimentary Upper Cretaceous marine formation exposed over extensive areas in the Upper Colorado River Basin, is recognized as a major contributor to the dissolved mineral salt load in the Colorado River system. It contains gypsum and alkaline earth carbonates, and its clay mineralogy is mica, kaolin, smectite, and interstratified mica-vermiculite. Selected surface samples of partially weathered Mancos shale were also found to contain from 281 to 345 g/kg clay (< 2 microm diam) and to exhibit cation exchange capacities (CEC) ranging from 13.25 to 19.96 cmol/kg. Water suspension extracts from partially weathered shale (1:5 and 1:10 shale/water ratios) were saturated with respect to gypsum (electrical conductivity (EC) values up to 3.16 dS/m and soluble Ca and SO4 up to 25.90 and 40.95 mmol/+ or - L, respectively). Additional Na, K, and Mg released by water indicated sources of soluble ions other than gypsum. Water extracts from unweathered shale yielded much higher quantities of Na (and higher Mg in most cases) than did comparable extracts from partially weathered shale. Barium chloride released larger quantities of Mg from both partially weathered and unweathered shale and large quantities of Na from unweathered shale than did water at comparable dilutions. The data substantiate the important role of the cation exchange complex in retention and release of soluble ions in Mancos shale. Sodium and magnesium were preferentially adsorbed by phyllosilicates within the shale and Ca was precipitated as calcite and gypsum following emergence after deposition in the Cretaceous sea. This cycle is essentially reversed in the present environment. Dispersed gypsum and alkaline earth carbonates provide soluble Ca to displace adsorbed Na and Mg that add to the dissolved mineral salt load of the Colorado River system. (Author's abstract)

Journal of Environmental Quality, Vol. 13, No. 1, p 156-161, 1984. 5 Fig, 2 Tab, 9 Ref.

Descriptors: *Shallow groundwater, *Water quality, *Multiple-cropping, Center pivot irrigation, Nitrogen compounds, Irrigation design, Irrigation effects, Groundwater pollution, Groundwater level, Soil horizons, Nitrate, Nitrogen, Leaching, Sandy soils, Coastal plain, Sprinkler irrigation, Fertilization, Groundwater flow.

Substantial increases in groundwater NO3-N are of particular concern on intensively cropped irrigated sandy soils. A study was conducted to compare shallow groundwater NO3-N concentrations under intensive multiple cropping systems with those from under nearby nonagricultural sites. The intensive multiple cropping systems involved center pivot irrigation and sprinkler-applied fertilizer. The study was conducted on a sandy Coastal Plain soil by weekly measurement and sampling of observation wells located under a center pivot area and at two forest sites. Nitrate-N concentrations under the center pivot area ranged from < 1 mg/L to about 133 mg/L, with a mean of 20 mg/L (n = 360, SD = 19.5). In contrast, samples from the forest sites had NO3-N concentrations ranging from < 0.1 mg/L to just over 1 mg/L. Mean NO3-N concentrations under the center pivot area were found to vary seasonally according to cropping and hydrologic patterns such that the mean values for March-May, June-August, September-November, and December-February were 7, 21, 27, and 21 mg/L, respectively. The lower value for March-May indicated that winter rains leached most of the root zone NO3-N beneath the wells by March, and that there was a 2 to 3 month lag between spring-applied N and its appearance in shallow groundwater. The study raises concern about shallow groundwater quality under intense multiple cropping systems on sandy soils. Although studies in this physiographic area of the Coastal Plain have shown that relatively impermeable subsoil horizons cause shallow groundwater to flow laterally to the larger drainage networks, and that alluvial forest then remove most of the N, the results of this study imply that groundwater NO3-N contamination could be a problem in other physiographic areas having sandy soils lacking such subsoil horizons. GREAT DRAIN ROBBERY,
F. Pearce.
New Scientist, Vol. 101, No. 1401, p 10-16, 15 March 1984. 4 Fig.

Descriptors: *Legislation, *Water pollution control, *Great Britain, Water pollution sources, Industrial wastes, Waste disposal, Waste dumps, Estuaries, Environmental effects, Tees Estuary.

Efforts on the part of the British government to legislate water pollution control are reviewed and cases are cited which suggest that these measures have in large part failed to have any real effect on the problem. The Control of Pollution Act was approved by parliament some 10 years ago. Over the past 30 years many of Britains worst polluters, the oil refineries, chemical works, steel plants and paper mills, have moved to the coasts and estuaries. Four government inquiries have been made as to how to clean up the Tees, Britain's most polluted estuary. Until last September local councils made most of the appointments to water authorities. The authorities are now wholly made up of ministers' nominees. Ministers appear to have a penchant for putting men from the top British companies onto the authorities. Specific examples of extreme cases of water pollution are cited. (Baker-IVI)

QUANTITATIVE AND QUALITATIVE CHARACTERISTICS OF URBAN DISCHARGE TO SMALL RIVER BASINS IN THE SOUTH WEST OF SWEDEN,
Lund Univ. (Sweden).
W. Hogland, and R. Berndtsson.
Nordic Hydrology, Vol. 14, No. 3, p 155-166, 1983. 11 Fig, 1 Tab, 5 Ref.

Descriptors: *Rainfall-runoff relationships, *Urban runoff, *Sweden, *Lund, *Water pollution sources, Phosphorus, Snowmelt, Industrial wastes, Pollutograph, Copper, Zinc, Lead.

In the southwest of Sweden a common type of recipient for urban discharge is small rivers and creeks. Due to large variations in flow of these recipients, the polluted discharge can have different effects on aquatic life. The most critical periods often occur during summer. This is due to the very low flow during summer and heavy rainstorms which flush gutters and sewage pipes of pollutants and may cause combined sewer overflows. The receiving water for the city of Lund, Hoje river, is a typical recipient of urban discharge and is representative for the southwest of Sweden. Variations in pollution concentrations often occur within short time-periods. High concentrations in urban storm water can usually be traced to local pollution-sources. Examples of extreme values of different pollutants in urban stormwater from Lund are given. The high phosphorus concentration was due to overflow. High copper and zinc concentrations were found in areas with corroding copper and zinc roofs. Usually 75% of all data occurs around a narrow interval. When concentration values are found outside this interval, there is likely to be a local pollution source responsible. Such infomation can be used as an indicator for random samples. (Baker-IVI)

DISPERSION OF POLLUTANTS IN SEMI-INFINITE POROUS MEDIA WITH UNSTEADY VELOCITY DISTRIBUTION,
Banaras Hindu Univ., Varanasi (India). Dept. of Mathematics.
N. Kumar.
Nordic Hydrology, Vol. 14. No. 3, p 167-178, 1983. 3 Fig, 1 Tab, 17 Ref.

Descriptors: *Path of pollutants, *Seepage, *Porous media, *Dispersion, Flow, Water quality management, Water pollution control, Mathematical equations, Velocity, Groundwater movement.

Analytical solutions are developed for the dispersion problem in nonadsorbing and adsorbing, semi-infinite porous media in which the flow is one dimensional and the average flow velocity is unsteady. The expression that states the direct relationship of the dispersion coefficient with seepage velocity is used to solve the unsteady dispersion flow problem by introducing a new time variable. The source concentration of the pollutant varies exponentially with time. The variation in seepage velocity with time is considered because of resistance in the flow. The graphical solutions are also obtained for a set of data assumed. The analytical expressions obtained are useful to the study of salinity intrusion in groundwater, helpful in making quantitative predictions on the possible contamination of groundwater supplies resulting from groundwater movement through buried wastes. In addition, they should prove useful for other processes such as ion exchange in soils and decay of organic substances. (Baker-IVI)

ATMOSPHERIC NUTRIENT LOADINGS TO THE VENETIAN LAGOON,
Politecnico di Milano (Italy). Ist. di Ingegneria Sanitaria.
M. Guigliano, and R. Cossu.
The Science of the Total Environment, Vol. 29, No. 1/2, p 49-63, July 1983. 4 Fig, 5 Tab, 17 Ref.

Descriptors: *Phosphorus, *Nitrogen, *Lagoons, *Venice, *Italy, Fallout, Eutrophication, Adriatic Sea, Nutrients, Air pollution, Water pollution sources, Path of pollutants, Rainfall.

For the Lagoon of Venice (Italy), an evaluation of the nutrient loads discharged from the atmosphere is of particular interest, both because there are clear symptoms of progressive eutrophication of the lagoon as a whole and because there are industries in the area which emit nitrogen and phosphorus compounds which can increase the quantities carried in the air. Samples were taken from four points near the center of the lagoon around the city of Venice, over a period of 30 months. Monthly samples of rainwater were collected and analyzed for chemicals that showed the presence of nutrients (all the forms of nitrogen and phosphorus). The relationships between the various analytical parameters, sampling area, extent of the rainfall, and wind directions were studied using correlation coefficient matrices. The total quantity of nutrients that the atmosphere contributes to the lagoon is quite substantial and should not be ignored in the chemical balance of the ecosystem. (Baker-IVI)

ABUNDANCE OF SOME MAJOR AND TRACE ELEMENTS IN HIGHLY POLLUTED SEDIMENTS FROM THE RHINE RIVER NEAR MAINZ, WEST GERMANY,
Mainz Univ. (Germany, F.R.). Inst. fuer Geowissenschaften.
C. B. Dissanayake, H. J. Tobschall, H. Palme, U. Rast, and B. Spettel.
The Science of the Total Environment, Vol. 29, No. 3, p 243-260, August, 1983. 5 Fig, 3 Tab, 42 Ref.

Descriptors: *River sediments, *Pollutants, *Rhine River, *West Germany, *Mainz, Zinc, Silver, Gold, Rare earth elements, Uranium, Thorium, Chromium, Mercury, Cadmium, Hafnium, Galvinium, Sediments, Organic compounds.

The Ginsheimer Altrhein, which is a cut-off channel of the River Rhine near Mainz, is highly polluted, receiving waste effluent form a large industrial region. Neutron activation analysis was used to determine the abundances of 40 elements, including the rare earths, in the surface sediments of the River Ginsheimer Altrhein. Samples taken from 5 stations along the river contained very high concentrations of some elements such as zinc, 7160 ppm; silver, 154 ppm; gold, 750 ppb; copper 260 ppm; mercury, 94 ppm; and chromium, 1780 ppm. Significant enrichment due to anthropogenic sources was not evident among thorium (4-9 ppm) or uranium (2-8 ppm). Chalcophile, siderophile and lithophile elements showed very high positive correlations with organic carbon while the rare earth elements of Th, Hf, Ca, K, Ga, and Sc had negative correlations. (Baker-IVI)

gical studies, Wastewater pollution, Wastewater treatment, Chlorination, Bacteria, Staphylococcus, Amoebae, Viruses, Reoviruses, Adenoviruses, Enteroviruses, Coxsackie virus, Poliovirus, Recreation, Great Lakes, Lake Ontario.

The recent closure of some Ontario beaches has prompted investigations into possible sources of contamination of Lake Ontario. The role of sewage treatment plant effluents in microbial pollution of suface waters was analyzed through raw sewage, nonchlorinated and chlorinated effluent, and receiving waters for bacteria, amoebae and viruses. Determinations of total staphylococci, Pseudomonas aeruginosa, total coliforms, fecal coliforms, and fecal streptococci, from the raw sewage and outflow pipes of three sewage treatment plants, indicated that these organisms had a 0.02 to 0.008% survival rate after chlorination. Naegleria sp. were isolated from the raw sewage and sewage effluent of all three plants and, at one plant, the amoebae were also recovered from the chlorinated effluent and the lake water. Viruses were detected in 100% (11/11) of raw sewage, 63% (5/8) of nonchlorinated effluent, 40% (4/10) of chlorinated effluent and 4% (1/23) of receiving water samples. The viruses, identified using direct electron microscopic examination in combination with immunoelectron microscopy, were found to be reo-, adeno-, and enterovirus, coxsackievirus A9, B2 and B4, and poliovirus types 2 and 3. This study demonstrates that sewage treatment plants may have a detrimental impact on the water quality of recreational beaches. (Murphy-IVI)

ASSOCIATION OF NAEGLERIA FOWLERI WITH THE CHEMICAL, MICROBIOLOGICAL AND PHYSICAL CHARACTERISTICS OF SOUTH AUSTRALIAN WATER SUPPLIES,
South Australian Health Commission, Adelaide.
A. Esterman, M. Dorsch, S. Cameron, D. Roder, and B. Robinson.
Water Resources, Vol. 18, No. 5, p 549-553, 1984. 6 Tab, 10 Ref, 2 append.

Descriptors: *Naegleria fowleri, *Chemical properties, *Physical properties, *Microbiologal studies, Water supply, Amoebae, Pathogens, Water quality, Ecological distribution, Physiological ecology, Australia, Primary amoebic meningoencephalitis.

Primary amoebic meningoencephalitis (PAM) is a rare, though rapidly fatal, infection of the meninges and brain caused by the amoeba Naegleria fowleri. Control samples were compared with 102 water samples containing this pathogen. Generally, two controls were available for each sample where N. fowleri was detected. Univariate comparisons revealed a positive association of N. fowleri with: (a) water temperature; (b) maximum and minimum air temperature; (c) bacterial colony counts at 20 and 35 degrees C; (d) the total coliform count; (e) amoebae other than Naegleria and (f) Naegleria sp. other than N. fowleri. By comparison, negative associations were evident with free and total chlorine residuals. A conditional logistic regression analaysis indicated that N. fowleri isolation was positively and independently associated with: (a) water temperature; (b) maximum air temperature; (c) bacterial colony counts at 35 degrees C; and (d) low free chlorine residual. Negative associations were found with high temperature tolerant Naegleria and Acanthamoeba, but it is considered that these findings may reflect laboratory technique, not genuine ecological relationships. Evidence is presented that probability of detecting N. fowleri would vary markedly with the changes in mean water temperatures and maximum daily air temperature that occur by season. On the basis of temperature variations alone, and assuming a constant free chlorine residual, it is estimated that the probability of N. fowleri occurring (at detectable levels) would be 53 times higher in summer, eleven times higher in autumn, and six times higher in spring, than it would be in the winter. These are very approximate estimations which may not apply to an individual sampling site, nor to periods of extreme temperature. While this is a preliminary study, statistical associations of N. fowleri with a variety of ecological measures have been quantified. More comprehensive and detailed studies are required to further clarify the ecological relationships of this organism. (Murphy-IVI)

Descriptors: *Rotaviruses, *Enteroviruses, *Drinking water, *Natural waters, Developing countries, Coliform, Coxsackie virus, Water quality, Standards, Potable water, Mexico.

Rotaviruses have been implicated as a major cause of childhood and traveler's diarrhea in developing countries. Since water is known to be a vehicle of transmission of other enteric viruses, we sought to determine if water could play a role in the transmission of rotavirus infections in a developing nation by applying recently developed techniques for the concentration of viruses from tapwater and environmental (lake, river, ocean and aqueduct) water in Mexico. In an initial survey during the rainy season in August 1978, rotavirus was detected in 10 of 10 drinking water samples and coxsackie B4 or B6 virus in 5 of 10. In a larger survey during the dry season in December 1979, rotavirus was recovered from 3 and enteric viruses from 8 of 21 drinking water samples. Water quality data, available for the 1979 survey, indicated that while many tapwater samples did not meet U.S. coliform standards, some samples containing infectious virus did. Our data suggest that current bacteriological water quality standards for potable water do not reflect viral contamination. (Author's abstract)

MEASUREMENT OF ELECTRON TRANSPORT SYSTEM (ETS) ACTIVITY IN FRESHWATER SEDIMENT,
Guelph Univ. (Ontario). Dept. of Environmental Biology.
J. T. Trevors.
Water Resources, Vol. 18, No. 5, p 581-584, 1984. 6 Fig, 2 Tab, 9 Ref.

Descriptors: *Electron transport system, *Sediment, Electrochemistry, Electron transport, Microbial degradation, Oxygen requirements.

Electron transport system (ETS) activity was measured in freshwater sediment at 4, 10 and 20 degrees C by following the reduction of 2-(p-iodophenyl)-3-(p-nitrophenyl)-5-phenyl tetrazolium chloride (INT) to iodonitrotetrazolium (INT-formazan). The rate of INT-formazan formation was dependent upon the incubation temperature and nutrient amendments. Electron transport system activity also correlated very highly with O2 consumption rates in the same sediment. (Author's abstract)

BACTERIA IN DISTRIBUTION SYSTEMS (LA FLORE BACTERIENNE DANS UN RESEAU DE DISTRIBUTION),
Compagnie Generale des Eaux, Paris (France).
M. M. Bourbigot, A. Dodin, and R. Lheritier.
Water Resources, Vol. 18, No. 5, p 585-591, 1984. 2 Fig, 7 Tab, 16 Ref.

Descriptors: *Bacteria, *Water distribution, Water quality, Drinking water, Disinfection, Bacterial analysis, Water treatment, Paris, France.

Water quality upkeep in distribution systems is a major concern of drinking water suppliers, especially where systems transport water through several thousand kilometers of pipelines. The Water Authority for the Paris Suburbs' decided to modify treatment at the Mery-sur-Oise drinking water production plant. The old line was upgraded by the addition of a raw water basin, two more ozonation stages, and activated carbon filtration. Pre-chlorination is no longer used at the plant. A study to assess the impact of these changes on the quality of water in the system was launched prior to the switchover. It involved the enumeration and identification of the germs in analyzed samples of river water, treated water and distributed water. The mean value of the total bacterial aftergrowth in the distribution system of the old line, at 20 degrees C exceeded the limit value of the European standards (100 germs/ml). Removal of the biodegradable fraction of organics during treatment probably limits the aftergrowth, in spite of lower post-chlorination dosages. Moreover, chlorine is now in the form of free chlorine. TOC removal has been increased slighty by the new line, but the permanganate consumption has been greatly reduced, from 1.5 to 0.5/mg at the plant outlet. In river water, the germs are mainly Escherichia, Aeromonas hydrophila, Acinetobacter calcoaceticus, Alcaligenes faecalis. Yersinia enterocolitica were isolated in 6% of the samples. At the plant outlet, the samples are mostly uncontaminated in analysis conditions. In the distribution system, the species isolated are Aeromonas hydrophila and Alcaligenes faecalis. Enterobacteriaceae and Pseudomonodaceae also contaminated the samples, but with a very low frequency (5%). Many acid-fast bacteria species were isolated in river water (M. fortuitum, M. chelonei, M. terrae and M. lactis). But no species were found in samples of 250 ml at the plant outlet. 39 acid-fast bacteria were isolated from 126 samples of distributed water. Most germs belong to Runyon's group II but were not identified. The onset of deterioration of bacteriological quality may be a criterion for selecting the regeneration cycle for activated carbon. SEDIMENTARY COPROSTANOL AND HYDROCARBON DISTRIBUTION ADJACENT TO A SEWAGE OUTFALL,
Mote Marine Lab., Sarasota, FL.
R. C. Brown, and T. L. Wade.
Water Resources, Vol. 18, No. 5, p 621-632, 1984. 9 Fig, 3 Tab, 38 Ref.

Descriptors: *Coprostanol, *Hydrocarbons, *Wastewater outfall, Fate of pollutants, Sediments, Indicators.

The concentrations of coprostanol and hydrocarbons were measured in the effluent from the Chesapeake-Elizabeth sewage treatment plant (STP) and surface sediments from the area surrounding the effluent discharge site. Most of the coprostanol (> 84%) and hydrocarbons (> 91%) were associated with particulates in the effluent. The area was found to be dynamic where changes in the percentage and distribution of fine grained sediments occur over periods of months and the movement of these sediments is an important determinant of the distribution of sewage derived contaminants. The Chesapeake-Elizabeth STP was found to be responsible for only 7% of the hydrocarbon contamination of the sediments in the study area. The sediment hydrocarbon distribution also indicates that the Bay Bridge tunnel may be a unique source of hydrocarbons to the lower Chesapeake Bay. This study shows the usefulness of coprostanol in providing a better understanding of the fate and importance of sewage derived contaminants in areas around sewage outfalls. (Author's abstract)

BEHAVIOR OF FE, MN, CU AND CD IN THE DUWAMISH RIVER ESTUARY DOWNSTREAM OF A SEWAGE TREATMENT PLANT,
National Oceanic and Atmospheric Administration, Seattle, WA. Pacific Marine Environmental Lab.
A. J. Paulson, R. A. Feely, H. C. Curl, and J. F. Gendron.
Water Resources, Vol. 18, No. 5, p 633-641, 1984. 6 Fig, 2 Tab, 34 Ref, 1 Append.

Descriptors: *Behavior, *Iron, *Magnesium, *Copper, *Cadmium, *Duwamish River,

Wastewater outfall, Estuaries, Chemical properties, Fate of pollutants, Seattle, Washington.

Although the fate of sewage-derived trace metals in fresh and marine waters is only beginning to be understood, their partitioning between dissolved and particulate phases is known to play an important role in determining their fate. The behavior of dissolved Fe, Mn, Cu and Cd in the Duwamish River downstream of a sewage treatment plant located near Seattle, Washington, was investigated in three distinct zones: (1) immediately downstream of the effluent outfall, (2) further downstream in the freshwater portion of the river and (3) in the estuaring mixing zone. A three-end-member tracer model utilizing salinity and dissolved inorganic nitrogen was developed to distinguish physical mixing process from biogeochemical reactions. The results of this investigations indicate that Fe was removed from the dissolved phase onto particulates near the plant. Although no additional reactions controlled the distribution of dissolved Fe, Mn and Cu in the freshwater portion of the river, Cd was removed from the dissolved phase. In the estuarine mixing zone, a significant fraction of the dissolved Fe and Cu was removed from solution, while Mn and Cd desorbed from particulates. The chemical forms of the trace metals rather than their sources appear to determine their participation in these reactions. (Murphy-IVI)

RESIDUES OF ORGANOCHLORINE INSECTICIDES, POLYCHLORINATED BIPHENYLS, AND HEAVY METALS IN BIOTA FROM APALACHICOLA RIVER, FLORIDA, 1978,
Georgia Univ., Athens.
P. V. Winger, C. Sieckman, T. W. May, and W. W. Johnson.
Journal Association of Official Analytical Chemists, Vol. 67, No. 2, March-April, 1984. 3 Fig, 8 Tab, 28 Ref.

Descriptors: *Organochlorine insecticides, *Polychlorinated biphenyls, *Heavy metals, *Biota, *Apalachicola River, Insecticides, DDT, Toxaphene, Organic compounds, Organic pesticides, Standards, Water pollution, Fate of pollutants, Bioindicators, Florida.

Seventy-seven composite samples composed of largemouth bass (Micropterus salmoides), channel catfish (Ictaluras punctatus), threadfin shad (Dorosoma petenense), Asiatic clam (Corbicula Fluminea), burrowing mayfly (Hexagenia sp.), water snake (Natrix spp.), and little green heron (Butorides virescens) were collected from upper and lower reaches of the Apalachicola River, Florida, in 1978 for residue analysis of organochlorine insecticides, PCBs (polychlorinated biphenyls), and metals. Compared with data from the National Pesticide Monitoring Program and criteria recommended for the protection of aquatic life, residue concentrations were moderately high in the Apalachicola River. Biota from the upper river generally had higher organic and lower metal residues than those from the lower river. Highest residues in the biota were total DDT, total PCBs, and toxaphene. Although individual mean concentrations were below 2 microg/g and total organic contaminant residues never exceeded 5 microg/g, residue concentrations of DDT, PCBs, and toxaphene (particularly from the upper river) exceeded recommended permissible levels for the protection of aquatic life. Metal residues were generally below 1 microg/g. Exceptions were arsenic residues in threadfin shad (1.07 microg/g) and Asiatic clams (1.75 microg/g), and selenium in eggs of channel catfish (1.39 microg/g). The residues observed in the biota, particularly from the upper station, indicated moderate contamination of the Apalachicola River system at the time samples were collected. (Author's abstract)

ADSORPTION OF HYDROPHOBIC POLLUTANTS IN ESTUARIES,
Manhattan Coll., Bronx, NY. Environmental Engineering and Science Program.
J. P. Connolly, N. E. Armstrong, and R. W. Miksad.
Journal of Environmental Engineering, Vol. 109, No. 1, p 17-35, February, 1983. 13 Fig, 2 Tab, 23 Ref.

Descriptors: *Fate of pollutants, *Kepone, *Estuaries, *Adsorption, Suspended sediments, Simulation, Model studies, Tidal effects, Resuspension, Mathematical models, Pesticides.

Using Kepone as the test compound, the relation of sediment suspension to fate of hydrophobic pollutants through adsorption is examined. Adsorption experiments show rapid attainment of an equilibrium condition that is a linear function of dissolved Kepone concentration and an inverse non-linear function of adsorbing solids concentration. An apparatus creating a one-dimensional distribution of suspended sediment over a sediment bed is used to experimentally simulate an estuarine tidal cycle during which the transfer of Kepone from the bed to water column is examined. A mathematical model of the adsorption and sediment resuspension process is used to analyze the experimental results. Resuspension and the variation of adsorption equilibrium with solids concentration are shown to be significant to the transfer. Adsorption kinetics are not significant because of the rapid approach to equilibrium. (Author's abstract)

ORGANIC CARBON DECAY IN STREAM WITH BIOFILM KINETICS,
Montana State Univ., Bozeman. Dept. of Civil Engineering and Engineering Mechanics.
S. Srinanthakumar, and A. Amirtharajah.
Journal of Environmental Engineering, Vol. 109, No. 1, p 102-119, February, 1983. 14 Fig, 42 Ref.

Descriptors: *Biofilms, *Microorganisms, *Fate of pollutants, *Kinetics, *Mathematical models, *Organic carbon, Decomposition, Streams, Wastewater, Biomass, Velocity, Water temperature.

The importance of sessile microbial populations in aquatic environments has been recognized for many years especially the heterotrophic slimes under polluted conditions. However, models proposed by previous researchers to predict substrate decay rates have been based on first order or Monod kinetic expressions describing substrate utilization by suspended biomass. The investigation carried out looks at two important aspects of organic carbon modeling in a shallow stream: (1) it compares the importance of suspended microbial populations to the biofilm community and (2) it determines the kinetics of organic carbon uptake rate by river biofilms using an artificial stream channel. The results confirmed the dominance of attached microbial films in removing organic carbon in a shallow turbulent river. The study provided the organic carbon uptake rate (RB) and the net scour rate (RD) for the biofilms while establishing the validity of first order kinetics in a specified range of substrate concentrations, flow velocity and temperature. Mathematical models were formulated and verified under steady state conditions for the organic carbon and biomass change below a sewage outfall in a selected river system. (Author's abstract)

MOST RAPID BOD ASSIMILATION IN GANGA AND YAMUNA RIVERS,
Roorkee Univ. (India). Dept. of Civil Engineering.
D. S. Bhargava.
Journal of Environmental Engineering, Vol. 109, No. 1, p 174-188, February, 1983. 7 Fig, 6 Tab, 16 Ref.

Descriptors: *Biochemical oxygen demand, *Fate of pollutants, *Ganga, *Ganges, *Yamuna, *India, Bioflocculation, Aeration, Dissolved oxygen, Municipal wastewater, Mathematical models, Kinetics.

During a water quality survey of the Ganga and Yamuna of the Indogangetic plain, the assimilation of biochemical oxygen demand (BOD) after the waste outfalls at the urban centers along these rivers was found to be exceedingly fast. During the two-stage BOD removal in these streams, the early reaches resulted from bioflocculation of waste colloidal matter with river water. It was found to follow a straight line law approximately a BOD rate constant (k) of as high values as 30 to 100 day-1 (base e) resulting in about 60% BOD removal in 30 min-60 min. In the later reaches, the BOD removal was found to follow the usual first order kinetics with k ranging from 1.5 to 5.5/day (base e) which are higher by an order of magnitude than the usual range of 0.2 to 0.5/day (base e). The dissolved oxygen (DO), which dropped to low values after the waste outfalls, was also found to recover in short times showing extremely fast reaeration. Such BOD exertion and reaeration have been modelled. The integrated effect of several drains releasing at an urban center has also been included in the prediction of BOD and DO. (Author's abstract)

RAIN AND SNOW SCAVENGING OF HNO3 VAPOR IN THE ATMOSPHERE,
Ford Motor Co., Dearborn, MI. Research Staff.
T. Y. Chang.
Atmospheric Environment, Vol. 18, No. 1, p 191-197, 1984. 30 Ref.

Descriptors: *Rainfall, *Scavenging, *Water pollution sources, Nitrates, Precipitation, Air pollution, Acidity, Acid rain, Precipitation rate, Snow.

Wet removal coefficients for HNO3 vapor from the atmosphere by rain (in-cloud and below-cloud, washout) and snow have been derived under a number of approximations. The coefficients are parameterized in terms of precipitation rate. The coefficients represent average scavenging from large precipitation bands or frontal systems over horizontal scales of 50 km or more where there is widespread weakly ascending air motion. Because a number of approximations are involved in the derivation of these coefficients, there exist significant uncertainties in the derived expressions, particularly in the snow scavenging coefficients. The derived coefficients would be appropriate, on an interim basis, for inclusion into regional or mesoscale models which include the wet removal of HNO3 vapor. When combined with altitude-dependent precipitation rates and vertical profiles of HNO3 concentrations, these coefficients are also useful to estimate the flux of HNO3 to the earth's surface. The derived snow scavenging coefficients are consistent with those of recent measurements. Rain and snow scavenging coefficients are also consistent with recent observations of ionic composition in winter precipitation samples which indicates that snow removes HNO3 vapor more efficiently than rain. (Baker-IVI)

MODEL FOR SULPHATE IN STREAMWATER AT STORGAMA, SOUTHERN NORWAY,
Sentralinstitutt for Industriell Forskning, Oslo (Norway).
N. Christophersen, L. H. Dymbe, M. Johannssen, and H. M. Seip.
Ecological Modelling, Vol. 21, No. 1 and 2, p 35-61, 1983/1984. 13 Fig, 4 Tab, 39 Ref.

Descriptors: *Sulfate, *Path of pollutants, Norway, Storms, Rainfall, Runoff, Storgama, Model studies, Snowpack, Snowmelt, Seasonal variations, Streams, Telemark county.

The sulfate budget and a model for sulfate concentrations in streamwater have been established for a small, gauged catchment in Telemark county, southern Norway. The annual input roughly balances the output. The average annual flux through the catchment for four years is about 3500 mg

sulfate/sq m. Typical seasonal trends, such as the fairly stable winter concentrations and the decrease during melting, are reproduced in a model which is based on a simple reservoir hydrologic model. In the model, water-soluble sulfate accumulated in the reservoir representing the surface soils during dry periods because of dry deposition, evapotranspiration of summer rainfalls and mineralization. During wet summer periods, water-soluble sulfate is removed due to reduction adsorption. The concentration pattern during snowmelt is largely dependent on the fractionation of sulfate held by the snowpack. The model is particularly useful as a data interpretation tool. The difference between wet and dry summers is also clearly shown. A systematic discrepancy occurs in the initial phase of the snowmelt where the predicted concentrations are always too low. EFFECTS OF ACID RAIN ON WATER SUPPLIES IN THE NORTHEAST,
New England Water Works Association, Dedham, MA.
F. B. Taylor, and G. E. Symons.
American Water Works Association Journal, Vol. 76, No. 3, p 34-41, March, 1984. 4 Fig, 13 Tab, 17 Ref.

Descriptors: *Acid rain, *Public health, *Drinking water, Aquifers, Watersheds, New England, Groundwater, Surface waters, Precipitation, Corrosion, Economic factors.

Surface water and groundwater supplies were sampled in New England, and some sites in the Northeast and the Appalachians to determine the impacts of acid precipitation on drinking water, in terms of health effects in humans. During this study the adverse effects of acid rain on human health through ingestion of surface water supplies was not demonstrated, but the data show that unadjusted aluminum content in a number of supplies could be a problem to patients on kidney dialysis. Though the quantification remains to be established, it is reasonable to assign some part of the highly corrosive nature of New England waters to acidic deposition because of the poorly buffered watersheds and aquifers. Historical data, as demonstrated in the case described showed that highly aggressive waters have been encountered for a long time. A system for classifying watersheds and aquifers is proposed. FIELD MONITORING OF CHRYSOTILE ASBESTOS IN CALIFORNIA WATERS,
California Dept. of Health Services, Berkeley. Air and Industrial Hygiene Lab. Section.
S. B. Hayward.
Journal of the American Water Works Association, Vol. 76, No. 3, p 66-73, March, 1984. 9 Fig, 7 Tab, 29 Ref.

Descriptors: *Asbestos, *California, *Drinking water, Water supply, Serpentine, Watersheds, Water pollution sources, Reservoirs, Seasonal variation, Water treatment, Coagulation, Turbidity.

Asbestos contamination in sources of drinking water in the state of California is being monitored. Contamination of surface water supplies draining serpentine-containing watersheds of being stored in reservoirs in contact with serpentine deposits is usually >100 MFL and has been found to be as high as 200,000 MFL. Concentrations in water supplies draining serpentine-containing watershed exhibit seasonal variations, with the largest concentrations occurring during or just following heavy rains in the watershed. Some of the concentrations were the highest measured anywhere in the world. Asbestos was also found in groundwater taken from wells that are recharged through serpentine rock. Water treatment was found to have widely varying success in the removal of asbestos fibers. Reduction by a factor of 50,000 was observed as a result of conventional coagulation-filtration in one case. Data on treatment suggest that the percentage removal of fibers depends on the initial concentration. Asbestos concentrations have been found to correlate well with turbidity in only a few limited cases. (Moore-IVI)

NATIONWIDE ASSESSMENT OF URBAN RUNOFF IMPACT ON RECEIVING WATER QUALITY,
Florida Water Resources Research Center, Gainesville.
J. P. Heaney, and W. C. Huber.
Water Resources Bulletin, Vol. 20, No. 1, p 35-42, February, 1984. 2 Fig, 5 Tab, 14 Ref. EPA grant 805663.

Descriptors: *Urban runoff, *Combined sewer overflows, *Environmental effects, *Water quality, Water pollution effects, Fish kills, Beaches, Dissolved oxygen, Storm runoff.

Urban stormwater runoff has been recognized as a potential major contributor of pollution to receiving waters. However the projected high costs of control have prompted an examination of the extent to which these impacts have been documented. A nationwide search was conducted for case studies demonstrating a cause-effect linkage between urban runoff and impairment of beneficial uses in receiving waters. Documented case studies of impacts of urban runoff and combined sewer overflows on receiving water are scarce. Impacts of other discharges mask the impacts of urban runoff, and the expected impacts from urban runoff are relatively subtle. The existance of numerous definitions of the word 'impact' make it difficult to devise meaningful rankings of impacts. No clear line of demarcation exists to destinguish the urban drainage system from the receiving water, especially for small creeks and ponds. Some evidence exists that urban runoff is a cause of fish kills and beach closings. The studies of dissolved oxygen records downstream of urban areas have produced the most definitive information regarding the impact of wet weather flows. Stormwater discharges dampen the diurnal fluctuations in dissolved oxygen and can reduce the overall dissolved oxygen levels. If receiving water impacts are to be evaluated for environmental decision making, then a problem solving framework is needed. (Moore-IVI)

FECAL COLIFORM RELEASE FROM CATTLE FECAL DEPOSITS,
Utah State Univ., Logan. Coll. of Natural Resources.
M. Kress, and G. F. Gifford.
Water Resources Bulletin, Vol. 20, No. 1, p 61-66, February, 1984. 7 Fig, 24 Ref. OWRT project JNR 048-Utah.

Descriptors: *Feces, *Coliforms, *Cattle, *Water pollution sources, Fecal coliforms, Rainfall intensity, Bacteria.

Cowpies molded to a standard configuration and size were subjected to simulated rainfall, and the fecal coliform counts were determined using the most probable number (MPN) method of enumeration. The standard cowpie deposits were exposed to simulated rainfall once at ages 2 through 100 days. The effects of rainfall intensity and recurrent rainfall were also tested. Naturally-occurring fecal deposits were also tested to compare their results with those from the standard cowpies. A log-log regression was found to describe in peak fecal coliform release with fecal deposit age. The 100-day-old fecal deposits produced peak counts of 4,200 fecal coliform per 100 milliliters of water. This quantity of release is minimal compared to the release from fresher fecal material. Rainfall intensity had little effect on peak fecal coliform release from fecal deposits that were 2 or 10 days old. At age 20 days the effect of rainfall intensity was significant; the highest intensity gave the lowest peak counts, and the lowest intensity gave the highest peak counts. The effect of rainfall intensity appears to be related to the dryness of the fecal deposits. Peak fecal coliform counts were significantly lower when the fecal deposits were rained on more than once. This decline was thought to be produced by the loss of bacteria from the fecal deposits during the previous wettings. Standard cowpies produced a peak release regression that was not significantly different from the regression for the natural fecal deposits. Apparently, grossly manipulating the fecal deposits did not significantly change the release patterns. (Author's abstract)

DENITRIFICATION: ITS IMPORTANCE IN A RIVER DRAINING AN INTENSIVELY CROPPED WATERSHED,
York Univ., Toronto (Ontario). Dept. of Geography.
A. R. Hill.
Agriculture, Ecosystems and Environment, Vol. 10, No. 1, p 47-62, August, 1983. 2 Fig, 4 Tab, 36 Ref.

Descriptors: *Nitrogen, *Water pollution sources, *Fate of pollutants, *Nottawasaga River, *Ontario, Fertilizers, Nitrates, Groundwater pollution, Denitrification, Sediments, Path of pollutants.

Nitrogen transport was studied during summer low flows in a 20-km reach of the Nottawasaga River (Ontario) which drains an intensively cropped sand plain which has an underlying shallow water-table aquifer. Nitrogen inputs to the river were measured on 30 days in May to October of 1977-81. These data indicated that about 38% of the daily nitrate input entered the river through ground water. The magnitude of this input is a consequence of widespread contamination of the shallow aquifer by nitrogen fertilizer. Ground water entering the river from springs and seeps near fertilized fields frequently contained more than 10 mg/l of NO3-N. Mass balance studies of nitrogen transport in the river revealed an average daily nitrate loss of 46 + or - 23 kg N. This rate of nitrate removal represented about 40% of the ground water input to the river from the sand plain. Analysis of a mass balance for total Kjeldahl nitrogen revealed an essentially balanced budget, whereas chloride showed a small daily gain of about 5%. Laboratory experiments involving the incubation of stream sediment cores and the use of the acetylene block technique suggested that the bulk of the nitrate loss during river transport was caused by denitrification in bottom sediments. DISPERSION SCALE EFFECT IN MODEL CALIBRATIONS AND FIELD TRACER EXPERIMENTS,
Texas A and M Univ., College Station. Dept. of Geology.
P. A. Domenico, and G. A. Robbins.
Journal of Hydrology, Vol. 70, No. 1-4, p 123-132, 1984. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Dispersion, *Model studies, *Tracers, Groundwater pollution, Path of pollutants, Dispersivity, Model scale, Plumes.

Field tracer experiments and model calibrations indicate that the magnitude of dispersivity increases as a function of the scale at which observations are made. Calculations presented in this study suggest that some part of this scaling may be explained as an artifact of the models used. Specifically, a scaling-up of dispersivity will occur whenever an (n - 1)-dimensional model is calibrated or otherwise employed to describe an n-dimensional system. The calibrated coefficients for such models will depend not only on size of the contaminant plume or tracer experiment at the time of calibration, but will exhibit a size dependency beyond the calibration period. The magnitude of scaling appears to be sufficient to encompass the range of differences between laboratory measurements of

dispersivity and model calibrations. (Author's abstract)

RAPID PREDICTION OF THE EXTENSION OF POLLUTION IN SOME CASES OF EFFLUENT AND METHOD OF INJECTION (PREVISION RAPIDE DE L'EXTENSION D'UNE POLLUTION DANS QUELQUES CAS D'ECOULEMENT ET DE MODE D'INJECTION),
Lille-1 Univ., Villeneuve d'Ascq (France). Lab. de Geologie Appliquee.
N. Crampon.
Journal of Hydrology, Vol. 70, No. 1-4, p 149-165, 1984. 4 Fig, 9 Ref.

Descriptors: *Path of pollutants, *Dispersion, Groundwater pollution, Wells, Saturated flow, Groundwater movement, Mathematical models.

The relationship between maximum concentration and longitudinal distance, independent of time, can determine the size of the area to be contaminated, under well-defined conditions of injection and flow in a saturated medium. The envelope curve for maximal concentrations is easily obtained as a function of the axial distance in nondimensional variables in the cases of one- and two-dimensional uniform flow, as well as in those of radially symmetric converging or diverging flow. Graphs providing relations between dimensionless variables are given for the following cases: (1) uniform flow with instantaneous discharge of a pollutant; measurement downstream of the injection point, no transverse dispersion; (2) uniform flow with continuous injection of a pollutant; measurement downstream of the injection point, influence of transverse dispersion included; (3) convergent radial flow towards as well; pollution caused by an instantaneous point-source at some distance; and (4) divergent radial flow from an injection point; pollution caused by instantaneous injection of a pollutant. ANALYTICAL SOLUTION FOR CHEMICAL TRANSPORT WITH NONEQUILIBRIUM MASS TRANSFER, ADSORPTION AND BIOLOGICAL TRANSFORMATION,
Institut Fotosinteza, Pushchino (USSR).
E. V. Mironenko, and Ya. A. Pachepsky.
Journal of Hydrology, Vol. 70, No. 1-4, p 167-175, 1984. 1 Fig, 1 Tab, 29 Ref.

Descriptors: *Path of pollutants, *Nitrates, Denitrification, Model studies, mathematical equations, Solute transport, Sorption.

An analytical solution is presented for the set of equations describing chemical transport in soils with dispersion, presence of a stagnant liquid phase and sorption, in which the solute is involved in biological or chemical transformations. The model is used for description of nitrate transport and denitrification in a soil column. Both the case of constant input concentration of migrant and the case of a concentration pulse were considered. (Baker-IVI)

DISTRIBUTION, SOURCE AND EVOLUTION OF NITRATE IN A GLACIAL TILL OF SOUTHERN ALBERTA, CANADA,
Department of Agriculture, Lethbridge (Alberta).
M. J. Hendry, R. G. L. McCready, and W. D. Gould.
Journal of Hydrology, Vol. 70, No. 1-4, p 177-198, 1984. 10 Fig, 6 Tab, 43 Ref.

Descriptors: *Nitrates, *Glacial till, *Alberta, *Water pollution sources, *Groundwater pollution, Tritium, Bacteria, Denitrification.

This paper addresses the distribution, origin and controls upon nitrate in a 30-sq km area of the Interior Great Plains Region of southern Alberta, Canada. High concentrations of nitrate (>100 mg/l NO3(-)-N) occurred in several isolated enclaves below the water table in brown weathered till. Nitrate concentrations of over 300 mg/l(-)-N were encountered in groundwater samples collected from these enclaves. Low nitrate concentrations (<1.1 mg/l NO3(-)-N) were also encountered in the weathered till upgradient and downgradient of the nitrate enclaves. Groundwater samples collected from the underlying grey nonweathered till and bedrock had NO3(-)-N concentrations of <1.1 mg/l. Through the application of geochemical (NO3(-)-N and NH4(+)-N) studies, environmental isotope studies (tritium), microbial analyses (nitrifiers) and laboratory experiments, it was shown that the high nitrates found in the weathered till are the result of the oxidation of ammonium present within the tills. It is postulated that this oxidation occurred during the Holocene epoch when water tables were much lower than present-day levels (5-18 m, and 2 m below ground, respectively). Through the use of Eh measurements, the enumeration of denitrifying bacteria and laboratory experiments, the potential for denitrification was shown to exist below the present-day water table in the weathered till as well as in the nonweathered till and bedrock. Isotopic data showed that less dentrification may be occurring within the nitrate enclaves than in adjacent downgradient areas. (Author's abstract)

LEACHING OF ALDICARB AND THIOFANOX, AND THEIR UPTAKE IN SOILS BY SUGARBEET PLANTS,
Ghent Rijksuniversiteit (Belgium). Dept. of Crop Protection Chemistry.
W. Dejonckheere, W. Steurbaut, G. Melkebeke, and R. H. Kips.
Pesticide Science, Vol. 14, No. 2, p 99-107, April, 1983. 9 Tab, 15 Ref.

Descriptors: *Leaching, *Insecticides, *Beets, Path of pollutants, Irrigation, Aldicarb, Thiofanox, Pesticide residues.

The leaching of aldicarb and thiofanox in soils (sandy loam, silt loam and sandy clay loam), and their uptake by sugarbeet plants were studied. Three irrigation levels were maintained: half, normal and double dose. The residues were determined as the sum of the insecticidal metabolites (parent compound + sulfoxide + sulphone) for both pesticides. Leaching was greatly influenced by the amount of water added and the soil type. Under normal conditions, leaching seemed to proceed very slowly, keeping the chemicals available for uptake by the root systems for a long time. The concentration of insecticide in the leaves was highest in beets grown on sandy loam and lowest in those grown on sandy clay loam. The quantity of irrigation did not influence the residue concentration in the leaves greatly, although its influence was obvious on the total residue present (micro g per plant). Increasing the water dose always resulted in a higher total residue, and a greater plant weight. The breakdown in the soils was directly related to the water dose. The experiments show that thiofanox was more stable than aldicarb and was taken up by sugarbeet to a greater extent. (Author's abstract)

HERBICIDE RESIDUES IN WASTE WATERS FROM RICEFIELDS,
Cagliari Univ. (Italy). Facolta de Farmacia.
P. Cabras, P. Diana, M. Meloni, F. M. Pirisi, and R. Pirisi.
Pesticide Science, Vol. 14, No, 2, p 130-134, April, 1983. 1 Fig, 3 Tab, 10 Ref.

Descriptors: *Pesticide residues, *Herbicides, *Insecticides, *Rice, Wastewater, Water pollution sources, Pesticide residues.

The potential pollution of the ricefields by herbicides can be defined by the empirical quantity theoretical maximum concentration (TMC), which is the concentration of the herbicides in the water when their sprayed amounts are dissolved in an average depth of water (about 20 cm). The herbicides bentazone, 2,4-D, MCPA, propanil, molinate, and tiocarbazil, and the insecticide phenthoate, were applied to ricefields at rates equivalent to maximum aqueous concentrations of 0.4-2.8 mg/kg, assuming the water to be 20 cm deep. Their concentrations in water were measured by high-performance liquid chromatography. The TMC values are compared with the corresponding LC50 values for fish, the water solubility, and the minimum detectable value (MDV) achievable with the analytical technique used. All of the MDVs were at least 100 times lower than the TMC values. The TMC values are less than their water solubility. They are also lower than the LC50 values for fish, except for propanil. Residues in 162 water samples, collected from 16 ricefields, 1, 4, 7, 10, 12, 18, 21 and 120 days after the last spraying, were all below the limit of determination (0.03 mg/kg). Residues in 40 water samples taken from five drainage canals were also less than 0.03 mg/kg. (Moore-IVI)

Descriptors: *Acid rain, *Aquatic animals, *Water pollution effects, Acidity, Invertebrates, Snowmelt, Rainfall, Nitrates, Sulfates, Germany, Kassel, Brooks, Land use, Hydrogen ion concentration.

Five small brooks in the Kaufunger Wald (near Kassel, West Germany) with different degrees of acidification were chemically and biologically investigated in a wooded red stone area near Kassel within a period of two years. The acidification may be due to acid precipitation, land use changes and cation exchange in humic substances with the first cause being the suspected major one. Recorded pH-minima were always connected with times of heavy rainfall or snow melt. Eighty species of aquatic invertebrate fauna were collected in a neutral brook. In a weakly acidic brook, only 42 of these species were present, and in the strongly acid brooks with mean pH levels of 4.7, 4.5, and 4.1, only 21, 17, and 15 species were found respectively. In the Kaufunger Wald, the hydrogen ion concentration operates directly to restrict the benthic invertebrate fauna. (Baker-IVI)

HYDROCHEMICAL STUDIES OF THE VELIKA MORAVA RIVER AND ITS TRIBUTARIES (HYDROCHEMISCHE UNTERSUCHUNGEN DER VELIKA MORAVA UND IHRER NEBENFLUSSE),
Institute for Biological Research, Belgrade (Yugoslovia).
G. Petrovic.
Archiv fur Hydrobiologie, Suppl. 68, No. 1, p 1-14, October, 1983. 16 Fig, 5 Tab, 5 Ref.

Descriptors: *Water pollution effects, *Rivers, *Sediments, Water quality, Velika Morava River, Yugoslavia, Drainage basins, Domestic wastes, Industrial wastes, Water pollution sources, Cadmium, Chromium.

Velika Morava is the largest tributary of the Danube in Serbia (Yugoslavia). Hydrochemical studies of water and sediments of the Velika Morava and its tributaries - the Kalenicka, Lugomir, Belica and Resava Rivers, as well as of its constituent rivers, the Zapadna and Juzna Morava, have been made to assess the water quality in the drainage basin of the main river. The levels of cadmium and chromium in the sediments of Velika Morava are elevated. Both industrial and domestic waste waters are impairing the quality of the waters studied to such a degree that adequate measures are needed for their protection, which

eventually would contribute to the protection of the Danube. (Baker-IVI)

NITRIFICATION IN THE RIVERS MOSELLE AND DANUBE (ZUR NITRIFIKATION IN MOSEL UND DONAU),
D. Mueller, and V. Kirchesch.
Archiv fur Hydrobiologie, Suppl. 68, No. 1, p 63-76, October, 1983. 4 Fig, 2 Tab, 17 Ref.

Descriptors: *Nitrification, *Moselle River, *Danube River, Ammonium, Water pollution effects, Biochemical oxygen demand, Dissolved oxygen, Bacteria.

Longitudinal profiles for the BOD-5 of the River Moselle and for the BOD-7 of the Danube demonstrate that the oxygen demand caused by nitrification is an important part of the BOD. The rate of nitrification in the Danube amounts to about 0.1 mg/l/day, which is a quarter of the rate in the Moselle, though the difference between the concentrations of ammonium in the two rivers is much higher (Moselle 2 mg/l, Danube 0.2 mg/l). The rates per volume of the nitrifying bacteria attached to the river bed are calculated to be 0.6 mg/l/day for the Moselle and 0.1 mg/l/day for the Danube. The significance of nitrification in the water development and management practice for the Moselle lies in its reducing effect on the concentration of ammonium and on the oxygen consumption. The decrease in oxygen content was of special importance because of its contribution to summer fish mortality. In the Danube nitrification prevents the enrichment in ammonium. (Baker-IVI)

SEASONAL AND LONG-TERM CHANGES IN THE HYDROBIOLOGY OF THE LAM TSUEN RIVER, NEW TERRITORIES, HONG KONG, WITH SPECIAL REFERENCE TO BENTHIC MACROINVERTEBRATE DISTRIBUTION AND ABUNDANCE,
Hong Kong Univ. Dept. of Zoology.
D. Dudgeon.
Archiv fur Hydrobiologie, Suppl. 69, No. 1, p 55-129, January, 1984. 38 Fig, 6 Tab, 146 Ref.

Descriptors: *Benthic environment, *Seasonal variations, *Lam Tsuen River, *Hong Kong, Species distribution, Macrobenthos, Bottom sediments, Eutrophication, Invertebrates, Aquatic animals.

Water quality varied along the river, with middle and lower course sites showing signs of slight cultural eutrophication in 1976. In 1978-79, the extent of organic enrichment of the river had increased at all but two upper reach stations. Temporal variations in water quality in 1978-79 were associated with changing river discharge resulting from Hong Kong's seasonal rainfall. The number of taxa and the diversity of macrobenthic communities decreased downstream in 1976 and 1978-79 while faunal abundance showed no such trend. The effects of increased cultural eutrophication in 1978-79 were reflected by large increases in macrobenthic population densities and a general decrease in faunal diversity. Lam Tsuen River sediments showed downstream changes in physical characteristics, tending towards decreased mean grain size, increased sorting and decreased skewness and kurtosis. The patterns of macroinvertebrate zonation, and sedimentary and hydrological characteristcis of the Lam Tsuen River, can be interpreted as reflecting transfers of material (nutrients, agricultural wastes, sewage) to the aquatic habitat from the surrounding terrestrial environment. Land use patterns around the Lam Tsuen River profoundly affect aquatic communities through the medium of such transfers by altering community structure as well as the distribution and abundance of individual taxa. PRODUCTION OF A STREAM SHREDDER, PELTOPERLA MARIA (PLECOPTERA: PELTOPERLIDAE) IN DISTURBED AND UNDISTURBED HARDWOOD CATCHMENTS,
Georgia Univ., Athens. Dept. of Entomology.
J. O'Hop, J. B. Wallace, and J. D. Haefner.
Freshwater Biology, Vol. 14, No. 1, p 13-21, February, 1984. 2 Fig, 4 Tab, 36 Ref.

Descriptors: *Peltoperla maria, *Population density, *Streams, Ecosystems, Population dynamics, Catchment areas, Comparison studies, Appalachia, Insect behavior.

The average benthic density of Peltoperla maria in an undisturbed southern Appalachian stream was more than twice that of a nearby stream draining a previously clear-cut catchment in its tenth year of natural secondary succession. Peltoperla production estimates, using three methods, do not show a significant difference in production between streams draining the two catchments. This is attributed to quicker growth and slightly higher densities of larger nymphs in the disturbed stream. Production estimates for the disturbed stream ranged from 498 to 560 mg (ash free dry weight)/sq m/y while those for the undisturbed stream were 414-515 mg/sq m/y. These results reinforce the view that conclusions based solely upon numerical densities may lead to erroneous interpretations about the roles organisms play in ecosystems. Annual frass production by this shredder is about 20 times (10 g/sq m/y) the secondary production of P. maria. (Murphy-IVI)

Descriptors: *Volcanic ash, Fish, *Herring, *Pacific herring, *Fish eggs, *Fish larvae, Sedimentation, *Suspended solids, *Suspended sediment, Estuaries, *Estuarine fisheries, Fisheries, *Mt. St. Helens, *Columbia River Estuary.

Potential effects of volcanic ash from Mt. St. Helens eruption upon early life history stages of Pacific herring, Clupea harengus pallasi, a species which spawns demersal eggs in the lower Columbia River estuary, were assessed and compared with effects of uncontaminated estuarine sediment. Three life stages were considered: developing eggs, yolk-sac larvae, and newly feeding larvae. Settling of ash or sediment on developing eggs at increasing suspension concentrations slowed development and caused mortalities to approach 100%. Smothering due to oxygen deprivation was more dramatic with sediment than ash. Suspensions continuously maintained throughout incubation allowed a fine layer of sediment or ash to accumulate on eggs but did not affect mortality rates and development times. Newly hatched yolk-sac larvae were not affected by 24-hour exposure to suspensions. However, high suspension concentrations caused slight increases in mortality if larvae were subsequently held in clean water; abrasion appeared to be responsible and was greater with ash than sediment. Ash and sediment suspensions affected the feeding incidence and mean number of food items consumed by feeding larvae, apparently promoting feeding by providing contrast between prey items and surrounding water. Overall, volcanic ash and estuarine sediment at environmentally realistic suspension concentrations did not severely affect herring larvae. The greatest threat appears to be egg smothering and resultant increased mortality.

BIOACCUMULATION MONITORING IN THE NEW YORK BIGHT USING THE BLUE MUSSEL (MYTILUS EDULIS),
Army Engineer District, New York.
S. J. Koepp, D. E. Santoro, R. Zimmer, J. E. Nadeau, and L. Ciaccio.
Final Report, New Jersey Marine Sciences Consortium, March, 1982. 41 p, 1 Fig, 73 Ref, 9 Append.

Descriptors: *Bioaccumulation, *Tissue analysis, *Ocean dumping, *Contamination, *Mussels, *Mytilus, *Chemical wastes, *Bights, Harbors, Heavy metals, Lead, Petroleum hydrocarbons, Metals, Dredging.

Concern has been expressed for the New York Bight apex, adjacent to New York Harbor, regarding the environmental impact of ocean disposal of dredged material generated during routine harbor

maintenance. Contaminants such as chlorinated hydrocarbons, toxic metals and petroleum hydrocarbons have been detected in New York Harbor's dredged material as well as the six-mile dumpsite. A bioaccumulation monitoring study was conducted using blue mussels transplanted to eight New York Bight locations. Pooled tissue samples were analyzed for total concentrations of mercury, cadmium, lead, DDT, polychlorinated biphenyls (PCBs), and No. 2 fuel oil. Stations were sampled weekly for one month, after which bi-monthly mussel collections were conducted. Some stations were damaged due to storm and human activities. Throughout the study, DDT concentrations in mussels generally remained below analytical detection for all stations. Although the three metals (mercury, cadmium and lead), PCB, and the fuel oil were consistently detected at all stations, none of these contaminants were detected in excess of existing regulatory guidelines. Bioaccumulation of mercury and cadmium was significantly greater for animals exposed at the dredged material dumpside than at both immediate and distant reference stations. Higher levels of lead were also found near the dumpsite. Although net PCB bioaccumulation occurred at all stations, the pattern of uptake was erratic over time. No. 2 fuel oil accumulation had relatively minimal uptake during initial exposure, followed by a dramatic increase in early spring. (Garrison-Omniplan)

Descriptors: *Detergents, *Water pollution effects, Snails, Aquatic life, Calcium, Mollusks, Adsorption.

Synthetic detergents are among the major pollutants affecting aquatic biota. A biostatic assay method involving Ca-45 uptake into shells and tissues of snails in 72 hr was developed in efforts to follow the effect of detergent-polluted water on ecosystems. A marked decrease in the Ca-45 uptake by shells (34.43%) and tissues (37.72%) of linear alkyl benzene sulfonate-exposed animals was noted. No change in Ca-45 uptake was observed in dead shells, thereby excluding the possibiliy of passive exchange. Detergent may possibly affect the active exchange of calcium by inhibiting the activity to carbonic anhydrase and reducing the rate of shell formation. (Baker-IVI)

EFFECTS OF TWO HERBICIDES ON SELECTED AQUATIC BACTERIA,
Illinois Natural History Survey, Champaign.
J. Beckmann, P. Tazik, and R. Gorden.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 2, p 243-250, February, 1984. 1 Fig, 1 Tab, 21 Ref.

Descriptors: *Herbicides, *Water pollution effects, *Bacteria, Aquatic life, Fate of pollutants, Simazine, Endothall.

Herbicide applications in aquatic systems may affect bacterial populations directly by either inhibiting or stimulating the metabolism of specific functional groups or of the entire community. The effects of simazine and endothall on bacterial populations in aquatic ecosystems were evaluated. Effects of endothall and simazine on growth and respiration of common bacterial isolates obtained from aquatic ecosystems were also studied. Neither herbicide had a significant effect on total bacterial numbers present in the water column, present in sediments, or attached to macrophytes. Endothall at 5 ppm apparently slightly inhibited the respiration rate of Micrococcus sp., slightly stimulated respiration of Pseudomonas vesicularis, and had no obvious effect on the respiration rate of Bacillus sp. Simazine at 3 ppm increased the respiratory activity of four isolates. (Baker-IVI)

ENVIRONMENTAL ASPECTS OF THE USE OF NTA AS A DETERGENT BUILDER,
Imperial Coll. of Science and Technology, London (England). Dept. of Civil Engineering.
R. Perry, P. W. W. Kirk, T. Stephenson, and J. N. Lester.
Water Research, Vol. 18, No. 3, p 255-276, 1984. 10 Fig, 185 Ref.

Descriptors: *Nitrilotriacetic acid, *Detergents, *Heavy metals, Wastewater treatment, Biodegradation, Water pollution sources, Metal speciation, Sludge disposal, Water pollution sources.

The behavior, fate and significance of the detergent builder nitrilotriacetic acid (NTA) was reviewed with particular emphasis on the removal of NTA during wastewater treatment and the effects of NTA on heavy metal solubility both during treatment and in the receiving environment. NTA removal during secondary biological treatment is subject to considerable variation, both temporal and between works as a result of changes in NTA load, temperature, water hardness and treatment process parameters. Due to such variability, effluent NTA concentrations may be sufficient to mobilize heavy metals resulting in metal contamination of receiving waters and potable waters, particularly in areas of low effluent dilution and high water re-use. Removal of NTA during primary sedimentation and septic tank treatment occurs primarily by adsorption to the sludge solids while removal in anaerobic sludge digestion is subject to operational characteristics of the treatment works. Disposal of NTA contaminated sludge to land may contaminate groundwaters and affect heavy metal speciation, while the disposal of contaminated sludge or sewage to the sea may result in toxic algal blooms, in addition to the effects on metal speciation. EXCHANGE OF OXYGEN AND CARBON DIOXIDE ACROSS THE WATER SURFACE DURING ALGAL BLOOMS IN A POND,
Tokyo Univ. (Japan). Dept. of Chemical Engineering.
H. Nishimura, M. Nakajima, and M. Kumagai.
Water Research, Vol. 18, No. 3, p 345-350, 1984. 8 Fig, 18 Ref.

Descriptors: *Eutrophication, *Oxygen, *Carbon dioxide, Ponds, Algal growth, Algae, Gas exchange, Chlorophyll-a.

During algal blooms, total inorganic carbon (TCO2) is rapidly consumed through high photosynthetic activity of algae, and is often depleted to a trace in surface waters. Under these conditions, TCO2 may limit the algal growth rate. Measurements were taken of oxygen and total carbon dioxide, pH and chlorophyll-a as they related to the exchange of oxygen and carbon dioxide across the water surface of a pond during algal blooms. Light and dark bottles were also used to study the production and consumption rates of oxygen due to biological activity. Algal blooms occurred twice during the 22 day study period. The trajectory on the phase plane showing the time changes in concentration of oxygen and total carbon dioxide made a clockwise, converging loop. To distinguish the role of gas exchange from that of deposits, a new concept and quantity called total oxygen (TO2) is proposed. TO2 is the sum of the concentrations of O2 and TCO2. The total amount of TO2 decreased during the production period and increased during the decomposition period. This was due to the difference between O2 and TCO2. During the production period, 60% of produced O2 was lost to the atmosphere and 20% of consumed TCO2 was supplied from the atmosphere. During the decomposition period, 80% of consumed O2 was supplied, and 35% of produced TCO2 was lost. (Baker-IVI)

UPTAKE, DISTRIBUTION, METABOLISM AND CLEARANCE OF CHLORDECONE BY CHANNEL CATFISH (ICTALURUS PUNCTATUS),
Virginia Inst. of Marine Science, Gloucester Point.
P. A. van Veld, M. E. Bender, and M. H. Roberts, Jr.
Aquatic Toxicology, Vol. 5, No. 1, p 33-49, February, 1984. 2 Fig, 6 Tab, 38 Ref.

Descriptors: *Pesticides, *Water pollution effects, *Catfish, Fish, Chlordecone, Kepone, Adsorption, Accumulation, Metabolism, Path of pollutants.

Potential health and environmental hazard have arisen for the discharge of chlordecone (Kepone) into the upper tidal portion of the James River. Channel catfish were exposed to a C-14 labeled chlordecone-contaminated diet for 90 days, followed by a chlordecone-free diet for 30 days. Uptake and clearance rate constants were 0.237 and 0.080/day, respectively. The half-life of chlordecone in the fish was 8.7 days. The dietary accumulation factor defined as the equilibrium concentration of pesticide in fish/daily dietary dosage level was 3.0. The blood and brain contained the highest concentrations of chlordecone. Lowest concentrations were in the mesenteric adipose and carcass. Chlordecone may be eliminated with bile via the intestinal contents. It may also be excreted across the gills and sloughed off with epidermal mucus. Urinary excretion is negligible. The catfish can reduce chlordecone to chlordecone alcohol. Metabolic transformation of chlordecone by aquatic organisms has not previously been reported. Enzymatic digestion of bile with beta-glucuronidase did not significantly affect the recovery of chlordecone or chlordecone alcohol. (Baker-IVI)

COMMUNITY WATERBORNE GASTROENTERITIS OUTBREAK: EVIDENCE FOR ROTAVIRUS AS THE AGENT,
Colorado Dept. of Health, Denver. Disease Control and Epidemiology Div.
R. S. Hopkins, G. B. Gaspard, F. P. Williams, Jr., R. J. Karlin, and G. Cukor.
American Journal of Public Health, Vol. 74, No. 3, p 263-265, March, 1984. 1 Tab, 16 Ref. EPA contract CR-80880101.

Descriptors: *Public health, *Drinking water, *Water quality control, *Gastroenteritis, *Rotaviruses, Chlorination, Disinfection, Wastewater, Water pollution effects, Viruses, Eagle-Vail, Avon, Colorado.

A community waterborne nonbacterial gastroenteritis outbreak occurred in Eagle-Vail and Avon, Colorado in March of 1981. Eagle-Vail and Avon shared a common water supply and distribution system. Illness was statistically associated with water consumption. Five of seven persons associated with the outbreak were infected with rotavirus. Bacterial pathogens, Giardia lambia, and Norwalk virus were excluded as possible agents. Four coincident physical factors probably contributed to the outbreak: a sewage treatment plant was discharging sludge solids into Gore Creek, upstream from the water intake for the Eagle-Vail water treatment plant; there was no chemical or physical pretreatment of water prior to filtration at the plant; severely channeled filter beds were found in the water treatment plant; and the Eagle-Vail chlorinator failed on March 4, 1981. This chlorinator was the only effective barrier between the toilets of Vail and the watertaps of Eagle-Vail and Avon. (Baker-IVI)

EVALUATION OF CHANGES IN A LARGE OLIGOTROPHIC WILDERNESS PARK LAKE EXPOSED TO MINE TAILING EFFLUENT FOR 14 YEARS: THE PHYTOPLANKTON,

Victoria Univ. (British Columbia). Dept. of Biology.
A. Austin, and N. Munteanu.

Environmental Pollution (Series A), Vol. 33, No. 1, p 39-62, 1984. 4 Fig, 5 Tab, 38 Ref.

Descriptors: *Water pollution effects, *Mine wastes, *Phytoplankton, Oligtrophic lakes, Buttle Lake, Upper Campbell Lake, Mercury, Zinc, Copper, Cadmium, Lead, Diatoms, Desmids, Upper Quinsam Lake, British Columbia.

Buttle Lake lies at the head of the extensive Campbell River watershed. Much of the drainage basin is located within the boundaries of Strathcona Provincial Wilderness Park. The lake connects by a narrow passage with Upper Campbell Lake which feeds into Lower Campbell Lake. Both Upper and Lower Campbell Lakes were formed from a river system by the construction of three dams. Mine tailings from a concentrator have been fed into Buttle Lake since 1967 via a submerged outfall. Data from phytoplankton samples collected in 1966, 1967, and 1968 were compared with data collected in 1980 and 1981. While the nutrient levels do not appear responsible, the levels of heavy metal concentrations have increased and reached values substantially above background levels in a control lake, Upper Quinsam Lake. Organisms intolerant of heavy metals, including several diatom and desmid species, have either disappeared or become extremely rare. Increases in abundance of Navicula cryptocephala, Synedra acus, S. ulna, Cyclotella bodanica and C. glomerata have been noted as these species are tolerant of the metal concentrations. These changes have resulted in a decrease in species diversity and species number. (Baker-IVI)

EFFECTS OF TRICHLOROETHYLENE ON THE POPULATION DYNAMICS OF PHYTO- AND ZOOPLANKTON IN COMPARTMENTS OF A NATURAL POND,

Gesellschaft fuer Strahlen- und Umweltforschung m.b.H. Muenchen, Neuherberg (Germany, F.R.). Inst. fuer Okologische Chemie.
J. P. Lay, W. Schauerte, and W. Klein.

Environmental Pollution (Series A), Vol. 33, No. 1, p 75-91, 1984. 6 Fig, 2 Tab, 21 Ref. Commission of the European Communities Contract No. 187-77-1 ENV D.

Descriptors: *Zooplankton, *Population dynamics, *Water pollution effects, Ponds, Trichloroethylene, Organic compounds, Trophic levels.

Single doses (110 and 25 mg/liter) of trichloroethylene (Tri) were applied in replicates to the water of compartments of a natural pond. In comparison to two control compartments and the surrounding water, the disappearance rates of Tri and the effects on the biota were measured. Disappearance rates of Tri from the aquatic phase were equal for both chemical concentrations and were determined at a half-life of 2.7 days. Both initial concentrations of Tri were highly toxic to Daphnia and caused a decrease (low dose) or elimination (high dose) of this species shortly after application. Following Tri application the phytoplankton community changes from high to low diversity. Relative abundance and the absolute number of all phytoplankton individuals counted increased, mostly in the high-dosed compartments. Autotrophic phytoplankton species were eliminated in part, heterotrophic ones significantly increased. Physicochemical properties of the water were not significantly influenced by the treatment. RECOVERY OF DDT, KEPONE, AND PERMETHRIN ADDED TO SOIL AND SEDIMENT SUSPENSIONS INCUBATED UNDER CONTROLLED REDOX POTENTIAL AND PH CONDITIONS,

Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
R. P. Gambrell, C. N. Reddy, V. Collard, G. Green, and W. H. Patrick, Jr.

Journal Water Pollution Control Federation, Vol. 56, No. 2, p 174-182, February, 1984. 8 Fig, 2 Tab, 15 Ref. EPA Grant R804940-01-1.

Descriptors: *Pesticides, *Fate of pollutants, *Environmental effects, Permethrin, DDT, Kepone, Chemical reactions, Organic compounds.

The persistence and fate of organic pesticides and therefore their environmental impact differs widely under various physicochemical conditions. Permethrin can be strongly affected by physicochemical conditions of the environment during the course of a few weeks to a few months. Strongly reducing conditions characteristic of sediments enhance the persistence of Permethrin. The effects of pH on recovery of DDT from amended sediment material were negligible at each of the four redox potential levels studied. Redox potential treatments, however, greatly affected DDT recovery. At all redox potentials used there was no evidence of any reduction in Kepone levels during the 52 day study. At pH levels of 5.0 and 8.0 there was some evidence of a decrease in Kepone concentrations toward the end of incubation (51 and 70 days, respectively), but any degradation, if it occurred, was masked by experimental variability encountered in the incubation conducted at these two pH levels. At all pH levels, there was no good indication that oxidation-reduction conditions affected Kepone degradation. Strongly reduced environs of many sensitive benthic species favor some increase in the persistence of residues that may adversely affect these populations. (Baker-IVI)

MEASUREMENT OF BENTHAL OXYGEN DEMAND IN THE HOUSTON SHIP CHANNEL,

Espey, Huston and Associates, Inc., Austin, TX.
G. H. Ward, Jr.

Journal Water Pollution Control Federation, Vol. 56, No. 2, p 183-191, February, 1984. 5 Fig, 1 Tab, 24 Ref.

Descriptors: *Benthos, *Oxygen demand, *Harbors, *Houston Ship Channel, Texas, Channels, Respirometer, San Jacinto River, Turning Basin, Temperature effects, Water pollution effects.

The Houston Ship Canal is a dredged canal from the entrance of Galveston Bay to the Port of Houston within the San Jacinto River System across the bay. The upper reach is highly developed, and includes several municipal treatment plants and the bulk of the Houston petrochemical complex. There is a substantial wastewater return in this reach and it is a region of consistently poor water quality. Respirometers developed in this study seem to be a useful method for direct measurement of the potential oxygen demand of Houston Ship Channel sediments. The homogenate BOD6 (HBOD6) test appears to be a satisfactory, economical indicator of large scale, intensive surveys of benthal oxygen demand. The potential benthal oxygen demand varied from 0.7 to 4.2 g/sq m/day, generally increasing with distance up the channel from the San Jacinto confluence toward the Turning Basin. Nitrification did not play any role in the oxygen depletion of samples in this study. The addition of methylene blue produced no systematic alteration in benthal oxygen demand. (Baker-IVI)

MERCURY AND POLYCHLORINATED BIPHENYLS IN STRIPED BASS (MORONE SAXATILIS) FROM TWO NOVA SCOTIA RIVERS,

Department of Fisheries and Oceans, St. Andrews (New Brunswick).
S. Ray, B. M. Jessop, J. Coffin, and D. A. Swetnam.

Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 15-23, January, 1984. 1 Fig, 5 Tab, 28 Ref.

Descriptors: *Water pollution effects, *Bass, *Annapolis River, *Shubenacadie River, *Nova Scotia, *Mercury, *Polychlorinated biphenyls, Organic compounds, Heavy metals, Toxicity, Fisheries.

The striped bass fishery in the Annapolis and Shubenacadie Rivers of Nova Scotia is of sport and commercial importance. In recent years, the striped bass have not reproduced successfully in the Annapolis River, whereas they have no recruitment problem in Shubenacadie River. Striped bass were obtained from the angling fishery in the Annapolis River and from both angling and commercial fisheries of the Shubenacadie River in Nova Scotia, Canada. Analyses were performed for mercury content in four tissues and for PCBs in two tissues. The average mercury concentrations in the muscle, liver, kidney, and gonad of 3.9 kg fish from the Annapolis River were 0.77, 0.79, 0.26, and 0.07 micrograms/g, respectively. Corresponding values for the 1.5 kg fish from the Shubenacadie River were 0.51, 0.27, 0.24, and 0.06 micrograms/g. PCB concentrations in the muscle tissues of fish from Annapolis and Shubenacadie Rivers are 0.02 and 0.01 micrograms/g, respectively, while the concentrations in gonads are 1.4 and 0.04 micrograms/g. The observed lack of stock recruitment of striped bass in the Annapolis River may be related to high PCB concentrations in the gonad tissues. (Baker-IVI)

VARIATIONS IN SURFACE WATER PH WITH CHANGES IN SULPHUR DEPOSITION,

Sentralinstitutt for Industriell Forskning, Oslo (Norway).
H. M. Seip, and S. Rustad.

Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 217-223, January, 1984. 2 Fig, 2 Tab, 7 Ref.

Descriptors: *Acidity, *Lakes, *Acid rain, *Hydrogen ion concentration, Precipitation, Sulfates, Sulfur, Water pollution sources, Aluminum, Birkenes catchment, Norway.

The effects on surface water acidity brought about by a doubling of the sulfate concentration in runoff are considered. A very simple two reservoir hydrological model was used in the calculations. The upper reservoir supplies quickflow and can be thought of as water mainly in contact with upper soil horizons. The lower reservoir provides the base flow. It was found to be a useful approximation for the Birkenes catchment in southernmost Norway, but this is not necessarily true for most other catchments. A possible refinement of this approach would call for inclusion of other substances. Aluminum species and organic acids would give increased buffering intensities. Doubling of the sulfate concentrations in the runoff in this study may in some cases give pH decreases of 0.7 to 1.0 units or even more, from about 6 to about 5, assuming no changes in soil properties, such as base saturation, occurred. SYNERGISTIC EFFECTS OF HEAVY METAL POLLUTANTS ON SENESCENCE IN SUBMERGED AQUATIC PLANTS,

Burdwan Univ. (India). Plant Physiology and Biochemistry Lab.
S. Jana, and M. A. Choudhuri.

Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 351-357, January, 1984. 4 Tab, 6 Ref.

Descriptors: *Water pollution effects, *Heavy metals, *Plant growth, Mercuric chloride, Lead acetate, Cadmium chloride, Cupric sulfate, Aquatic plants, Potamogeton, Vallisneria, Hydrilla, Bioindicators.

Water pollution by industrial wastes containing compounds of various heavy metal pollutants disturbs the vegetation in aquatic habitats. The sensitivity to a specific combination of toxic concentrations of heavy metal pollutants may differ for different species and it may be possible to exploit the differences in sensitivity to select indicator species for water pollution. The effects of many combinations of toxic concentrations of heavy metal pollutants, viz., mercuric chloride, lead acetate, cadmium chloride and cupric sulfate, on the

senescence of isolated mature leaves of submerged aquatic plants, Potamogeton pectinatus L., Vallisneria spiralis L., and Hydrilla verticillata (L.f.) Royle were studied. All of the combinations of heavy metal pollutants caused senescence in all three species by decreasing chlorophyll, DNA, RNA, protein and dry wt, and increasing free amino acid, tissue permeability, the activities of protease and RNase, and the ratio of acid to alkaline pyrophosphatase activity over control values. The effects were highest in Potamogeton and lowest in Hydrilla. The degree of senescence in the three submerged plants by combinations of toxic concentrations of heavy metal pollutants is much higher due to synergism than that by individual heavy metal pollutants. ALTERATIONS IN CARBON FIXATION DURING POWER PLANT ENTRAINMENT OF ESTUARINE PHYTOPLANKTON,
Academy of Natural Sciences of Philadelphia, Benedict, MD. Benedict Estuarine Research Lab.
K. G. Sellner, M. E. Kachur, and L. Lyons.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 359-374, January, 1984. 10 Fig, 5 Tab, 18 Ref.

Descriptors: *Powerplants, *Phytoplankton, *Carbon fixation, *Entrainment, Phytoplankton population, Population densities, Dinoflagellates, Diatoms, Carbon, Estuarine environment, Estuaries.

The entrainment of estuarine waters in the cooling units of the Calvert Cliffs Nuclear Power Plant resulted in elevated productivities in June and reductions in C fixation rates for the total phytoplankton assemblages in July through September. In the latter 3 months, the passage of Bay water through the plant was accompanied by a decline in the photosynthetic activity of the microflagellate, Cryptomonas acuta. Phytosynthetic rates of the diatom Cyclotella and Thalassionema and the dinoflagellate Prorocentrum were not significantly altered by passage through the power plant. Assuming other representatives of each phyla respond in a similar manner, depressed phytoplankton productivity in entrained Bay waters would be expected when flagellates (as unidentified microflagellates and cryptophytes) dominate the phytoplankton assemblage and the entrainment temperature exceeds 30 degrees C. ENVIRONMENTAL FECAL POLLUTION AND CONCENTRATION POWER OF THE CLAM CHAMELEA GALLINA,
Istituto Superiore di Sanita, Rome (Italy).
L. Volterra, G. Piccininno, E. Palliola, F. A. Aulicino, and M. Gianfranceschi.
Water, Air, and Soil Pollution, Vol. 21, No. 1-4, p 415-424, January, 1984. 4 Tab, 23 Ref.

Descriptors: *Water pollution effects, *Clams, *Bacteria, Microorganisms, Sewage bacteria, Wastewater, Italy.

Hygienic conditions of a commercially important clam, Chamelea (Venus) gallina, widely distributed along the Italian coasts were examined, with particular interest paid to whether these clams, inside their valves, accumulate microorganisms and pathogens which are present in marine sediments, directly carried into the sea by sewers, indirectly by rivers and canals. The habitat of C. gallinas is the sediment of shallow waters, from 4 to 6 m. In Italy, these depths may be located at about 200 up to 1000 m from the coastline. Five clam beds have been simultaneously surveyed, collecting samples of water, sediment and mollusks. Four extensive clam banks in the Adriatic sea (Chioggia, Goro, Rimini, Cupra Marittima) and a bank recently discovered in the Tyrrhenian sea at Caprolace were sampled. Total coliforms, fecal coliforms, and fecal streptococci have been analyzed. Results indicate that this shellfish does not seem to accumulate enteric bacteria in spite of the microbial contamination of water and sediment. (Baker-IVI)

EFFECTS OF VOLCANIC ASH ON THE BENTHIC ENVIRONMENT OF A MOUNTAIN STREAM, NORTHERN IDAHO,
Geological Survey, Boise, ID. Water Resources Div.
S. A. Frenzel.
Available from the Ofss, USGS, Lakewood, CO 80225, Price: $4.75 in paper copy, $3.50 in microfiche. USGS Water-Resources Investigation Reports 82-4106, Jan. 1983. 32 p, 6 Fig, 6 Tab, 26 Ref.

Descriptors: *Stream, *Environment, Habitats, *Water quality, Benthos, *Sediments, *Idaho, Big Creek, Gedney Creek, Volcanic ash.

The May 18, 1980, eruption of Mount St. Helens deposited about 15 millimeters of volcanic ash on the Big Creek basin in northern Idaho. Much of the uncompacted ash remained on hillsides a year after the eruption. Physical and chemical analyses of water samples from Big Creek collected from December 1980 to December 1981 showed no anomalies attributable to ash. Qualitative collections showed benthic invertebrates to be abundant and diverse in Big Creek. Experiments conducted in an unimpacted mountain stream revealed a small quantity of volcanic ash may be beneficial not detrimental to invertebrate communities. Benthic invertebrates were most abundant on ash-covered artificial substrates, with detritovores dominating the communities on all substrates. (USGS)

POLLUTED GROUNDWATER CLEARLY A PROBLEM, BUT FEW AGREE ON EXTENT OR SOLUTION,
L. Mosher.
National Journal, Vol. 16, No. 5, p 223-225, February, 1984.

Descriptors: *Groundwater pollution, *Federal jurisdiction, Environmental Protection Agency, Management, Political aspects, Water pollution sources, Land use, Waste dumps.

Contamination threatens the underground water supply of the United States. A chief source of the pollution is land-related, being the runoff from farms and cities, which contains a rich brew of synthetic organic toxic chemicals, most of which do not break down in the ground. Regulating land use is primarily a state responsibility that the federal government cannot directly interfere with. After a change in leadership at the EPA last May, a revision of that department's approach to groundwater pollution control was expected. Under a new plan, states are given the primary responsibility to protect groundwater, but the agency would attempt to use the 1976 Toxic Substances Control Act to regulate underground storage tanks, which it considers a major contamination course. Three classes of groundwater would be distinguished, each with its own level of protection required. Some have expressed disappointment with the new plan, indicating it is little more than a public relations move. One impoundment study reportedly found 180,973 waste ponds around the country, almost half of which were over aquifers, and only 30% of which have protective liners. (Baker-IVI)

FATE AND EFFECTS OF ATRAZINE IN SMALL AQUATIC MICROCOSMS,
Environmental Research Lab., Athens, GA.
D. L. Brockway, P. D. Smith, and F. E. Stancil.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 3, p 345-353, March, 1984. 4 Fig, 10 Ref.

Descriptors: *Water pollution effects, *Herbicides, Atrazine, Aquatic life, Organic compounds, Agricultural chemicals, Fate of pollutants.

The objectives of this study were to determine the fate and effects of atrazine on small laboratory microcosms, to evaluate the resilience of the systems after removal of the atrazine, and to compare the responses of different types of test systems to the herbicide. This study was carried out with mixed biota communities in either continuous-flow aquaria or static beakers. Atrazine concentrations of 0, 0.5, 5, and 50 micro g/l were introduced into the continuous-flow aquaria. The experiments in the static beakers tested concentrations of 0 to 5000 micro g/l. The degradation and sorption of atrazine was very low in aquatic systems. Atrazine had a negative impact on primary producers at and above a concentration of 50 micrograms/L and possibly below. These effects are expressed best in oxygen production and dissolved nitrate in the systems. The small static systems are able to furnish results similar to those of larger more complex systems, particularly for quick response parameters. (Baker-IVI)

EFFECTS OF CRUDE DUBAI OIL ON SALMO GAIRDNERI RICH. AND CARASSIUS AURATUS L.,
Milan Univ. (Italy). Sezione di Ecologia.
M. C. Ramusino, R. Dellavedova, and D. Zanzottera.
Bulletin of Environmental Contamination and Toxicology, Vol. 32, No. 3, p 368-376, March, 1984. 5 Fig, 2 Tab, 6 Ref.

Descriptors: *Water pollution effects, *Oil spills, *Fish, Toxicity, Po River, Italy, Dubai oil, Organic compounds, Carassius, Salmo.

About 663 tons of crude Dubai oil poured into the river Po, the largest Italian river in 1980 as a result of a burst oil pipeline. Laboratory tests were carried out to identify the lethal concentrations and the concentration threshold value (below which mortality does not occur) for crude Dubai oil. Tests on Carassius auratus, treated with Dubai crude undiluted, resulted in a 48 hr LC50 of 19.89 ml/L. In tests with the water soluble fraction (WSF) of crude Dubai, an initial phase of acute toxicity was present during which mortalities occurred. However, for those animals who survived this initial phase, complete recovery was apparent. This suggests the presence of a fairly toxic volatile component which causes the acute initial effects and then evaporates. Tests using Salmo gairdneri indicate that this organism is extremely sensitive to this form of pollution. Even so, differences were evident in the response to crude oil and to its WSF. (Baker-IVI)

LEAF LITTER BREAKDOWN IN STREAMS RECEIVING TREATED AND UNTREATED METAL MINE DRAINAGE,
Colorado State Univ., Fort Collins. Dept. of Zoology and Entomology.
L. J. Gray, and J. V. Ward.
Environment International, Vol. 9, No. 2, p 135-138, 1983. 2 Fig, 14 Ref.

Descriptors: *Litter, *Mine drainage, Organic matter, Streams, Colorado, Iron, Metals, Decomposition, Water pollution effects.

Because of its importance in the flow of energy in streams, leaf decomposition provides an ecosystem-level measure of pollution effects. Rates of alder leaf decomposition were used as a measure of effects of untreated and treated acid mine drainge on two Colorado mountain streams. The two study streams were Kerber Creek, a third-order tributary of San Luis Creek, and Coal Creek, a third-order tributary of the Slate River. Untreated mine effluents had low pH and high concentrations of metals, particularly iron. Deposition of ferric hydroxide on leaf surfaces inhibited colonization by decomposers, such as fungi and aquatic insects, and thus little leaf breakdown occurred. Treated effluents had improved water quality (basic pH, low metal concentrations), but suspended flocs released by the treatment process buried leaves and reduced consumer activity. The rate of leaf breakdown was not significantly different from the rate with untreated effluents. Thus improvement in water quality alone was insufficient to restore this important pathway of energy flow in headwater streams. (Baker-IVI)

TCDD DISTRIBUTION IN THE SPRING RIVER, SOUTHWESTERN MISSOURI,
Environmental Protection Agency, Kansas City, MO. Region VII.
R. D. Kleopfer, and J. Zirschky.
Environment International, Vol. 9, No. 4, p 249-253, 1983. 1 Fig, 1 Tab, 13 Ref.

Descriptors: *Water pollution effects, *Spring River, *Missouri, *Fish, *Sediments, *TCDD, Dioxins, Biological magnification, Industrial wastes, Waste disposal.

The waste management practices of a chemical company (no longer in business) created several disposal sites containing materials contaminated with TCDD, 2,3,7,8-tetrachlorodibenzo-p-dioxin. The facility manufactured hexachlorophene from tetrachlorobenzene with 2,4,5-trichlorophenol (TCP) produced as an intermediate. TCDD was formed as an unwanted trace contaminant of the TCP. A sampling survey of the Spring River, which drains the disposal sites, was conducted to determine if TCDD contamination had occurred. Levels detected in the upper reaches of the river tend to indicate that the contamination of the river has resulted from the waste management practices of the former company. Fish contamination above the point in the stream where pollution could enter the water could be explained by migration of the fishes. Two dams near Carthage, MO were expected to prevent sediment migration beyond that point and thus limit fish contamination to areas upstream of the dams. Contaminated fish were found for a distance of at least 21 miles beyond the dams, which were not physical barriers to fish movement in either direction. Bioconcentration of extremely low levels of TCDD from the aqueous phase may also explain the extent of the contamination. The detection limits were not sufficient to determine the sediment TCDD concentration in the river. TCDD was only found in sediments immediately downstream of the former manufacturing facility at 12 ng/kg. (Baker-IVI)

Growth represents a complex response to a variety of environmental factors. Bioenergetics modeling is an efficient means of evaluating the relative importance of these variables. A bioenergetics model for largemouth bass (Micropterus salmoides) simulates growth as a function of body size, temperature, activity and consumption level . The model is applied to bass in Par Pond, South Carolina, a reservoir receiving heated effluent, to investigate seasonal changes in condition factor. Previous authors have suggested that these changes occur due to bioenergetic constraints, primarily the effects of heated effluent on metabolic rate. Model simulations were used to evaluate the hypotheses that seasonal changes in condition factor were caused by the heated effluent, seasonally variable activity, seasonally variable consumption, or reproductive costs. Results indicate that temperature is not directly responsible for the seasonal changes in condition factor. Bass moderate the influence of the heated effluent via behavioral thermoregulation. Activity is not a major factor, and spawning weight-loss can account for only a small portion of the observed variation. However, the pattern of seasonal changes in body condition may be adequately explained by seasonal variations in consumption. The patterns of consumption rate and/or prey availability suggested by model simulations represent testable hypotheses. (Murphy-IVI)

ACIDIC PRECIPITATION EFFECTS ON CROPS: A REVIEW AND ANALYSIS OF RESEARCH,
Argonne National Lab., IL.
P. M. Irving.
Journal of Environmental Quality, Vol. 12, No. 4, p 442-453, 1983. 2 Fig, 2 Tab, 34 Ref.

Descriptors: *Acid rain, *Literature review, Environmental effects, Crop yield, Air pollution effects, Air pollution, Deposition, Simulated rain, Acidic deposition.

For more than a century it has been known that vegetative growth is affected by the products of fossil fuel combustion. Recently, the acidic deposition phenomenon has gained increasing attention, especially when implicated as a factor responsible for economic loss. Research has been directed toward quantification of effects; however, limitations in the design of many crop studies restricts the usefulness and applicability of the results. Acidic deposition varies in a number of ways that may affect crop yield (i.e., level of acidity, amount and intensity of rain, S and N doses). The responses of these variables may be nonlinear. To allow comparisons of published acid precipitation effects research, calculations for this review were made (based on information in the literature or from personal communication) to describe the experimental conditions, the various dose parameters, and the responses in comparable units for each investigation. The majority of crop species studied in field and controlled environment experiments exhibited no effect on growth nor yield as a result of simulated acidic rain. The growth and yield of some crops, however, was negatively affected by acidic rain; others exhibited a positive response. This analysis of the current literature concludes that the effects of acidic precipitation on crops appear to be minimal and that when responses are observed, they may be positive or negative. More complex experimental designs and analyses may be necessary in order to examine and describe the possible subtle responses of agricultural systems to acidic precipitation. (Author's abstract)

EFFECTS OF ACIDITY AND ALKALINITY ON THE STABILITY OF AMIDOHYDROLASES IN FRESHWATER,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
W. T. Frankenberger, Jr., and A. L. Page.
Journal of Environmental Quality, Vol. 12, No. 4, p 459-462, 1983. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Acidic water, *Alkalinity, *Amide-N, *Enzymatic hydrolysis, L-asparaginase, L-glutaminase, Amidase, Urease, Hydrogen ion concentration, Lakes, Cycling nutrients, Organic compounds, Microbial degradation.

The influence of acidity and alkalinity on the enzymatic hydrolysis of amide-N in the aquatic system was investigated by determining the stability of L-asparaginase (EC (Enzyme Commission) 3.5.1.1.), L-glutaminase (EC 3.5.1.2.), and amidase (EC 3.5.1.4.), and urease (EC 3.5.1.5.) with respect to pH in three freshwater lakes. The water samples were first incubated at the indicated buffer pH (1-13) for 24 h; then each enzyme was assayed at its optional pH (pHopt) under standardized conditions. L-Asparaginase retained essentially 100% of its activity within the pH range of 6-7 in Lake Evans and Lake Matthews, and 5-7 in Lake Perris. L-Glutaminase was active between pH 6 and 7 in the water samples surveyed. Amidase remained completely active at pH ranges of 4-8 in Lake Evans, 4-7 in Lake Matthews, and 5-8 in Lake Perris. Urease remained active over a broad pH range of 5-9 in Lake Evans, 5-8 in Lake Matthews, and 4-8 in Lake Perris. There was a progressive loss in enzymatic activity below and above these pH ranges. The results suggest that the decline in aquatic amidohydrolase activities in relation to the pH-profile near their pHopt was caused by a reversible reaction involving the ionization or deionization of functional groups of the active center of the protein, but under highly acidic or alkaline conditions (pH < 4 to > 9) the reduced activity appears to be due to irreversible inactivation of the enzyme. (Author's abstract)

RESPONSE OF SOYBEANS TO SIMULATED ACID RAIN IN THE FIELD,
North Carolina State Univ. at Raleigh. Dept. of Plant Pathology.
A. S. Heagle, R. B. Philbeck, P. F. Brewer, and R. E. Ferrell.
Journal of Environmental Quality, Vol. 12, No. 4, p 538-543, 1983. 1 Fig, 3 Tab, 19 Ref.

Descriptors: *Ecological effects, *Soybeans, *Simulated rainfall, *Acid rain, Crop yield, Soil chemistry, Hydrogen ion concentration, Rhizobium nodulation, Nematodes.

Soybeans, Glycine max (L.) Merr, 'Davis', were grown in the field during 1979 and 1980 to determine effects of semiweekly applications of simulated rain at different acidity levels in addition to ambient rain on foliage, growth, yield, Rhizobium nodulation, soil chemistry, and soil nematode populations. Plants were exposed twice weekly to 0.74 cm (1979) or 0.85 cm (1980) of simulated rain at pH levels of 5.5, 4.0, 3.2, or 2.8 in 1979 and 5.4, 4.1, 3.2, or 2.4 in 1980. There were six 3-sq m plots (replicates) for each pH level. Simulated rain at pH 2.8 or 2.4 caused small amounts of foliar injury evident as bifacial white or tan lesions primarily on young leaves. However, plant growth, pod yield, foliar elemental content, seed protein content, seed oil content, Rhizobium nodulation of roots, and populations of parasitic nematodes were not affected. Soil analyses were performed before, midway through, and after each season. Trends toward lower soil pH, and less Ca, Mg, and K occurred with increased acidity of simulated rain. These effects were statistically significant only for soil pH, Mg, and K at treatment pH 2.4. Possible effects of ambient rain at current pH levels on agricultural soils are likely to require long-term deposition. (Murphy-IVI)

EFFECT OF FOUR TERRESTRIAL HERBICIDES ON THE PRODUCTIVITY OF ARTIFICIAL STREAM ALGAL COMMUNITIES,
Texas A and M Univ., College Station. Dept. of Soil and Crop Sciences.
R. J. Kosinski, and M. G. Merkle.
Journal of Environmental Quality, Vol. 13, No. 1, p 75-82, 1984. 4 Fig, 2 Tab, 54 Ref. EPA grant 807978-01.

Descriptors: *Ecological effects, *Herbicides, *Algae, *Artificial streams, Streams, Atrazine, Trifluralin, Monosodium methanearsonate, Paraquat, Water pollution, Primary productivity.

Artificial streams containing algal communities derived from a spring and an agriculturally impacted stream were used to assess the effect of 0.1, 1, and 10 mg/kg atrazine 2-chloro-4-(ethylamino)-6-(isopropylamino)-s-triazine, trifluralin (alpha, alpha, alpha-trifluoro-2,6-dinitro-N,N-dipropyl-p-toluidine), MSMA (monosodium methanearsonate), and paraquat (1,1'-dimethyl-4,4'-bipyridylium cation) on the productivity (photosynthesis and respiration) of stream algae. Algae of streams receiving runoff from agricultural lands are an obvious nontarget community. The importance of induced resistance to the herbicides was evaluated by comparing the responses of the spring and stream algae and by determining if allowing the streams to be colonized for 3 weeks in the presence of 0.01 mg/kg of the herbicide under test would modify response by selecting for a more resistant flora. Productivity was measured by open-water oxygen methods for 3 weeks before and 3 weeks after herbicide injection. The communities derived from both the spring and the stream were dominated by diatoms, and responded similarly to trifluralin, atrazine, and MSMA, but had divergent re-

sponses to paraquat. Trifluralin had no effect on productivity. Photosynthesis was significantly depressed by 1 and 10 mg/kg atrazine and by 10 mg/kg MSMA, and there were indications of a slight inhibition by 0.01 mg/kg atrazine. Paraquat at 10 mg/kg had little effect on the spring-derived communities but caused severe inhibition of the stream-derived algae. There was little evidence that exposure to 0.01 mg/kg herbicide during colonization modified the response of the algae to any of the herbicides. (Murphy-IVI)

BENTHOS OF A MARINE FLY-ASH DUMPING GROUND,
Newcastle upon Tyne Univ. (England). Dove Marine Lab.
R. N. Bamber.
Journal of the Marine Biological Association of the United Kingdom, Vol. 64, No. 1, p 211-226, February, 1984. 12 Fig, 1 Tab, 30 Ref.

Descriptors: *Water pollution effects, *Fly ash, *Benthic environment, *England, *Northumberland, *Coastal waters, Sediments, Aquatic animals, Powerplants, Industrial waste, Species diversity.

Blyth Power Station, in Northumberland, England is a 1548 MW coal-fired station complex, burning about 16,000 tons of coal per day, resulting in an annual dumping of one million tons of pulverized fuel ash (fly ash) off the adjacent coast. The benthic fauna of the fly-ash dumping ground off the coast was compared with that of the surrounding natural sediments and a designated offshore spoil ground. The silt fraction of the sediments increased as a result of continued ash dumping. The appearance of pozzolanic aggregates at the sites of greatest dumping also occurred, some 3.5 km offshore. The natural benthic macrofauna represented a typical Echinocardium-filiformis community, giving way throughout the offshore spoil ground to a Paraonis-Magelona community dominated by smaller polychaete species more tolerant of poor sediments. An anomalous community structure was evident at the stations at the center of the ash dumping. The density of the fauna was reduced at the center of the ash dumping, the worst station yielding only eight individuals in 0.2 sq m. Contours of numbers of macrofaunal individuals and species, of faunistic diversity and biomass, and of meiofaunal numbers all show a similar pattern of some depression along the spoil ground, and greater depression at the ash-dumping center. A negative correlation between faunistic parameters and ash content was confirmed by statistical analyses. Deposit-feeding species represented a lower proportion of the community at sites of high ash content. The negative correlation between faunistic diversity and ash content was statistically significant over an area of 43 sq km around the center of the dumping. The faunistic impoverishment is considered to be a response to the dumping. (Baker-IVI)

24-H CHANGES IN CHLOROPHYLL CONTENT OF PHYTOPLANKTON OF LAKE JELONEK, AS COMPARED WITH THE PHYSICAL AND CHEMICAL PROPERTIES OF WATER,
Poznan Technical Univ. (Poland). Inst of Environmental Engineering.
J. Panczakowa, and T. Szyszka.
Polskie Archiwum Hydrobiologii, Vol. 30, No. 3, p 207-227, 1983. 11 Fig, 3 Tab, 16 Ref.

Descriptors: *Chlorophyll, *Phytoplankton, *Lake Jelonek, *Poland, Phosphorus, Nitrogen, Nutrients, Eutrophication, Algal growth, Dissolved oxygen, Carbonates, Hydrogen ion concentration, Aphanizonmenon, Volvox, Melosira.

Measurements were taken in 1979 in the strongly eutrophic polymictic Lake Jelonek of 24-hr changes in the chlorophyll concentration, quality and quantity of phytoplankton and the chemical composition of seston as compared with the physical and chemical properties of water. Three different developmental phases of Aphanizomenon flos-aquae were studied. In June during bloom dying, in addition to Aphanizomenon flos-aquae, Volvox aureus was present, though in small number. In July, during a subsequent increase in the population of Aphanizomenon flos-aquae, relatively large numbers of Melosira granulata occurred. In August the Aphanizomenon flos-aquae predominated. In June, during the dying of the blue-green algae bloom, concentrations of dissolved oxygen and carbonate as well as the pH of water steadily decreased. The chlorophyll content continually fluctuated. In July and August, the chlorophyll content was greatest during the day. In the period of dominance of one species, the numbers of phytoplankton organisms, chlorophyll content, dissolved oxygen concentration and BOD-5 were all evidently related. Phosphorus and nitrogen showed no clear-cut 24-hr changes. (Baker-IVI)

ACTIVITY OF BENZO(A)PYRENE MONOOXYGENASE IN FISH FROM THE SAVA RIVER, YUGOSLAVIA: CORRELATION WITH POLLUTION,
Institut Rudjer Boskovic, Zagreb (Yugoslavia).
N. Kezic, S. Britvic, M. Protic, J. E. Simmons, and M. Rijavec.
The Science of the Total Environment, Vol. 27, No. 1, p 59-69, March, 1983. 1 Fig, 7 Tab, 24 Ref.

Descriptors: *Effects of pollution, *Fish, *Sava River, *Yugoslavia, Benzo(a)pyrene, Enzymes, Benzo(a)pyrene monooxygenase, Organic compounds.

Benzo(a)pyrene monooxygenase (BaPMO) activity in non-migratory fish from a given river segment is highly correlated to the recent pollution history of that part of the river. The enzyme activity level can serve as a relevant measure for the harmful pollutant potential in aquatic ecosystems. Caged experimental fish exposed for about 10 days in river segments show BaPMO activity changes with the same predictive validity as that of the natural population. The dependence of the BaPMO activities from different river segments on the degree of pollution is demonstrated. Measurement of liver BaPMO activities in natural fish populations could be used for detecting the presence, and estimating the quantity of xenobiotics in water. (Baker-IVI)

MUTAGENIC AND CLASTOGENIC EFFECTS OF ORGANIC EXTRACTS FROM THE ATHENIAN DRINKING WATER,
National Hellenic Research Foundation, Athens (Greece). Biological Research Center.
K. Athanasiou, and S. A. Kyrtopoulos.
The Science of the Total Environment, Vol. 27, No. 2/3, p 113-120, 1983. 1 Fig, 3 Tab, 23 Ref
Greek Agency for Scientific Research and Technology grants No. 80045 and 80018.

Descriptors: *Organic compounds, *Drinking water, *Athens, *Greece, *Mutagens, *Clastogens, Chlorination, Agriculture, Public health, Toxicity.

Organic extracts of chorinated drinking water collected from the water distribution system of Athens, Greece, were tested in parallel for their ability to cause mutations in the Salmonella His(+) reversion system and sister chromatid exchanges (SCE) and chromosomal aberrations in CHO cells. The Athens water distribution system supplies a population of more than 3 million people. Water is received into the system from the artificial lake of Marathon. This lake collects the waters of a river (Mornos) located at a distance of 200 km northwest of Athens by means of a canal, and those of the natural lake of Heliki, 100 km north of Athens, in the middle of one of the main cultivated areas of Greece. The extracts induced His(+) revertants in frequencies similar to those detected previously with drinking water extracts from other areas around the world. Organic samples from surface drinking water induced SCE and chromatid type abnormalities in CHO cell cultures, while samples collected from ground drinking water did not. It is possible that the high percentage of mutagens detected in this study results from the chlorination of constituents derived from agricultural runoff. (Baker-IVI)

GROWTH, FECUNDITY AND MORTALITY OF BREAM (ABRAMIS BRAMA) FROM POLLUTED AND LESS POLLUTED SURFACE WATERS IN THE NETHERLANDS,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands).
W. Slooff, and D. de Zwart.
The Science of the Total Environment, Vol. 27, No. 2/3, p 149-162, April, 1983. 3 Fig, 7 Tab, 34 Ref.

Descriptors: *Water pollution effects, *Fish, *Bream, *Netherlands, Surface water, Lakes, Rivers, Rhine River, Meuse River, Lake Braassem, Lake IJssel.

The performance of bream from surface waters with different degrees of chemical pollution was studied in terms of growth, fecundity, and mortality. Nearly 7000 bream were examined from the river Rhine and its tributaries, the river Meuse and the Lakes Braassem and IJssel. In the polluted areas of the Rhine and its tributaries, fish showed a higher annual mortality than those from less polluted waters. They also, however, showed a higher fecundity, suggesting a compensatory response to an environmental impact. The growth in succeeding spawning years indicates a significant improvement of growth as the population density of Rhine bream has increased during the last few years. The stress of the impact has been reduced recently. The biological observations correspond with differences in chemical pollution of the surface waters which have been surveyed and with a decrease in the concentration of pollutants in Rhine water during the last decade. ORGANIC CONTAMINANTS IN THE AQUATIC ENVIRONMENT; III. PUBLIC HEALTH ASPECTS, QUALITY STANDARDS AND LEGISLATION,
Imperial Coll. of Science and Technology, London (England). Dept. of Civil Engineering.
N. D. Bedding, A. E. McIntyre, and J. N. Lester.
The Science of the Total Environment, Vol. 27, No. 2/3, p 163-200, April, 1983. 13 Tab, 56 Ref.
Science and Engineering Research Council Grant GR/B/18263.

Descriptors: *Organic compounds, *Water pollution effects, *Literature review, Public health, Water quality control, Standards, Legislation, Drinking water, Environmental effects.

The health aspects and possible risks from the presence of organic micropollutants in water and waste waters are discussed in this literature review. A comparison is made of the quality standards and legislation which have been promulgated by some countries and international oganizations pertaining to the control of certain organic compounds. Different standards may be applied to waters which are designated for particular uses. Quality standards for the protection of the aquatic environment are generally more stringent than those applied to drinking water. Quality standards developed by different countries and organizations display a broad similarity in most cases, but differ where various approaches have been used in determining the toxicity of and hazards presented by individual compounds. Such legislation will become more comprehensive in the future as more substances are included for recommended treatment procedures. (Baker-IVI)

RECREATIONAL WATER QUALITY AND HUMAN HEALTH,
Health and Welfare Canada, Ottawa (Ontario). Health Protection Branch.
A. B. Morrison.
Canadian Journal of Public Health, Vol 75, No. 1, p 13-14, January/February, 1984.

Descriptors: *Reviews, *Water quality, *Recreation, Jurisdiction, Standards, Research priorities, Canada.

A brief review of the First National Conference on Recreational Water Quality and Human Health is discussed. A coordinated effort is necessary for the accomplishment of water quality and human health needs. One mechanism to coordinate federal and provincial activities in the environmental and occupational health field is the Federal-Provincial Advisory Committee on Environmental Health. In developing guidelines for adequate recreational water quality standards it became evident that further research and data-gathering were required. Studies were necessary to determine the association between swimming and microbiological quality of water; investigations on the use of fecal streptococci or enterococci as indicator organisms in bathing beaches; improvement and standardized methods for the isolation and enumeration of viruses in recreational water; improved methods for the isolation and enumeration of pathogens in water; elucidate the extent and degree of recreational water pollution by stormwater and land runoff; obtain communication and cooperation among the agencies responsible for bathing beach water quality. (Murphy-IVI)

VIRUSES AND BATHING BEACH QUALITY,
Institut Armand-Frappier, Laval (Quebec). Centre de Recherche en Virologie.
P. Payment.
Canadian Journal of Public Health, Vol. 75, No. 1, p 43-48, January/February, 1984. 6 Fig, 1 Tab, 15 Ref.

Descriptors: *Viruses, *Water quality, *Bathing beach, Recreation, Enteric viruses, Epidemiology, Bacteria, Enterococcus, Poliovirus, Echoviruses, Wastewater disposal, Wastewater pollution, Surface water, Montreal, Canada.

Enteric viruses are always present in domestic sewage as they are constantly being excreted by infected individuals with or without apparent symptoms. Any recreational water contaminated by sewage will thus contain potentially pathogenic viruses. Epidemiological studies have demonstrated that even in the presence of low numbers of bacteria in bathing water there is an increased risk of contracting gastrointestinal illness. Part of this risk is likely to be due to the presence of viruses which have very low minimal infective doses: for poliovirus and echovirus 12, the 50% infective dose is only 20 to 30 viruses. Calculation of the risks involved in bathing in virus contaminated waters show that a standard of less than 25 viruses/L would bring the number of cases to less than 25/1000 bathers. The absence of viruses in one liter of water would insure that there is less than 1 case/1000 bathers. As the endemic level of gastrointestinal symptoms in the population is 25 to 50 cases/1000 persons, this increase would be undetectable. Such a standard would only be adequate if used in conjunction with the present bacteriological standards and perhaps the addition of an enterococcus standard. (Author's abstract)

OTITIS EXTERNA INFECTIONS RELATED TO PSEUDOMONAS AERUGINOSA LEVELS IN FIVE ONTARIO LAKES,
Toronto Univ. (Ontario). Dept. of Microbiology.
P. L. Seyfried, and R. J. Cook.
Canadian Journal of Public Health, Vol. 75, No. 1, p 83-91, January/February, 1984. 1 Fig, 7 Tab, 35 Ref.

Descriptors: *Otitis Externa, *Pseudomonas Aeruginosa, *Ontario, Lakes, Recreational, Human pathology, Bacteria, Canada.

Studies were undertaken during the summers of 1974 and 1977 to establish the relation of serotypes and phage types of Pseudomonas aeruginosa in recreational water to local cases of external otitis. It was found that there was an increased incidence of infection among swimmers who swam in areas of the lakes where counts were highest. A survey of 424 swimmers and non-swimmers showed that there is a higher occurrence of otitis externa among people under 19 years of age who swim at least five times per week and who have a history of previous ear pathology. GLUCOSE MINERALIZATION ACTIVITY AND THE USE OF THE HETEROTROPHIC ACTIVITY METHOD IN AN ACIDIFIED LAKE,
Laurentian Univ., Sudbury (Ontario). Dept. of Biology.
L. G. Leduc, and G. D. Ferroni.
Water Resources, Vol. 18, No. 5, p 609-612, 1984. 4 Fig, 2 Tab, 17 Ref.

Descriptors: *Glucose, *Mineralization, *Heterotrophic activity method, Acidic water, Bacteria, Glucose mineralization, Hydrogen ion concentration, Ecological effects, Silver Lake, Sudbury, Ontario.

Before a definite conclusion could be made concerning the usefulness of the 'heterotrophic activity method' to measure the rates of decomposition processes in acidic, aquatic environments, it was necessary to study in situ glucose mineralization. Bacterial glucose mineralization samples were taken during the summer from Silver Lake. For Sampling I, linearity between turnover time (t/f) and added substrate concentration (A) did not exist at the in situ pH (3.2) or the experimental pH's (5.5 and 7.0), even though time studies showed that glucose was being mineralized at measurable rates. For Sampling II, modifications were made to the concentrations of labelled glucose and the incubation time. A highly significant linear relationship between t/f and A was demonstrated, and the turnover time and Vmax were calculated to be 472.3 h and 0.005 microg/l/h, respectively. For Sampling III, even though the environmental conditions were similar to those for the previous sampling, a statistically-significant relationship between t/f and A did not result. (Murphy-IVI)

MICROBIOLOGICAL EFFECTS OF WASTEWATER EFFLUENT DISCHARGE INTO COASTAL WATERS OF PUERTO RICO,
Maryland Univ., College Park. Dept. of Microbiology.
D. J. Grimes, F. L. Singleton, J. Stemmler, L. M. Palmer, and P. Brayton.
Water Resources, Vol. 18, No. 5, p 613-619, 1984. 2 Fig, 2 Tab, 24 Ref. NOAA grant NA79AA-D00062, and Office of Naval Research grant N00014-81-K-0638.

Descriptors: *Wastewater discharge, *Ecological effects, *Microbiological studies, *Coastal waters, *Puerto Rico, Fecal coliforms, Coliforms, Bacteria, Chemical wastewater, Domestic wastewater, Streptococcus, Pathogens.

Microbiological effects of non-disinfected, combined chemical and domestic wastewater effluent discharge into coastal waters north of Barceloneta, Puerto Rico were investigated by membrane filter enumeration of fecal indicator bacteria and by enrichment isolation of specific pathogens. A wastewater plume was detected and delineated around the sewage outfall, located 800 m offshore and 30 m below the ocean surface. Fecal coliform and fecal streptococcus counts within the plume were significantly (F test) larger than comparable counts outside the plume. The shape and location of the plume was compatible with current patterns and prevailing winds and extended as far as 3.7 km west of the outfall, at which point the fecal coliform count was 146/100 ml. The average nonplume fecal coliform concentration was < or = 6.7/100 ml. Specific pathogens isolated included Salmonella and Vibrio spp, including V. cholerae non-01 serovar isolated from a nearby river also impacted by the sewage plant. (Author's abstract)

LEAD AND CADMIUM CONCENTRATIONS IN THE HAIR OF FISHERMEN FROM THE SUBAE RIVER BASIN, BRAZIL,
Universidade Federal da Bahia, Salvador (Brazil).
F. Carvalho, T. M. Tavares, S. P. Souza, and P. S. Linhares.
Environmental Research, Vol. 33, No. 2, p 300-306, April, 1984. 1 Fig, 6 Tab, 20 Ref.

Descriptors: *Lead, *Cadmium, *Hair, *Fisherman, Subae River, Industrial wastes, Lead smelter, Metals, Environmental effects, Fate of pollutants, Brazil.

Previous studies have shown heavy pollution by lead and cadmium in the Subae River basin, State of Bahia, Brazil, caused by a lead smelter. Concentrations of these metals were determined in scalp hair of fishermen from three riverside towns and from a reference town. Increased levels for both metals were associated with increasing proximity to the smelter. Mean concentrations of lead and cadmium were higher among fishermen with straight hair than among those with curly hair. The effects of hair washing, hair type, and color and age on metal concentrations in fishermen's hair were studied. (Author's abstract)

CYTOGENETIC EFFECTS OF CADMIUM ACCUMULATION ON WATER HYACINTH (EICHHORNIA CRASSIPES),
Universidad Nacional Autonoma de Mexico, Mexico City. Dept. de Quimica de la Atmosfera y Estudios del Agua.
I. Rosas, M. E. Carbajal, S. Gomez-Arroyo, R. Belmont, and R. Villalobos-Pietrini.
Environmental Research, Vol. 33, No. 2, p 386-395, April, 1984. 1 Fig, 5 Tab, 63 Ref.

Descriptors: *Cytogenetic effects, *Cadmium, *Water hyacinth, Accumulation, Bioindicators, Water pollution effects.

Cadmium was bioassayed to observe cytogenetic effects in the water hyacinth (Eichhornia crassipes). Plants were exposed for 96 hr to freshwater containing 0.01, 0.05, 0.10, 1, 5, and 10 mg/liter of cadmium. Metal concentrations in tissues were determined by atomic absorption spectrophotometry. The highest level was found in roots, thus root-tip cells were used for cytogenetic studies; after 24 hr of exposure, micronuclei, c-mitotic effects, and pycnosis were detected and after 48 hr polyploidy was observed. A linear relationship between frequencies of micronuclei and cadmium concentrations was found; at 1,5, and 10 mg/liter micronuclei numbers were always the lowest. The inhibition of cell proliferation, shown by the low mitotic index, was proportional to the concentration and time of exposure. It may be concluded that water hyacinth is a good sensor, due to its fast rate of metal accumulation, which allows an easy way to determine the presence of potential mutagenic compounds in water. (Murphy-IVI)

DILEMMA OF AN ACIDIC SKY,
Kellogg Corp., Littleton, CO.
T. Jenkins.
American Water Works Association Journal, Vol. 76, No. 3, p 42-49, March, 1984. 3 Fig, 61 Ref.

Descriptors: *Water pollution effects, *Acid rain, Sulfates, Nitrates, Reviews, Water pollution sources, Acidity, Forests, Lakes, Rivers, Legislation, Clean Air Act.

The damaging effects of acid precipitation in North America and Europe are reviewed, followed by a commentary on the controversial political and economic issues associated with forestalling deterioration of the environment. Acid rain refers to the deposition of atmospheric pollutants on soils, vegetation, surface waters, and man-made objects ultimately causing damage because of the pollutants' acidity. Apparent sources of acid atmosphere are primarily human activities. The effects on lakes, rivers, and forests are described. It has been estimated that acid rain causes as much as $5 billion annually in environmental damage, mostly in the northeastern United States and Canada; reducing emissions will cost from $3 to $7

billion annually. Proposed amendments to the Clean Air Act are listed. A comprehensive bibliography is included. (Baker-IVI)

EFFECTS OF ACID PRECIPITATION RUNOFF ON SOURCE WATER QUALITY,
Institute for Research on Land and Water Resources, University Park, PA.
R. T. Leibfried, W. E. Sharpe, and D. R. DeWalle.
American Water Works Association Journal, Vol. 76, No. 3, p 50-53, March, 1984. 2 Fig, 17 Ref.

Descriptors: *Water pollution effects, *Acid rain, *Runoff, *Water quality, Jennerstown, Boalsburg, Pennsylvania, Drinking water, Aluminum, Ryznar Stability Index.

During episodes of acid runoff in February of 1981 and March of 1983, the quality of water in two small streams that provide supplies to the water systems of Jennerstown and Boalsburg, Pennsylvania was monitored. A small impoundment on Card Machine Run provides part of the water for the village of Jennerstown, and Galbraith Gap Run supplies water to a small impoundment that is the main source of water for the town of Boalsburg. Changes in pH, in the concentration of aluminum, and in the Ryznar Stability Index were determined. The magnitude and potential importance of these changes are discussed. Differences in water quality between these two watersheds may have been due to differences in soils, geology, and long-term loadings of acid precipitation on these areas. It is unclear as yet whether the observed changes in source water quality will produce similar changes in the quality of tap water provided to customers in the systems studied. (Baker-IVI)

CURRENT RESEARCH ON THE EFFECTS OF ACID DEPOSITION,
Minnesota Univ., St. Paul. Dept. of Forest Resources.
J. A. Perry.
American Water Works Association Journal, Vol. 76, No. 3, p 54-59, March, 1984. 2 Fig, 1 Tab, 22 Ref.

Descriptors: *Water pollution effects, *Acid rain, Emissions, Corrosion, Heavy metals, Metals, Forests, Catchment areas, Water distribution.

Preliminary research aimed at quantifying relationships between emission and acid deposition and on-the-ground effects indicates that small water supplies fed by surface waters or shallow wells and cistern supplies may be adversely affected by acid deposition. Research on acid deposition must address issues such as atmospheric chemistry, distance of transport, and deposition monitoring, in addition to the study of a wide range of other effects. Any decision about methods of controlling acid deposition will ultimately be made on the basis of the effects, and those effects may be real or perceived. Research includes such diverse arenas as a forest canopy's interaction with acidic mists, the geochemistry of stream environments, and the effects on building materials and on the preservation of artifacts, such as the Statue of Liberty, that are located outdoors. Public health aspects, including potential effects on domestic water supplies, are being actively studied. Acid deposition may affect water supplies in three ways: delivery of contaminated water to the catchment, mobilization of contaminants within the catchment, and mobilization of contaminants by corrosion of distribution systems.
